With reference to the danger of sepsis following intra-uterine treatment, I regard it as trivial. I have had no trouble with my cases, nor do I have constitutional disturbances after passing the sound. I attribute this to painstaking and constant care in cleansing my electrodes and sounds each time before introducing them, and also to the fact that it is my habit to either douche or wipe out the vagina with a strong antiseptic (corrosive, 1 to 2,000; creolin, 1 to 500; lysol, one per cent.) previous to any intra-uterine instrumentation, whether electrical or otherwise. To this fact, more than to great gentleness in passing the instrument, I attribute my immunity from septic trouble. Although the micro-organisms in the vagina are not all destroyed by the antiseptic, their number is lessened and their activity diminished, and fewer are carried into the uterine cavity. The antiseptic action of the positive pole is also a factor in guarding against sepsis. Apostoli has proved this.

Dr. Davenport has spoken of the good results he has obtained by the use of methods other than electricity. It seems to me that the profession is in need of facts and figures bearing on this matter. I, for one, wish that some one, having in view the object of reporting results, would follow up for a reasonable length of time a series of cases treated by these methods, and also cases not treated at all. The data so gained would be of the greatest value. Personally, I place reliance on electricity.

As Dr. Richardson has said, if electricity can be used in getting patients who are worn out by years of suffering in proper condition for operation—patients, who, if operated on at once, are almost sure to die—it has great value. I can assure him that electricity

has been many times so used. It is a means of lowering the mortality of hysterectomy. Many patients are so much improved after a course of electrical treatment that they do not need hysterectomy, whereas others do not receive permanent benefit. Electricity does no harm and may do great good.

In treating fibroid tumors, we have to face a complicated and difficult problem. It is seldom that we can say, the first time we see a patient, hysterectomy or nothing. We must do the best we can to relieve suffering. Because too much has been claimed for electricity is no reason why we should refuse to avail ourselves of the good that it surely can do.

DR. EDWARD REYNOLDS reported

A CASE OF CONCEALED ACCIDENTAL HÆMORRHAGE DURING FIRST STAGE OF LABOR, WITH RECOVERY OF MOTHER UNDER CONSERVATIVE TREATMENT.¹

DR. A. WORCESTER wished to ask whether the reporter considered the mother's jaundice due to the absorption of the coloring matter in the blood-clot in the uterus. He did not see how that was possible.

DR. C. W. TOWNSEND said that in regard to the rapidity of maceration after the death of the child, he had seen a case of transverse presentation where the child was alive and where the mother refused to have any operation done. He saw the case twenty-four hours later when she was brought to the Lying-in Hospital. Here, the child was delivered by version and was not only dead, but the skin was slightly macerated. The speedy maceration here might be due to the fact that the membranes had ruptured early.

DR. A. WORCESTER said he could go even further than this, for he had once delivered a child whose skin was macerated that lived.

**MASSACHUSETTS MEDICAL SOCIETY.
SUFFOLK DISTRICT.
SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.**

HENRY JACKSON, M.D., SECRETARY.

REGULAR Meeting, Wednesday, January 17, 1894.
DR. F. C. SHATTUCK in the chair.

DR. R. C. CABOT presented a paper on
THE DIAGNOSTIC AND PROGNOSTIC VALUE OF LEUCOCYTOSIS.¹

DR. M. H. RICHARDSON: I should like to say a word in regard to the application of this method to surgical diseases. Dr. Cabot examined the blood in many of my cases this past summer, and his conclusions were almost invariably correct. Several of the cases which he has quoted were in my wards. With one exception we found pus every time the blood-count indicated it. Of course, in many instances we can tell well enough whether there is pus present or not without any such investigation; in other cases we cannot be sure, especially in the secondary abscesses which sometimes follow the drainage of appendicitis, in which one is very unwilling to stir up the abdomen without good reason. In one case referred to by Dr. Cabot, in which an appendix was removed at the end of the attack, there was a small amount of pus. Dr. Cabot is mistaken in regarding this case as aseptic.

¹ See page 277 of the Journal.

¹ See page 284 of the Journal.

The patient, a young man, had developed very serious symptoms some time after the appendix had been removed. There was nausea and vomiting, with pain and tenderness. The pulse and temperature were elevated. Yet beyond the probability of pus deeply seated somewhere, we could form no definite opinion. Dr. Cabot examined the blood, and found a leucocytosis that indicated pus. We therefore felt justified in exploring the wound—an operation which should be undertaken only when clearly indicated. Dr. Conant operated for me twice, and the boy recovered. The amount of pus was very large; it was deeply seated and gave no physical evidence of its situation. The only instance in which we were mistaken was a case of general peritonitis following appendicitis. My diagnosis the first day was appendicitis, and I advised immediate laparotomy. The others thought it was some acute condition not demanding interference; moreover, Dr. Cabot found no leucocytosis. Inasmuch as he had been invariably correct in previous cases, I decided not to operate. On the following day, for other reasons, we opened the abdomen. Dr. Shattuck on that day made the correct diagnosis of appendicitis with general peritonitis; I, meantime, changed my opinion. The patient's abdomen was distended with a very septic fluid; there was a gangrenous and perforated appendix, with a general purulent peritonitis. He died in the course of twenty-four hours.

From the surgical standpoint this subject is a very promising one. There is a very intimate connection between a leucocytosis and the presence of pathogenic micro-organisms. From the valuable work that Dr. Cabot has done, the treatment of patients has already been very materially improved. Further researches will undoubtedly give this method of investigation a still greater value in its practical application.

A question that arises frequently is, whether or not there is pus in the abdomen or in some of the closed cavities beyond reach. Now, if by such an examination as this we can be sure that, for instance, there is a perforation of the appendix or pus deeply seated in the abdomen, the vexed question of interference is decided at once. Moreover, if an expert examination of the blood is able clearly to demonstrate a condition of septic absorption; if, in connection with other symptoms, it can show unmistakably that there is a deep-seated focus of pus in the abdomen, in the thorax, in the head, or in a joint, it seems to me that we have added to our resources in diagnosis one of the most important and valuable aids of recent years.

Personally, I feel much indebted to Dr. Cabot for the work which he has done.

DR. F. C. SHATTUCK: I cannot forbear adding a word in expression of my appreciation of and interest in this paper. As I have watched Dr. Cabot's work in my ward and among my patients, I have learned to attach much value to this study which seems to me to promise great things for us in the future when thoroughly worked up.

DR. MASON: The very great interest of this subject is certainly apparent, and I have listened with great pleasure to the paper. There are one or two questions I should like to ask. In speaking of purulent meningitis, I suppose that would include the epidemic cerebrospinal form?

DR. CABOT: Only two counts were made.

DR. MASON: In that affection there is a good deal of purulent secretion within the head and spinal canal.

Cases are rare with us now; sometimes there is difficulty in determining the diagnosis with accuracy. I should think that blood examination would be very valuable. In one other affection I lately have been interested in having the blood counted; that was in a case of Graves's disease; and I should like to ask Dr. Cabot if, in his researches, he came across any statement with regard to that affection. Of course, it is pretty well known that internal abscesses give rise, as a general thing, to a greater or less degree of leucocytosis. In one case last year, or the year before, a liver abscess was explored for two or three times, and finally found, the blood-count having shown a high degree of leucocytosis. In the one case of Graves's disease I have observed there was no increase in the white elements.

DR. CABOT: I have counted only one case of Graves's disease, and in that the blood was normal. In those about which I have read the blood has been normal as far as the quantitative changes of the red to white were concerned.

Recent Literature.

Hand-book of Insanity. For Practitioners and Students. By DR. THEODORE KIRCHHOFF, Physician to the Schlerwig Insane Asylum and privat-docent at the University of Kiel. New York: Wm. Wood & Co. 1893.

Text-books on insanity are often abstruse through the use of new or unfamiliar terms, technical expressions and complicated classifications, which make them heavy reading for the student and general practitioner. When one appears, therefore, that is practical, simple and concise in statement, well arranged, accurate and complete in the consideration of the various aspects of mental disorder likely to interest the general physician, we have the model book for instruction. Such is the hand-book before us—a scientific work by an alienist of ability and experience and powers of observation and insight of a high order. It is up-to-date, clear in style, brief and correct. At the same time, its 358 pages are more complete in the number of subjects and points considered than any work we call to mind that is not an elaborate treatise on the disease. It is also a decided advantage that the space devoted to each subject is for the most part in direct proportion to its importance. The fact that it contains no allusion to the jurisprudence of insanity may be accounted for by the class of readers for whom the work is designed. The author's classification of the forms of insanity is a brief clinical one, which, if possibly too simple, has no more flaws than are common to all attempts to bend partially understood pathological conditions of the nervous system to a natural system of nosology.

The numerous illustrations are well executed and more than usually characteristic of the different forms. As a rule, there is more than one picture of the same patient in different aspects or stages of the disorder. These, with the explanations given in detail of the cause and import of the expressions and attitudes depicted, greatly enhance the value of the text.

To condense from the original so extensively, and at the same time to preserve and perhaps improve upon its simplicity and clearness, shows no ordinary

skill in translating and book-making. It is indeed surprising that under the circumstances so few obscurities have crept in. It is unfortunate that a poor index should mar, as it does, such a serviceable book.

The publishers contribute generous pages, good paper and clear type.

Supplement to the Reference Hand-book of the Medical Sciences. By various writers. Illustrated by Chromo-lithographs and fine Wood-engravings. Edited by ALBERT H. BUCK, M.D. Vol. IX. New York: William Wood & Co. 1893.

The original eight volumes constituting the "Reference Hand-book" were published between 1885 and 1889. In some departments of medical knowledge—notably in Pathology, Materia Medica and Therapeutics—there have been very considerable changes in and additions to our knowledge since then. The present supplement was undertaken in order to bring the hand-book as far as possible up to date without superseding the original work. In addition to a revision of previous articles, some articles on entirely new subjects, not previously discussed, have been incorporated. This volume contains 1,100 pages. There are 122 contributors. Many of the illustrations are very good. As a rule, the standard attained in the original volumes has been well maintained. The editor's work has been done with judgment and discretion.

The Theory and Practice of Medicine. Prepared for Students and Practitioners. By JAMES T. WHITTAKER, M.D., LL.D., etc., with a Chromo-lithographic Plate and three hundred Engravings. New York: William Wood & Co. 1893.

The author of this book is the professor of the subject about which he writes, in the Medical College of Ohio. The volume is an octavo of eight hundred pages. The first part is devoted to general diseases, takes up nearly half of the book, and is the most thorough. The second part is devoted to diseases of organs. Diseases of the nervous system occupy three chapters; and this is perhaps the least satisfactory part of the volume. The illustrations are numerous and of varying merit. The letter-press and paper are very good. A number of the chapters are condensed or adapted from the author's previous contributions to hand-books, systems or text-books of medicine.

Diseases of Childhood (Medical). By H. BRYAN DONKIN, M.A., M.D. Oxon., F.R.C.P., East London Hospital for Children, at Shadwell; Physician and Joint Lecturer on Medicine and Clinical Medicine, Westminster Hospital. New York: William Wood & Co. 1893.

In his new work on the medical diseases of children Dr. Donkin has made a most valuable contribution to our literature. It is in no way a compilation, but is the result of the author's own clinical observations, well put together and carefully analyzed. He has indeed adhered to his personal experience so closely as to omit any account of variola and the general subject of cutaneous affections, with which he says he has had but little to do. He has, however, in an appendix given us a summary of the conclusions from the latest report of the Clinical Society of London, and the incubation and contagious periods of the commoner infectious diseases, which is an admirable addition.

The fine press-work of this neat volume renders it all the more attractive.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, MARCH 22, 1894.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 233 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMBELL & UPHAM,
233 WASHINGTON STREET, BOSTON, MASS.

PROPOSED REDUCTION OF THE ARMY MEDICAL DEPARTMENT.

THE following are extracts from the draft of a proposed Army Appropriation Bill for the fiscal year beginning July 1, 1894, as submitted to the full Committee on Military Affairs by the Sub-Committee:

"Provided, That hereafter no appointment shall be made to the office of assistant surgeon-general with the rank of colonel until the number of such assistant surgeons-general shall be reduced below four, and thereafter the number of officers in that grade in the Medical Department shall be fixed at four; and no appointments shall be made to the office of assistant surgeon-general with the rank of lieutenant-colonel until the number of such assistant surgeons-general shall be reduced below six, and thereafter the number of officers in that grade in the Medical Department shall be fixed at six; and no appointments shall be made to the office of surgeon with rank of major until the number of such surgeons shall be reduced below thirty, and thereafter the number of officers in that grade in the Medical Department shall be fixed at thirty; and no appointments shall be made to the office of assistant surgeon until the number of assistant surgeons shall be reduced below ninety, and thereafter the number of officers in that grade in the Medical Department shall be fixed at ninety."

Fortunately the House Military Committee has listened to reason, and admitted the weight of argument against this proposal, and has abandoned the idea of reducing the number in the upper ranks of the medical corps; but it still proposes to cut off thirty-five assistant surgeons, bringing these down to ninety. This is by no means so bad (at least in its immediate action) as the original bill submitted by Mr. Outhwaite, of Ohio, Chairman of the Committee, from which we have quoted above. That bill, had it become law would have reduced the medical department two colonels, four lieutenant-colonels, twenty majors, and thirty-five junior officers; would have stopped all promotions and appointments in the corps for about eight years; and would have greatly injured the department. The present modified proposition, however, is bad enough, and is, from an economical point of view, unwise.

There are now barely enough medical officers to supply Posts, and it is forbidden to employ acting assistant surgeons. Moreover, when a competent physician has served in the army thirty-two or thirty-three years, as the ten senior army surgeons ranking as majors have done, he ought not only to have the chance to be paid a lieutenant-colonel's salary, but he also ought to feel secure in his position.

It is very desirable to have first-rate men in the army medical corps, men who may be detailed for important and delicate services; but to such the corps is already none too attractive. It now has six vacancies. Under such circumstances that is poor economy which threatens to lower the standard.

The idea of the promoter of this measure (for we credit him with some other purpose than simply posing as a watch-dog of the treasury) seems to be to retain merely a skeleton of an army medical corps in times of peace, and to supplement its deficiencies in time of war by surgeons drawn from civil life. This would be very poor economy. The civil surgeon may be available when wanted; he may know how to amputate a leg, dress a wound, or extract a bullet as well as the army surgeon, but he does not know the routine (call it red tape if you will) of the army service and of government bureaus. He does not know and cannot be expected immediately to know, how to provide and care for those under him. He is summoned when the emergency is great and immediate action is required. The hopeless and costly confusion existing in some of the government pension rolls to-day is partly due to this very thing. It has cost our taxpayers millions of dollars, which would have paid the salaries of many medical lieutenant-colonels, majors, etc., and still left much over to be appropriated in those forms of gross extravagance, such as river and harbor bills or sugar bounties, which are less vexing to the pious souls of Congressmen. There are two members of Congress from New England upon the House Military Committee, Mr. Gillett from Springfield, Massachusetts, and Mr. Lapham, from Rhode Island. We hope they may hear from their constituents in regard to this proposal. This is a matter in which the medical profession at large ought to interest itself.

RECENT INVESTIGATIONS OF THE BRITISH GOVERNMENT UPON THE INFLUENCE OF CERTAIN TRADES OR OCCUPATIONS UPON HEALTH.

DURING the past year special committees have reported to Parliament upon different industries of a dangerous character in which legislation seemed to be necessary for the protection of persons employed in them. The industries which were the subjects of report were the lead industries, lucifer-match works, potteries, chemical works and stone quarries.

Lead Industries.—This committee was directed to inquire (1) into the conditions under which lead smelting, the working of blue lead, and the production of

white lead, red lead and yellow litharge are conducted, with the object of diminishing any proved ill-effects upon the health of the work-people engaged therein; (2) whether the special rules which already exist with regard to the manufacture of white lead are sufficient; and (3) to suggest any precautions necessary to the industries specified for the protection of life or health. The committee was also charged with conducting farther special inquiries, including an investigation of the cause of death of a young woman engaged in lead-works.

In summing up the recommendations, which are very numerous and minute, the committee calls attention to the fact that the works in which the largest number of cases of lead-poisoning has occurred are those in which there has been the least expenditure of money and care in precautionary measures for the health of the operatives.

The greatest change which is recommended is the exclusion of females from all direct contact with white lead. The committee also records, as the result of its experience, the fact that lead, and all its compounds are in a greater or less degree poisonous, and that the handling or use of each or all of them is attended with danger.

Potteries (China and Earthenware).—This committee concludes that the potter's trade is attended with injury to health and life. The ill-effects are due to two causes: dust, and the poison of lead. The former is of wider action, since it pervades all the operations or processes wherein potter's clay and flint powders are in use. The latter prevails in the departments of work concerned in the glazing and coloring of the ware, after it leaves the hands of the potter. A third but less potent cause exists in the operations necessary to the completion of the ware by firing.

The committee presents statistics in support of their conclusions, showing that the inhaling of the noxious dust of clay and flint is a fruitful cause of diseases of the respiratory organs. The mortality returns of Stoke-upon-Trent for 1890 show that, of the males over fourteen years of age who were potters, 42 per cent. died of bronchitis, 8 per cent. of pneumonia and pleurisy, and 21 per cent. of phthisis. In a general way it was also shown that only 4.5 per cent. of potters died of senile decay, and 12.5 per cent. of persons who were not potters, a fact which shows that potters generally die young.

The committee found that much of the mortality from lead-poisoning was avoidable, although no code of regulations could entirely obviate the effects of the poison to which the workers were exposed.

The following modes were indicated by which the poison gains access to the body: (1) by eating food with unwashed hands, or partaking of it in the rooms where lead is dealt with; (2) by neglect of cleanliness of clothing; (3) allowing glaze and colors to drop about, become dry, and so form dust which is inhaled; (4) holding the pencil used in painting, in the mouth, as is done by women employed in majolica painting;

(5) rubbing the eyes with dirty hands; (6) near-sight-ness, causing the workers to be too close to their work; (7) constitutional idiosyncrasy, producing excessive susceptibility to lead-poisoning.

The committee formulated a code of regulations which, if established and enforced in every pottery, would greatly diminish the injurious effects of the different processes of manufacture. These rules had reference mainly to personal cleanliness, and the cleanliness and ventilation of the work-rooms, the employment of females and children under fourteen, and the eating of food upon the premises.

Lucifer-Match Works.—The special danger to which persons engaged in the manipulation of phosphorus are exposed, is necrosis. The committee appointed to consider this trade recommended several rules. These provided for the isolation of certain processes from other parts of the factory, with thorough ventilation in apartments where such processes were conducted; that hot and cold water, soap, nail-brushes and towels should be furnished, and the operatives required to use them; that all workers should be examined, at least once a month by a surgeon, who should have power to order temporary suspension or total change of work for any one showing symptoms of incipient necrosis; that all persons complaining of toothache or swelling of the jaws should be examined at once; that no person should be permitted to work in the processes of mixing, dipping, drying or boxing, after the extraction of a tooth, without the certificate of a duly qualified medical practitioner, that the jaw is healed. Penalties were recommended for neglect to comply with these rules.

Chemical Works.—The committee upon these industries was charged with duty of inquiring "into the dangers to life, limb and health attending employment in chemical works," with a view to discover "(1) how far the manufactures, as at present carried on, injuriously affect the health of the work-people, and how far the injurious effects depend on the age and sex of the operatives; (2) what means can be adopted to abate the injurious effects of the manufacture; (3) what special regulations should be adopted to protect vats and other dangerous places and utensils used in the manufacture."

The manufacture of bleaching-powder is by far the most harmful to the operatives, of any department of chemical work. Lime is treated in chambers with chlorine gas, which is absorbed by the lime. At the end of four days the doors are opened, and men enter the chambers to pack the lime. In disturbing the powder free chlorine gas is let loose. The packers are obliged to wear respirators or muzzles of thirty folds of damp flannel, tightly tied over the mouth, the nose being free; the men inhale through the muzzle and exhale through the nose. If they happen to reverse the process they became "gassed." The exertion of breathing through the thick folds of flannel shows itself in the red and puffed state of the men's faces and profuse perspiration in coming out of the

chambers, which they are obliged to do at intervals. The lime-dust also injures the eyes. None but robust men could endure this work. The sufferings of these operatives are vividly portrayed in the "minutes of evidence."

Question 22,515. What you suffer from is the escape of chlorine gas, I suppose?

Yes, that is what we suffer from. When we go into the chamber, sometimes we are not able to stop there five minutes, sometimes a quarter of an hour, sometimes half an hour, sometimes you cannot stop two minutes.

Question 22,556. Have you anything further you would like to say to the Commission?

I have got the muzzle with me. (Witness puts on the muzzle.)

Question 22,557. Whenever you are packing in a hot chamber you are obliged to use that?

Yes.

Question 22,558. And no man could enter the chamber without it?

No! they could not put their noses inside.

Question 22,559. It is nothing but ordinary flannel?

Yes.

Question 22,560. Several folds of ordinary flannel?

Yes; it must be the best flannel. It has to be renewed; it gets eaten away with the gas.

In another inquiry of the same character, made by an English trade-journal, a workman said: "Every man is liable to a visit of the gas right through the muzzle." Gassing is such a common matter that the men readily describe its symptoms. "Is it ever fatal?" — "Yes, sometimes."

A workman's clothes-bill for a fortnight amounted to fifteen shillings. The shirt was torn, and in several parts hung in strips. It was hardened by acid or powder, and tore freely. This shirt had seen two days' work, and was now good for nothing.

"If a premium of £100 were to be offered by the alkali magnates, there would be clothing (diving-suits) put together in no time, with proper air-pumps, and an anti-corrosive coating which would resist the rasping and tearing of the dust and gas. The directors might do worse than keep the photographs of the powder-packer's head, which appeared last week, on their breakfast-tables and in their board-room, just as a reminder."

In the salt-cake (sulphate of soda) department, the danger is from the escape of hydrochloric-acid gas. Many workmen have had their teeth entirely destroyed by its effects.

In the manufacture of caustic soda, the danger results from the splashing of the liquor, and frequent injury to the eyes.

In the manufacture of chlorates, the chief danger is from explosions, and the saturation of the clothing with the dust and its taking fire.

In making bichromate of potash and soda, the committee found that almost all the men working where dust was prevalent had either perforation of the septum of the nose, or had lost the septum altogether. These results often cause partial or complete loss of the sense of smell, with irritation and ulceration of the throat,

trachea and bronchial tubes. Many of those employed suffer from what are called "chrome holes" in their hands and arms, caused by dust or liquor acting on the broken skin, or by handling the crystals.

The medical officers of the commission suggested the following as means of lessening the evils of working in the bleaching-chambers:

(1) Free and thorough ventilation in and about the bleaching-chambers.

(2) Oiling or greasing the exposed parts of the body before beginning work, the wearing of "goggles," and the introduction at intervals of a few drops of oil into the eyes for their protection.

(3) Let the respirators be moistened from time to time with a solution of sulphide of soda. If this suggestion were carried out, the "muzzles" might be made much thinner than at present, and the men could breathe with greater freedom and safety.

To obviate the evils caused by the inhalations of the dust of chrome compounds, the following is advised: Let the sponge or other absorbent material of the respirator be moistened with a solution of bismuth (Liquor bismuthi, B. P.). The chrome dust coming in contact with this is decomposed. The same result might be attained by plugging the nostrils with cotton-wool, moistened in the same solution. Frequent washing of exposed parts of the body is desirable, and protection of the hands with water-proof gloves.

Stone Quarries. — The committee upon this subject was required to report upon the dangers to life, limb and health, attending employment in open quarries. The field of inquiry included operations conducted in nearly every county of the kingdom, the number of persons thus employed in 1891 being 121,637; but the sessions of the committee of which the minutes of evidence are published, were mostly held in the quarry-regions of Wales.

Dr. Ogle, of the Registrar General's Office, who appeared before the committee, stated that the mortality of quarrymen from phthisis and respiratory diseases was very high (three times as high as that of fishermen), and that, in his opinion, this excessive mortality was due to the inhalation of stone-dust.

MEDICAL NOTES.

THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF PENNSYLVANIA. — There are 801 active students in the Medical Department of the University of Pennsylvania this term, 45 less than last year, which was the largest number yet registered.

THE DEATH OF MRS. CHARLES L. DANA. — Dr. Charles L. Dana, of New York, will have the sympathy of his personal and professional friends in his recent bereavement in the loss of his wife, who died in Bermuda on March 8th, from injuries received in a carriage accident.

THE POSSIBILITIES OF CHEMICAL NOMENCLATURE. — The possibility for a chemist to tell all that is

in a substance by its name, is well illustrated by one of the new synthetic remedies, which has the simple cognomen of monosodic methylamido brommethyl propylamine-benzol.

CHOLERA IN TRIPOLI.—Cholera is officially reported to have broken out at Tripoli. Several cases of the disease have occurred in the military hospital outside the town.

INFLUENZA AT GENOA.—During the past month the influenza has been violently epidemic at Genoa. Over twenty thousand cases have been reported to the health authorities, and the daily mortality of the city has risen from twelve to fifty.

SMALL-POX ON A UNITED STATES WARSHIP.—Information has been received from China that the United States warship *Monocay* reached Woe Sung from Chin Kiang on the 11th of February with several cases of small-pox on board. Six of her crew were taken to the general hospital at Shanghai.

THE CHICAGO CURSING DOCTOR.—A "Doctor" McFadden died recently in Chicago, who had not a little reputation as a cursing doctor. His sole method of treatment was by laying on of hands and swearing at the evil spirit or disease until it left the patient. His cursing was not a simple exorcism, but was genuine Billingsgate, unpurged and unrefined. He had a large and rather lucrative practice.

THE DIAGNOSIS OF APPENDICITIS IN A TIGER.—A tiger in a Wisconsin circus was recently operated upon for "appendicitis." According to the newspaper account, "He clawed his abdomen so that it was guessed he had the disease. He was securely chained and muzzled, and a doctor cut into him. In the inflamed sac was found the rim of a pair of spectacles. The tiger foamed with rage while the operation was in progress."

CHOLERA INSURANCE FOR RUSSIAN PHYSICIANS.—In the Russian province of Wiatka, a resolution was recently adopted at a general meeting of the citizens for insuring the lives of medical and surgical practitioners against cholera. From the funds of the province on deposit in the imperial bank, the family of a physician practising within the province will receive upon his death by cholera the interest on 5,000 roubles, or on 8,000 if he has practised within the province ten years. A surgeon's family will receive the interest on 1,000 roubles.

CANNED VEGETABLES CONTAINING POISON.—In the course of investigations made last year by the Chemical Division of the Department of Agriculture 80 samples of canned and bottled peas were examined, 43 of American and 37 of foreign origin. All of the foreign brands, except two, contained copper; one contained zinc. Fourteen of the 43 American samples contained copper; 29 did not. Salicylic acid was present in five French and 10 American samples. Tin was present in 50 samples, lead in 50, and zinc in 15. In all, 248 samples of all sorts of vegetables were examined, and in no less than 121 was salicylic acid

detected. Zinc was found in 40, copper in 88, and lead in 182.

THE NEW YORK PASTEUR INSTITUTE.—The statistics for the preventive treatment against hydrophobia of the New York Pasteur Institute for 1893 show that there were 26 patients who were bitten by animals in which hydrophobia was evidenced by experimentation or by the death of some other person or animal bitten by them; 11 patients who were wounded by animals recognized as rabid by clinical or veterinary examination; and 48 bitten by animals in which rabies was suspected, but who were killed or lost sight of before any proof was obtained. No deaths occurred in any of the patients. Forty-five of them had had the wounds cauterized before entrance, but in all cases in an insufficient and non-efficacious manner. The 104 patients treated in 1892 have all remained free from disease up to the present time.

ANOTHER DANGEROUS PASTIME.—Another good out-door sport has been added to the list of dangerous games, fortunately before it has become so deeply rooted in the affections of our youth that they cannot be kept from its harm. Golf-playing is the cause of severe gluteal strain, with possible rupture of fibres in the anterior portion of the muscle which is made over-tense in the position of "driving strokes." Two such cases have been reported already in the *Lancet*.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—During the week ending at noon, March 21, 1894, there were reported to the Board of Health of Boston, the following numbers of cases of acute infectious disease: diphtheria 31, scarlet fever 33, measles 26, typhoid fever 13, small-pox 6 (2 deaths). There are now 15 patients in the Canterbury Street Small-pox Hospital. During the week 9 cases of small-pox were reported to the State Board of Health from Holyoke.

A SCHOLARSHIP IN MEMORY OF DR. CHARLES PRATT STRONG.—A number of friends of the late Dr. Charles P. Strong, of Boston, have given to Harvard University the sum of \$3,750 to found a memorial scholarship in the Medical School. For the present, all income from this sum over one hundred dollars is to be added to the principal until that reaches five thousand dollars.

THE MEDICAL REGISTRATION BILL BEFORE THE MASSACHUSETTS LEGISLATURE.—A majority of the Committee on Public Health have reported to the Legislature a bill to control (?) the practice of medicine in this State. A minority, among whom is Senator Harvey, of Worcester County, have offered an adverse report.

MEASLES, JUDGMENT AND DISCRETION.—A suburban board of health offers the following piece of wisdom, as advice to the people whom it is called upon to protect: "The Board is of the opinion that it is not wise to try and stop the spread of measles among children, for it is one of the diseases that a large majority of the people are liable to have during their lives, and

it is a well-settled fact that it is more dangerous and troublesome with older people than with the young." And furthermore the same board says: "It is very important that men of *experience, judgment and discretion* should be selected," as members of boards of health.

How does the foregoing statement appear in the light of the following facts, taken from the State Registration Report for the year 1890 (page 321)? Number of deaths from measles in Massachusetts, for the twenty-eight years ending with 1890, 5,649; of this number 5,078, or 89.8 per cent., were children under ten years of age; and 4,581, or 81 per cent., were children under five years of age.

REQUESTS TO MEDICAL CHARITIES.—The will of the late Rufus S. Frost bequeaths the sum of one thousand dollars to the Chelsea Day Nursery, and five thousand dollars to the R. S. Frost General Hospital for the establishment of a free bed.

A GENEROUS BEQUEST TO YALE UNIVERSITY.—The will of Mr. Richard S. Ely of New York, after leaving many bequests to charitable institutions, creates of the remainder of his estate a trust for Yale University, the income to be used to found professorships in the medical, law and academic departments. The estimated value of this trust is between fifty and one hundred thousand dollars.

NEW YORK.

TWO DRACHMS OF MAGENDIE'S SOLUTION GIVEN BY MISTAKE.—At the New York Hospital one of the female nurses recently gave a patient two drachms of Magendie's solution of morphia by mistake, in consequence of which he died. The man, whose name was Conway, was suffering from fracture of the skull and other injuries, the result of a fall from the elevated railroad, on which he was employed as a track-walker. It is believed, however, that the injuries would have proved fatal had the morphia not been given. At the inquest the nurse stated that at about 8.30 P. M., one of the house-staff of surgeons administered a hypodermic injection of Magendie's solution to a patient in the bed next to Conway's, after which the bottle was handed to her to place in a medicine cabinet. A few minutes later she administered to Conway two teaspoonfuls of what she supposed to be the old U. S. P. morphia solution of the strength of a grain to the ounce. When he had swallowed it she discovered that she had given him Magendie's solution instead, and notified the doctor. The stomach pump was employed and other appropriate measures taken, but during the night the man died. Dr. Donlin, the coroner's physician who made the autopsy in the case, expressed the opinion that Conway could not possibly have survived his injuries, and stated that he found that the base of the skull was badly fractured and the tissue of the brain severely lacerated; in addition to which the clavicle and four of the ribs were broken.

A BILL TO ESTABLISH A STATE COLONY FOR EPILEPTICS.—There was a hearing March 7th on the bill now before the legislature, to establish a State

colony for epileptics. The scheme as perfected in the pending bill has the strong endorsement of the State Board of Charities, the State Charities Aid Association, the State Commission in Lunacy, and the Convention of Superintendents of the Poor.

AN OUTBREAK OF TYPHOID FEVER AT BUFFALO.—A serious outbreak of typhoid fever has occurred at Buffalo. Up to March 15th there were reported 236 cases and 20 deaths. There seems to be no doubt that the disease is due to the impurity of the water supplied to the city, and on March 18th the Mayor called an emergency meeting of the Board of Health to take measures to suppress the epidemic. It seems that three weeks before the cases of typhoid commenced to develop, the Water Department, in filling a new reservoir, took water from what is known as Bird Island inlet, a source of supply which is contaminated by city sewage, and which was last autumn condemned on this account by Health-Commissioner Wende.

A BEQUEST TO ST. LUKE'S HOSPITAL.—By the will of the late Richard S. Ely, the sum of \$90,000 is left to various charitable objects. The largest single bequest is that to St. Luke's Hospital, amounting to \$20,000.

Miscellaneous.

THE DERMATOLOGY OF TO-DAY.

In his presidential address delivered before the Harveian Society of London,¹ Mr. Malcolm Morris, reviewing the progress recently made in dermatology, said:

"The change, not merely in details, but in fundamental principles of treatment, is the result of the new light which experimental pathology has thrown on the nature of disease-processes and on the factors concerned in their production in the skin as in other organs. . . . We now recognize the precise microbic agents which produce lupus, scrofuloderma, impetigo, leprosy or glanders. It is not only as primary causes, however, that the importance of the part played by micro-organisms in the genesis of skin diseases has come to be acknowledged, the effects of their activity as secondary causes are now seen to be still more far-reaching. . . . In the domain of practice the teachings of bacteriology have borne fruit in the extensive use of parasiticide agents. There is hardly a case of skin disease in which at some period or another of its course antiseptic and antiparasitic remedies are not indicated. The ideal antiseptic still remains to be discovered. I have so often found the latest products of the chemical laboratory fail to come up to the expectations that I had been led to form of them, that I can only conclude that the power of a substance to destroy or check the growth of micro-organisms in a test-tube is no measure of its therapeutic potency when applied to the human skin.

"It is not so much in the discovery of new remedies as in the improvement in the means and manner of applying those already known that progress has chiefly been made in recent years. . . . The intro-

¹ British Medical Journal, January 27th.

duction of superfatted soaps, and cleanly pastes and jellies has been of the greatest value. These methods of applying medicaments to the skin are as superior to those used by our predecessors of not many years ago, as the Henry Martini's and magazine guns of the present day are to the muskets with which Wellington's battles were won. I do not say that we are better men than those who have gone before us, but assuredly we are better armed.

"All this has led to a truer understanding of the insufficiency and folly of dietetic treatment of skin diseases and to a more intelligent control of the general medication. In the application of local treatment, for which we have better vehicles and better remedies, there are two essential conditions of success: first, the strength of the remedy must be carefully tempered to the disease; and, secondly, the application must be not only thorough but continuous."

Of massage, he says:

"Wherever there is effusion that cannot find an exit on the surface; wherever there is pain from pressure of imprisoned fluid or thickened tissues on the nerve ends; wherever there is stagnation of the blood stream, there massage is likely to be useful by its mechanical action on the parts to which it is applied. That, however, is the limit of its therapeutic virtue. . . .

"Almost the only distinct evidence of progress apart from local treatment to which I can point, is the fuller recognition which has been arrived at of the influence of the nervous system in the production of skin affections. . . . The knowledge of the intimate pathological connection between the nervous system and the skin gives the key to the successful treatment of many cases which defy all local measures."

AN ECCENTRIC RUSSIAN PHYSICIAN.

PROFESSOR ZAKHARIN, of Moscow, one of the physicians in attendance on the Emperor of Russia, and since the death of Dr. Botkin, the leading consultant in Russia, is renowned for his eccentricities as well as for his skill.¹

On entering a house he requires all the doors to be left wide open, all the clocks stopped, and dogs to be securely fastened away from his presence. He removes his over-garments gradually and never all in one place, his furs in one room, his over-shoes in the next, his gloves in a third, and so on. He insists on absolute silence on the part of the patient and the family, and will have no question answered save by "Yes," or "No." His dread of over-influence is almost a monomania; and his attention to detail is such that even in the simple cases he investigates the whole family history and social relations before directing treatment. His examination of the patient is sometimes three hours long—even in ordinary conditions.

One of his favorite theories is that of an idiopathic hypertrophy of the heart, upon which he has based a rule of living: "It is necessary to rest *before* getting tired." Accordingly he has the habit of sitting down every seven or eight steps.

Zakharin is now sixty-five years old, has been professor of clinical medicine at Moscow for thirty-five years, and is reported to have acquired over a million dollars.

¹ La Médecine Moderne, No 15, 1894.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 10, 1894, TO MARCH 16, 1894.

Leave of absence for six months, to take effect on or about May 1, 1894, with permission to go beyond the sea, is granted CAPTAIN WALTER W. R. FISHER, assistant surgeon, U. S. A.

By direction of the President, the retirement from active service, March 13, 1894, by operation of law, of MAJOR JOHN H. BARTHOLOMEW, surgeon, U. S. A., under the provisions of the act of Congress, approved June 30, 1882, is announced.

FIRST-LIEUT. PAUL F. STRAUSS, assistant surgeon, U. S. A., is relieved from duty at Fort Riley, Kansas, and ordered to report in person to the commanding officer, San Carlos, Arizona, for duty at that post, relieving FIRST-LIEUT. HARLAN E. McVAY, assistant surgeon, U. S. A.

FIRST-LIEUT. McVAY, on being relieved by FIRST-LIEUT. STRAUSS, will report in person to the commanding officer, Whipple Barracks, A. T., for duty at that post.

A board of officers to consist of LIEUT.-COL. CHARLES R. GREENLEAF, deputy surgeon-general; LIEUT.-COL. ALBERT HARTSUFF, deputy surgeon-general, U. S. A.; MAJOR BENJAMIN F. POPE, surgeon, is appointed to meet at the call of the president thereof, at San Francisco, Cal., for the examination of CAPTAIN WILLIAM R. HALL, assistant surgeon, with a view of determining his fitness for promotion, as contemplated by the acts of Congress approved October 1, 1890, and July 27, 1892.

CAPTAIN HALL will report in person to the president of the board for examination at such time as he may designate.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING MARCH 17, 1894.

L. W. SPRATLING, surgeon, ordered to the U. S. S. "Alert."

E. J. DEERE, surgeon, ordered to the U. S. S. "Raleigh."

E. M. SHIFF, assistant surgeon, ordered to the U. S. S. "Raleigh."

W. C. BRAISTED, passed assistant surgeon, ordered to hold himself in readiness for U. S. S. "Columbia."

G. E. H. HARMON, surgeon, from the U. S. S. "Yorktown" and three months' leave.

G. P. LUMSDEN, passed assistant surgeon, ordered to the U. S. S. "Yorktown."

APPOINTMENTS.

At the last regular meeting of the Board of Managers of the Massachusetts Charitable Eye and Ear Infirmary, DR. HENRY L. SHAW was elected as consulting surgeon; DR. FREDERICK E. CHENEY was elected as ophthalmic surgeon; DR. ALEXANDER QUACKENBOSCH was elected as assistant ophthalmic surgeon and DR. ALMON G. MORSE as ophthalmic house officer.

DR. PAUL THORNDIKE has been appointed surgeon to outpatients at the Boston City Hospital.

HARVARD MEDICAL SCHOOL.

EVENING LECTURES.

The next lecture will be given on Wednesday evening, March 28th, at 8 o'clock, by Dr. J. J. Putnam. Subject, "The Present Status of the Therapeutics of Nervous Diseases." Physicians are cordially invited.

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—A regular meeting of the Society will be held at the Medical Library, No. 19 Boylston Place, on Monday, March 26, 1894, at 8 o'clock, P. M.

Dr. E. H. Bradford: "Sprains and Disabled Joints." Discussion opened by Drs. W. M. Conant and R. W. Lovett.

Dr. A. Coolidge, Jr.: "Deviations of the Cartilaginous Septum." Discussion opened by Dr. J. W. Farlow.

JOHN T. BOWEN, M.D., Secretary.

NORFOLK DISTRICT MEDICAL SOCIETY.—The Brookline Fellows of the Norfolk District Medical Society cordially invite the Society to a Meeting for Scientific Improvement, to be held at the Town Hall, Brookline, on Tuesday, March 27, 1894, at 7.15 P. M.

Subject for discussion, TUBERCULOSIS. "The Natural History of the Tubercle Bacillus," S. A. Houghton, M.D. "Tuberculosis in Cattle, its Detection, Prevalence, etc.," F. H. Osgood, M.R.C.V.S. "The Treatment of Laryngeal Phthisis," S. W. Langmaid, M.D. "Tuberculosis in Mental Disease," W.

Channing, M.D. "Home Treatment of Phthisis," G. K. Sabine, M.D. "The Application of Climatic Therapeutics to Pulmonary Tuberculosis," E. O. Otis, M.D. Dr. F. C. Shattuck will open the discussion.

Lunch at 2.45 P. M.

J. C. D. Paxon, M.D., Secretary.

RECENT DEATHS.

DR. GIUSEPPE DAGNA, Emeritus Dean of the Medical Faculty of the University of Pavia, died February 3d.

SURGEON-COLONEL ARCHIBALD HAMILTON HILSON, M.D., C. I. E., late inspector-general of Civil Hospitals, Bengal, and one of the heroes of the Sepoy Revolt of 1857, died January 4th, aged fifty-nine years.

BOOKS AND PAMPHLETS RECEIVED.

Cases to Illustrate the Relationship which Exists between Wryneck and Congenital Hematoma of the Sterno-Mastoid Muscle. By D'Arcy Power, M.A., M.B., Oxon., F.R.C.S., Eng. Reprint. 1894.

Report of a Case of Cerebral Tumor, Diagnosed by Focal Symptoms, with Operation, Successful Removal of Tumor and Exhibition of Specimen. By D. A. K. Steele, M.D., Chicago. Reprint. 1894.

A Manual of Therapeutics. By A. A. Stevens, A.M., M.D., Lecturer on Terminology and Instructor in Physical Diagnosis in the University of Pennsylvania, etc. Philadelphia: W. B. Saunders. 1894.

The Relation of Peripheral Irritation to Disease; Considered from a Therapeutic Standpoint. Therapeutic Reflections; A Plea for Physiological Remedies. By Simon Baruch, M.D. Reprints. 1890-93.

Pain, Pleasure and Aesthetics, An Essay Concerning the Psychology of Pain and Pleasure, with Special Reference to Aesthetics. By Henry Rutgers Marshall, M.A. London and New York: Macmillan & Co. 1894.

Congenital Affections of the Heart. By George Carpenter, M.D., Lond., Member of the Royal College of Physicians; Senior Physician to Out-patients at the Evelina Hospital for Sick Children, London. London: John Bale & Sons.

Tables and Notes on Human Osteology, for the Use of Students of Medicine. By Sebastian J. Wimmer, M.A., M.D., with a preface by Prof. William F. Waugh, A.M., M.D. Philadelphia: The Medical Publishing Co. 1894.

Scarlatina and Scarlatinal Sore Throat; A Record of Milk Infection. By Arch. K. Chalmers, M.D., Ph.D., P.H. (Camb.), one of the Medical Officers of Health for the County of the City of Glasgow. Glasgow: Robert Anderson. 1894.

Excision of the Hip-Joint in Tubercular Disease. Circular-Saw Injury. The Early Removal of Tubercular Foci of the Bone. Primary Syphilis and Gonorrhoea in Children. By B. Merrill Ricketts, M.D., Cincinnati, O. Reprints. 1893.

Pigmentation of the Whole Surface of the Body, Occurring Suddenly during the Treatment of a Case of Psoriasis; Wart Growths upon the Palms and Soles following the Internal Use of Arsenic. By Albert E. Carrier, M.D., of Detroit. Reprint. 1894.

Modern Homoeopathy; Its Absurdities and Inconsistencies. By William W. Browning, A.B., LL.B., M.D., Brooklyn, N. Y., Lecturer Upon and Demonstrator of Anatomy, Long Island College Hospital, etc. Philadelphia: Press of Wm. F. Fell & Co. 1894.

Tumors, Innocent and Malignant, Their Clinical Features and Appropriate Treatment. By J. Bland Sutton, Assistant Surgeon to the Middlesex Hospital, London. With two hundred and fifty engravings and nine plates. Philadelphia: Lea Brothers & Co. 1893.

Hospital Dispensaries and Nursing; Papers and Discussions in the International Congress of Charities, Correction and Philanthropy, Section III, Chicago, June 12 to 17, 1893. Edited by John S. Billings, M.D., Henry Hurd, M.D. Baltimore: The Johns Hopkins Press. 1894.

Syllabus of the Obstetrical Lectures in the Medical Department of the University of Pennsylvania. By Richard C. Norris, A.M., M.D., Demonstrator of Obstetrics, University of Pennsylvania; Assistant Obstetrician, University Maternity, etc. Third edition. Philadelphia: W. B. Saunders. 1894.

A Practical Treatise on Medical Diagnosis for Students and Physicians. By John H. Musser, M.D., Assistant Professor of Clinical Medicine in the University of Pennsylvania, etc. Illustrated with one hundred and sixty-two wood-cuts and two colored plates. Philadelphia: Lea Brothers & Co. 1894.

Suicide and Insanity; A Physiological and Sociological Study. By S. A. K. Strahan, M.D., Barrister-at-Law; Fellow of the Royal Statistical Society; Member of the Medico-Psychological Association of Great Britain and Ireland; Member of the Medico-Legal Society of New York, etc. London: Swan, Sormenschein & Co. 1893.

Essentials of Physics, Arranged in the Form of Questions and Answers, Prepared especially for Students of Medicine. By Fred J. Brockway, M.D., Assistant Demonstrator of Anatomy at the College of Physicians and Surgeons, New York. Second edition, revised, with one hundred and fifty-five illustrations. Philadelphia: W. B. Saunders. 1894.

Medical Jurisprudence, Forensic Medicine and Toxicology. By E. A. Whitthaus, A.M., M.D., Professor of Chemistry, Physics and Hygiene in the University of the City of New York, etc., and Tracy C. Becker, A.B., LL.B., Counsellor-at-Law, Professor of Criminal Law and Medical Jurisprudence in the University of Buffalo. Vol. I. New York: William Wood & Co. 1894.

Total Extirpation of the Uterus; Cases Illustrating Various Indications for and Different Methods of Performing the Operation; Remarks upon Removal of the Uterus in Diseases of the Appendages. The Technique of Total Extirpation of the Fibromatous Uterus. The Operative Treatment of Complete Prolapsed Uteri et Vaginae. By George M. Edebohl, A.M., M.D. Reprints. 1892-93.

Poltz's Text-Book of the Diseases of the Ear and Adjacent Organs, for Students and Practitioners. Translated by Oscar Dodd, M.D., Assistant Surgeon at the Illinois Charitable Eye and Ear Infirmary, etc. Edited by Sir William Dalby, F.R.C.S., M.B., Cantab., Consulting Aural Surgeon to the St. George's Hospital. With three hundred and thirty original illustrations. Philadelphia: Lea Brothers & Co. London: Baillière, Tindall & Cox. 1894.

Syphilis in the Innocent (Syphilis Infantum), Clinically and Historically Considered with a Plan for the Legal Control of the Disease. By L. Duncan Bulkley, A.M., M.D., Physician to the New York Skin and Cancer Hospital; Consulting Physician to the New York Hospital, etc. The essay to which the College of Physicians of Philadelphia in 1891 awarded the Alvarenga Prize for the best Memoir on any medical subject. New York: Bailey & Fairchild. 1894.

An American Text-book of the Diseases of Children, Including Special Chapters on Essential Surgical Subjects; Diseases of the Eye, Ear, Nose and Throat; Diseases of the Skin; and on the Diet, Hygiene and General Management of Children. By American Teachers. Edited by Louis Starr, M.D., Physician to the Children's Hospital and Consulting Pediatricist to the Maternity Hospital, Philadelphia, etc., assisted by Thompson S. Westcott, M.D., Attending Physician to the Dispensary for Diseases of Children, Hospital of the University of Pennsylvania, etc. Philadelphia: W. B. Saunders. 1894.

Original Articles.

THE OPERATIVE TREATMENT OF UTERINE FIBROIDS.¹

BY E. W. CUSHING, M.D., BOSTON, MASS.

Of all the advances in surgery achieved during the last few years none has been more surprising or more gratifying than the improvement in the methods and in the results of the operative treatment of fibro-myomata of the uterus; while at the same time the more accurate knowledge of the clinical history and morbid degenerations of the neoplasma, which has recently been obtained, has introduced entirely new views as to the indications which call for operation and as to the dangers which are incurred by neglecting such growths until the life of the patient is actually endangered by their presence.

It is not very many years since, on the one hand, a uterine fibroid was regarded as a wholly benign growth almost sure to cease increasing, or to diminish, at the menopause; while, on the other hand, the results in the few cases subjected to operation were so unsatisfactory that there was but little encouragement for surgeons to persevere in attempting to remove these growths. Thus Mathews Duncan could say, "Whoever heard of any one dying of a fibroid tumor?" while physicians everywhere sharing his views created a body of professional sentiment which has come down to the present day, regarding such growth as comparatively innocuous, and strongly discouraging all operative interference, even in extraordinarily severe cases, until the life of the patient was in imminent danger. On the other hand, as good operators as Sir Spenser Wells, a man already distinguished in abdominal surgery and experienced in the removal of ovarian tumors, would entirely refuse to interfere with uterine fibroids; and if by chance one was disclosed on opening the abdomen for the removal of an ovarian tumor, far from proceeding with the removal of the growth, they would close the abdomen and in confusion lament the error of their diagnosis.

As the natural consequence of these views and conditions, hysterectomy was only performed as a last and desperate resort in patients who were sinking from hemorrhage, or from exhaustion incident to the growth or degeneration of the tumor. And it is little wonder that the mortality was high. The pioneer work in this operation was done in Massachusetts by those determined operators, Burnham and Kimball, of Lowell. Burnham's first operation was performed June 26, 1855, the patient being still alive in 1884. It is conceded that this was the first removal by abdominal section of the uterus and appendages for fibroid disease. Burnham operated 15 times with 12 deaths, a mortality of 80 per cent.; while his mortality in 338 cases of abdominal section of all kinds, including the hysterectomies, was 25 per cent., that from 238 complete ovariectomies being 20 per cent.²

By improvement of technique, and by the growth of institutions where a large number of cases could be operated upon under improved conditions by trained surgeons, the mortality from hysterectomy was gradually reduced from 80 per cent. to 60 and 50 per cent.

and finally to about 85 per cent., where it stood some ten years ago at the beginning of the era of advances in abdominal surgery. Since then the reduction of mortality has gone on progressively; but it is of the utmost importance to remember that the improved results are not all due to the improvement of surgery, but are due to the fact that the operation is now performed before the patients are so reduced as to have thrown away most of their chances of recovery.

Nevertheless, grim and lamentable cases still occur too often, where, either from timidity on the part of the patient, or oftener from bad advice and mistaken ideas on the part of her medical adviser, the time for favorable operation has passed by. The chances of recovery have been cruelly thrown away by miserable delay and worse than useless treatment, until the patient is delivered to the surgeon sinking under her burden, a subject for a hazardous and gruesome operation, and likely then to die, leaving grief to the friends, blame to the surgeon and discredit to the profession.

We are passing through the same change in theory and practice in regard to fibroid tumors which has already been accomplished in regard to ovarian growths. With the gradual enlightenment of the profession and of the public, it is now rare to find the formidable cases of huge neglected ovarian tumors which were formally so frequently brought to surgeons for operation. No one will now maintain, as was formerly done, that an ovarian cyst should not be removed until its presence actually threatens the life of the patient. Instead of throwing away the chances of the patient by delay, by treatment, by repeated tappings, all competent physicians now recommend removal of an ovarian cyst as soon as its presence is detected, with the result that the operation in these early cases has become practically free from mortality; it is approached with confidence; it is accomplished with facility; it is a grateful interlude between the serious acts of important abdominal surgery.

Now, in regard to uterine fibroids a similar course of reasoning will apply, *mutatis mutandis*; like ovarian tumors, they are apt to grow, and when of large size they are very likely to degenerate and to cause the death of the patient; unlike ovarian tumors, they are peculiarly apt to injure the health and exhaust the vitality of the patient by repeated and protracted hemorrhage, and they are liable to slough and to suppurate. In a considerable proportion of cases the myomatous uterus becomes affected with malignant disease. The tumor is liable to cause dangerous symptoms or fatal consequences by pressure on the ureters or on the intestine. If, therefore, there were any such certainty or probability of the continued growth of fibroid tumors that there is of the increase of ovarian tumors, the rules which are applicable to the latter class would at once govern our practice in regard to the former; the immediate removal of uterine fibroids as soon as discovered would be the rule. But here is precisely the difference between the two classes of tumors. Many women have fibroids which are small, which do not grow, and which cause no symptoms. In many others the tumor slowly increases during the years of functional activity of the uterus, but ceases to grow (or even diminishes) after the menopause. It is, therefore, obviously not necessary to operate on every tumor of this kind; and the establishment of the indications for surgical interference becomes in the highest a matter of individual judgment

¹ Read before the Obstetrical Section of the Suffolk District Medical Society, November 24, 1893.

² A full report of Burnham's 338 cases was published by his grandson, Dr. H. P. Perkins, Jr., in the *Annals of Gynecology*, May, 1888, vol. i, page 339.

and experience, to be determined by the nature of each separate case. Wherever there is a chance for difference of opinion, it is safe to assume that doctors, like other people, will disagree; but the more opinion can be founded on sound pathological knowledge and on the records of wide observation, and the more questions in dispute are illuminated by experience and elucidated by discussion, the nearer shall we approach to a consensus of opinion and to the establishment of definite rules of practice. In nothing is this more evident than in the treatment of fibroid tumors, and in no department of surgery is professional opinion crystallizing more rapidly into definite rules of procedure, based on accurate knowledge.

The latest aspects of this question are not as yet presented in the text-books, but are earnestly discussed in medical societies and medical journals in this and in other countries. Particularly, at the last two meetings of the American Gynecological Society and at the Pan-American Congress a great deal of attention was devoted to the subject of uterine fibroids; and while there are numerous individual differences of opinions, yet it is plain that those most interested in the subject, and whose opinion is based on the widest experience, have modified their views greatly within the last few years and are now approaching unanimity of opinion.

In the first place, it is practically conceded that electricity is powerless to prevent the growth of fibroid tumors; and it has been abandoned by many very competent men who, a few years ago, were adopting the new treatment with enthusiasm. It will, in many cases, arrest and control hæmorrhage; in many others it will allay pain and nervous symptoms; in not a few, however, it will set up very serious suppuration, or cause peritonitis of various grades, leaving adhesions which afterwards seriously complicate any operation which may become necessary.

It is substantially agreed that tumors, even of moderate size, require operation if they are growing, if they cause hæmorrhage, if they occasion pain or pressure symptoms, or if they are complicated by salpingitis. There is some difference of opinion as to the size which a tumor should have obtained to warrant removal. One would operate on growths as large as the fist, another on nothing smaller than a coconut, but none would countenance waiting until the tumor was larger than the adult head as was so frequently done only a few years ago, and as is still advised by some conservative, but ill-informed practitioners. It is agreed that the dangers of operation increase in direct proportion to the size of the tumor, the age of the patient, the reduction of vitality caused by repeated hæmorrhage and disturbance of the nutrition; that the fatal cases are usually the neglected ones; that the difficulties of operation and consequent dangers are enormously increased by the presence of adhesions, by the complications of salpingitis, of pyo-salpinx, or of cystic or purulent degeneration of the ovaries; that incarcerated tumors may press on the ureters and bladder, while large ones drag these organs out of place, often leading to serious and fatal disease of the kidneys; that a very large proportion of tumors commence to grow or continue to grow after the menopause; that even a larger proportion of those which, having arrived at large size at the time of the menopause, then cease to grow, do not diminish but degenerate, becoming soft and decomposed, and by slough-

ing or septic absorption lead to the death of the patient or to an operation *in extremis*. It is agreed that an operation for removal of an ordinary fibroid of the uterus by a competent surgeon upon a healthy patient is not much more dangerous, if at all, than is the removal of an ovarian cyst, and that all improvements of technique tend to reduce the danger of operative interference in uterine tumors to such an extent that they are more and more coming under the rules which are applied to ovarian tumors.

Another consideration is worthy of mention here, namely, that the diagnosis of pelvic growths is frequently so obscure; and the examinations on which it is based are even more frequently so insufficient that growths are often called fibroids which really belong to other and more dangerous categories. I have seen not a few cases where supposed fibroids of the uterus were really cases of cancer of the ovary, cancer of the uterus, solid ovarian tumor, pyo-salpinx with induration of the pelvic roof, impacted dermoid cysts, etc. Other surgeons have had similar experiences. The chances of operation have been lost or the results of surgical interference unduly jeopardized in these cases by well-meant delay based on the supposition that the growth was a fibroid of the uterus and therefore required no operation.

Having now noticed at some length the indications for operation in fibroids of the uterus, we may consider the different operations proposed for their relief or their removal. Those which have received any extended trial are:

- (1) Removal of the uterine appendages (Hegar, Tait).
- (2) Tying uterine arteries from vagina (Franklin Martin).
- (3) Myomectomy or removal of the tumor, leaving the uterus intact.
- (4) Removal of submucous fibroids through the os uteri and vagina.
- (5) Vaginal hysterectomy.
- (6) Supra-vaginal hysterectomy: *a*, stump fixed in abdominal wound; *b*, stump fixed just below abdominal wound, but outside of abdominal cavity (Kelly); *c*, stump turned forward into vagina (Byford); *d*, stump intra-peritoneal (Schroeder); *e*, modified by Martin, Zweifel, etc.; *f*, stump extra-intra-peritoneal, the arteries being tied in broad ligament and the stump covered by peritoneum (Eastman, Chrobak, Dudley, Goffe, Baer).
- (7) Total extirpation: a combined operation, tumor from above and cervix from below, with clamps below (M. D. Jones); with ligatures (A. Martin, Boldt). Total abdominal extirpation (A. Martin, L. Stimson, Krug, Polk and others).

The time at our disposal this evening will not suffice for the discussion of the technique of these various forms of operation; and probably such a treatment of the subject would not be of general interest. As may naturally be supposed, opinions are somewhat divided as to the choice of methods and as to certain details of operation and procedures which on the whole are essentially similar. Nevertheless, I believe it will be of interest to point out the indications which would govern me in selecting one method or another, omitting here historical details and questions to priority or invention.

(1) As to the removal of uterine appendages. This operation, introduced by Hegar and Tait, and resting

very largely on the authority of these names, and especially on the strong recommendation of Tait, gives excellent results in the case of small tumors where the principal difficulty is monthly hæmorrhage. Few operators, however, at present are willing to trust to it where the tumors are large and rapidly growing. It is hard to see how the artificial induction of the menopause will do more than the natural change of life; and this, as stated above, notoriously does not control the continual growth of tumors which are large and show a tendency to increase rapidly. Even Tait does not claim that it is of any use in cases of solitary soft myoma or in fibro-cystic tumors.

In the light of facts recently placed in evidence concerning Tait, his statistics have far less weight with the surgical world than was the case a year or two ago. The chief objections to this method, when the tumor is large, are, first, the possibility of degeneration of the growth, and, secondly, the difficulty of employing drainage. My own experience with this method has been very satisfactory. I have used it a good many times for small tumors, but only once for one larger than a coconut, which was firmly bound in the pelvis. This case died; and I have always been sorry that I did not perform a hysterectomy, inasmuch as I could not use drainage when the tumor was in the pelvis. In all the other cases menstruation ceased entirely, and the growth diminished or gave no further trouble. Other surgeons, however, report cases where the tumors continue to grow in spite of this operation, necessitating subsequent hysterectomy. The chief indication for the choice of this operation is the fact that the tumor is growing in the fold of the broad ligament, leaving the appendage readily accessible.

(2) As for tying the uterine arteries from the vagina hoping thereby to check the growth of the tumor, this is an operation recently suggested by Martin, of Chicago, but I have no personal experience of it. As the procedure is easy and safe, it seems not unphilosophical to try it in cases where the tumor is not so large that there would be danger of its degenerating or sloughing from the sudden cutting off of most of its blood-supply.

(3) Myomectomy, or removal of the tumor, leaving the uterus intact, may be a very simple or a very formidable operation, according to whether the growth is pediculated or is imbedded in the wall of the uterus and inclosed by a capsule consisting of uterine tissues. In the first case it is a safe and quick operation to constrict a pedicle and fasten it with pins in the angle of the abdominal wound. It is not so easy to treat the pedicle intra-peritoneally. As is the case in ovarian tumors, if the growth is cut away, the stump of the pedicle retracts, the vessels are hard to isolate and secure, the wound in the uterus gapes, and stitches used to close it are apt to bleed. The best method of intra-peritoneal treatment is to reflect the peritoneum from the pedicle, commencing at the lower part of the tumor, then to sew through the pedicle the shoemaker's stitch of catgut before cutting it, tightening and tying the ligature as the tumor is cut away, and covering the stump with reflected peritoneum.

The removal of large myomatous nodules from the uterus has been principally practised and recommended by Martin of Berlin, and is fully described in his work. It is not often that suitable cases occur for this operation, since usually the large nodule is accompanied by smaller ones; and where it does not seem that the pa-

tient will be cured by the removal of the uterine appendages, surgeons perform hysterectomy rather than to make and then close considerable cavities in tissues as retractile and vascular as are those of the uterus. The singular celerity and dexterity of Martin enables him to obtain results which are satisfactory, while those less gifted would not succeed as well.

(4) I shall say little concerning the removal of submucous fibroids through the os uteri. There is little new in this question, except that the ecraseur and the wire loop have fallen into innocuous desuetude, being replaced by simpler and more surgical methods of cutting and tying the pedicle, if there is any. While sublimate irrigation and packing with iodoform gauze have diminished the dangers of sepsis from cavities left in the uterine wall by the enucleation of submucous nodules, the difficult and hazardous operations which were formerly performed for the removal of large submucous growths have mostly been supplanted by hysterectomy. My experience would lead me to believe, however, that where a fibroid tumor of the uterus in the abdomen is complicated by the presence of a sloughing fibrous polyp which has been extruded from the uterus, it is the safest to remove the polyp first by vaginal operation, leaving the hysterectomy to be performed at a later date when the cavity of the uterus is free from infection.

(5) Vaginal hysterectomy offers an easy and safe way of treating cases where the uterus is of moderate size and where there is much hæmorrhage which is not easily relieved by curetting. It may also become an operation of necessity, when in attempting to remove a submucous growth, the uterus is perforated. Vaginal hysterectomy may fairly be considered as a rival of the removal of the appendages, as in suitable cases it is just as easy, is fully as safe, and because the uterus is of no use after the removal of the appendages, but may be very annoying to the patient, since it is heavy and is apt to become retroverted.

(6) A discussion of the various methods and modifications of supra-vaginal hysterectomy would alone form a voluminous paper. Of the two great varieties into which it is divided, the extra-peritoneal treatment of the stump by fixing it in the angle of the abdominal wound has been popular, and on the whole has given the best results of any method devised. Keith, Bantock, Tait, in England, and in this country Price and his followers, use a wire loop to constrict the pedicle, which is tightened by a small ecraseur or *serre-nœud*. The Continental operators, and some in this country, prefer the use of an India-rubber constrictor made of an ordinary piece of tubing; and if this is properly used, it is in my judgment far superior to the wire loop. The principal point to be observed is that it should pass twice around the pedicle, above one pin and below the other; in this way it can be made to lie on the skin instead of being buried in the wound. If the pedicle is properly made, it is slender; by exposure to the air it becomes entirely dry, does not slough nor smell badly, and when properly adjusted the dressings need not be touched at all until about the tenth day, when the constrictor and the stump are removed together. The other points to be observed are infinite care in cleansing the vesico-uterine fold of the peritoneum, the accurate coaptation of the abdominal peritoneum around the stump and below the constrictor, and the use of the glass drainage-tube in all complicated cases. The tube should be separated from the stump by two

or three stitches, that is, by an interval of about three-quarters of an inch, and can be removed as usual on the second day without interfering at all with the stump. With these precautions the objections to this treatment, which have been the principal cause of the introduction of other methods, are not well founded. There is no need of having a bulky pedicle or a sloughing stump or a large opening predisposing to hernia. Contrary to the general opinion on the subject, it requires a higher degree of real surgical skill, care and perfection of technique to treat the pedicle in this way properly than to remove the uterus entirely; but the saving of time, of shock, of hæmorrhage and exposure of the intestines, which can be obtained by this method, must weigh strongly in its favor as against the more recent methods of operation which have lately come in fashion and which are considered more ideal. The method has served me well in all sorts of difficult cases—in big tumors, in adherent tumors and in tumors complicated by pyo-salpinx, and even where there was perforation of the intestine; and I know that in feeling that it should not be abandoned lightly in favor of other methods, I have the full support of Bantock, of Price, and of many other operators, whose excellent results entitle their opinions to the utmost consideration.

In spite of the good results obtained by the extra-peritoneal method of treating the stump, some operators have always insisted that this was not the best procedure that could be devised, but that like the corresponding treatment of the pedicle in ovariectomy, it was merely a temporary method and a halting-place in the march of progress towards an ideal method. First, Schröder, and then Martin, of Berlin, were the great maintainers of this theory; and their method, as is well known, consisted in making the stump with an anterior and posterior flap which were brought together by silk or catgut sutures. Unfortunately, owing to the treacherous nature of uterine tissue, the stumps would slough if tied too tightly, while if tied less firmly they would ooze or bleed; so that the results would not compare with less ideal but more practical methods. Zweifel has now so modified this method by an interlocking stitch of silk in the broad ligament and of catgut across the cervix, that he has obtained admirable results; while Martin has abandoned it in favor of total abdominal extirpation. The intra-peritoneal method of Schröder has, however, also been modified in this country in such a manner that the uterine arteries are tied in the broad ligament outside (but near) the uterus, when the cervix is cut away low down, and is then either dilated, burned or drained after the method of Eastman, which has been followed by Chrobak and others on the Continent, or is simply left untouched according to the method of Baer; in either case the peritoneum is united above the stump. The only difficulty with this operation is that there is a tendency to suppuration below the peritoneum; and if much of the stump is left, it is very apt to slough, owing to the entire deprivation of nutrition of the part. This not unnaturally leads to the conclusion, that where the uterine arteries were so securely ligated as to make the stump liable to slough, it was best to remove it *in toto*; and this method has been adopted with great enthusiasm by Martin in Germany, and by L. Stimson, Krug, Polk, Boldt, Edebohl and others in this country. As one step in arriving at this operation, the body of the uterus was removed from above and the cervix from

below, as in vaginal hysterectomy, but with the introduction of the Trendelenberg posture it is so easy to remove the whole from above, that it is now usually done in that way. Martin attaches the vagina to the peritoneum all around with catgut sutures, the ends of all of which are brought out through the vagina. Stimson and Polk use simply four sutures, one each in front and behind and one on each side, the ends of these are brought out from the vagina and the space between is occupied with a packing of iodoform gauze. Polk and Mann strongly recommend the additional use of a glass drainage-tube in the abdominal wound. Other operators close the vagina with catgut and unite the peritoneum above it with a sero-serous continuous catgut suture. Many consider a glass drainage-tube desirable in all these cases, although not all consider it essential.

This, then, at last would seem to be the ideal operation for the removal of fibroids, the only objections being the time required and the resultant shock. The abdomen is widely open for from one to two hours, according to the dexterity of the operator and the character of the case; this is a very serious consideration, and without desiring to depreciate the march of progress toward the ideal, I will say that this operation is not one for beginners, but for dexterous, experienced and skilled surgeons.

A *résumé* of my experience may prove interesting. From January 1, 1890, to November, 1893, I performed hysterectomy for fibroid tumors of the uterus 33 times at the Charity Club Hospital; and from June 25, 1892, to November 1, 1893, I performed the same operation 14 times in my private sanitarium, and three times in private houses, making a total of 50 cases, of which I have accurate records, with 10 deaths, or 20 per cent. Of these cases there were: extra-peritoneal stump, 29, with 4 deaths, or 13.7 per cent.; extra-intra-peritoneal stump, 18, with 4 deaths, 22.2 per cent.; abdominal total extirpation, 3, with 2 deaths, or 66.6 per cent. Besides these, I have had one case of vaginal hysterectomy for fibroids, which recovered; two cases where the operation was primarily to remove large, sloughing, fibroid tumors which had been extruded through the uterus, and in which it seemed at the time best to remove also the body of the uterus from which the growth originated, and which was the seat of other myomatous nodules. Both of these cases died: one on the second day, from uræmia caused by long pressure of the tumor on the ureters and secondary disease of the kidneys; the other sank on the third day after operation, without rise of temperature, dying apparently from cardiac failure due to repeated hæmorrhages, septic absorption before the operation, and the shock of the delivery of the tumor, which, when I first saw the patient, was hanging between her thighs, larger than a child's head, and extremely offensive. During the same period I have removed the uterine appendages some ten times for small uterine fibroids, often combining the operation with ventro-fixation of the uterus. All of these cases recovered, except one who died of chronic sepsis four weeks after the operation. Besides these cases I have had a number of ordinary fibroid polyps, which were removed without difficulty; but I have not taken the trouble to look up the exact number.

Now, in considering the results obtained by the different methods of operation, it is necessary to examine the causes of death in those cases of each class which

ended fatally, in order to discover which operation offers the best chance of recovery, and which is best adapted for any particular class of cases. And first, as to the four deaths which occurred in 29 cases where the stump was treated extra-peritoneally. Three of these occurred at the Charity Club Hospital, and two came close together, and were accompanied by three other deaths from sepsis following particularly simple operations. I think that all these deaths were due to the poisoning of the house by one of the cases of sloughing fibroid above referred to, although they occurred some time after the death of that patient; it seemed impossible to get good results, and I was compelled for a time to suspend abdominal work in that place. It was on the presentation of these facts to the management of the Charity Club that it was decided to build a new building adapted to the serious work which had to be performed there. I am happy to say that the new hospital gives such facilities as can never be obtained in an old dwelling-house used as a hospital, and that there is but little danger of an occurrence of an epidemic of sepsis within its walls. This leaves two deaths to be accounted for among the 29 cases where the stump was treated extra-peritoneally; of these, one occurred at the Charity Club Hospital after the removal of a very large tumor from a woman considerably passed the menopause. The other case was at my sanitarium, in a patient who had a large myoma complicated by pregnancy, requiring a Porro operation; in each case the death was due to obstruction of the bowels. The occurrence of these two deaths set me to reflecting on Keith's remarks concerning the tension of the broad ligament which is occasioned by the traction of the stump when treated extra-peritoneally, and led me to try the intra-extra-peritoneal treatment which was so warmly advocated by Eastman, Chrobak, Baer and others.

Eighteen cases treated by the latter method gave four deaths, or a mortality of 22.2 per cent.; these deaths all came near together, and were particularly painful to me because three of them occurred in patients where there were no particular complications, where the tumors were not inordinately large, and where the operation could have been performed by the extra-peritoneal method with excellent prospects of success.

These four deaths occurred after a series of 13 consecutive recoveries by the intra-extra-peritoneal method, and just when I was flattering myself that I could remove fibroids without fatal results. Besides the cases that died, one other had a considerable discharge of pus from the vagina, no doubt coming from the cervix uteri. The study of these cases revealed one important point in all of the first ten, that is, in nearly all of those who recovered, so much of the uterus was removed that very little of the cervix was left; this was widely dilated, the canal thoroughly burned with the thermo-cautery, and occupied by a twist of iodoform gauze providing free drainage for the space left below the peritoneum and leaving very little of the cervical tissue to be nourished indirectly by anastomosis. In all of the cases that died the dilating and burning of the cervix was omitted; and although gauze was drawn through the undilated cervix from above downward, it is probable that drainage was not sufficient. Probably, too much cervical tissue was left to be properly nourished after the ligation of the uterine arteries. We are thus met with the same difficulty as in Schröder's operation where a cervical stump is left; if the blood-

supply is entirely checked, it sloughs, otherwise it bleeds. One of these cases was of a nature that probably could not have been saved as the tumor had degenerated; the patient was some fifty-four years old, and she had suffered from a series of very severe chills, fever and profuse sweats at intervals of two or three days for three months before she came into my hands. Her physician, Dr. Thurlow, had recognized the nature of the trouble and insisted on the necessity of operation, but the patient obstinately maintained that she had chills and fever, and would not consent to surgical interference until she was evidently failing. The tumor was removed without accident, but the patient showed symptoms of shock while on the table, and did badly from the first. She had a severe chill and sweat the day after the operation, had almost complete suppression of the urine, and died on the fourth day. The tumor weighed over seventeen pounds, and contained over a quart of pus and much broken-down tissue. At the autopsy there was a little purulent-looking fluid on the stump; no signs of general peritonitis. There was multiple abscess in one of the kidneys. Neither of the ureters had been included by the ligatures. Leaving this case out of consideration, I have ten cases of the Eastman-Chrobak operation where the cervical stump was short and was dilated, burned and drained; all of these recovered. There were six cases which were meant to be done by Baer's method, without dilating or burning the stump; and three of these died, besides the hopeless case above reported.

The results of the latter cases, which occurred last summer, lead me to try total abdominal extirpation, in order to get rid of the stump entirely, as advised by so many advanced operators of the day; although I have tried this three times, and lost two cases, yet here again the studies of the causes of the deaths show how misleading are percentages which give only the mortality, without describing the cases.

The first patient had cardiac disease, with compensatory hypertrophy of the heart. She had a large fibroid, which was growing rapidly in a young woman under thirty years of age, and occasioned very profuse and exhausting hæmorrhages, leaving the patient in a deplorable state. She entered the Charity Club Hospital last summer, and insisted on operation in such a way that I could not refuse it, although the extra risk was pointed out to her. The tumor rose high in the abdomen and was freely movable, and it seemed probable that it could be removed in a few minutes with extra-peritoneal treatment of the stump. On opening the abdomen, however, it was found that the tumor had lifted up the broad ligament on each side, and that to make a stump it must be widely separated from its investment of peritoneum. When this was done, the stump was so small that it was a very little matter to remove it entirely. The patient, however, did not react well. She suffered no pain whatever, but was ominously quiet, with a slightly subnormal temperature, and died on the third night, her temperature rising that very evening.

The next case was an ordinary one and recovered without any trouble whatever.

The last case was in a middle-aged woman who had carried a small fibroid tumor for several years, and until past the menopause; during the seven months preceding operation, it had begun to grow very rapidly, so that the specimen, which I showed at the last meet-

ing of the Suffolk District Society, weighed some twenty-five pounds. The tumor was firmly adherent to the abdominal wall and to the omentum, obtaining nourishment chiefly from the latter through a multitude of vessels of which the veins were dilated and looked like bunches of earth-worms. The ovaries were cystic, and with the tubes were firmly bound down to the pelvis. From the rapid growth I feared that the tumor was sarcomatous, and thought the safest way was to remove all. The patient never rallied well from the long operation, never got fairly warm in her hands and feet, although everything possible was done for her; and she died septic on the third day.

The conclusions of my own experience briefly summed up are as follows:

(1) That electricity is useless and dangerous, and has no place in the armamentarium of the surgeon.

(2) That no method will compare with that of extra-peritoneal treatment of the stump in favorable cases, that is, where the abdominal walls are not too thick and the tumor can be lifted out so that a constrictor can be applied around the whole pedicle, including the uterine appendages; that the advantages of this method lie in its rapidity, in the short time during which the abdomen is open, in the entire protection of the intestines from exposure and from handling, and in absence of shock; that with proper care there need be no sloughing of the stump, and little or no suppuration of the wound. I show here two stumps, each removed on the tenth day, with the ligature still in position; they are perfectly dry, hard and inoffensive. This, then, for me is the operation of election for the present, especially in private practice and in all cases where patient is not strong and is ill prepared to withstand the shock of the longer operation required by other methods of treatment of the stump.

(3) For the intra-extra-peritoneal treatment, I should always in future leave as little of the cervix as possible, dilate it, burn it and drain it. This method is applicable to cases in which it is difficult to apply the former one, owing to thickness of the abdominal walls or the rigidity of the pelvic floor, or the presence of dense adhesions requiring drainage. I see little advantage to be gained from leaving any cervix. To avoid the great danger of sloughing of the stump, it must be amputated well below the level of the internal os, after separation of the bladder from the cervix and ligation of the uterine arteries. When all this has been done, there is no difficulty or loss of time in removing all the uterine tissues. Drainage should usually be employed, both through the vagina by gauze and by a glass tube at the bottom of the pelvis, as there is pretty sure to be free oozing.

The fact remains, however, and must never be forgotten, that for either of these methods of operation, by intra-extra-peritoneal treatment or by total abdominal extirpation, the operation is prolonged from half an hour to an hour. During this time the pelvis is exposed to the air and to much handling; considerable blood may be lost, which runs in among the intestines; there is an added shock from the large amount of ether consumed; and the whole burden of proof is, in my judgment, still on those who would use these operations in cases in which the extra-peritoneal treatment can easily and quickly be performed.

ACCORDING to Dr. Squibb, American chloroform is on the whole purer than that used in Europe.

TWELVE CONSECUTIVE AND SUCCESSFUL OPERATIONS FOR APPENDICITIS.

BY JOHN W. KEEFE, M.D., PROVIDENCE, R. I.,
Visiting Surgeon to St. Joseph's Hospital, Surgeon to Out-Patients at
the Rhode Island Hospital.

(Concluded from No. 12, page 284.)

CASE VII. M. O'G., male. Age thirty, weaver. First case operated upon in Rhode Island between the attacks.

Admitted to St. Joseph's Hospital May 7, 1893. Family history good. No evidence of transmitted disease; good moral habits. He has since infancy been delicate, although he has had no serious illness until August, when he was taken with pain while at work; pains at first general abdominal, later becoming localized in the right iliac region. He has had attacks since, on an average, every two weeks. Some attacks lasted ten days, while others but one or two days. He was obliged to remain from work so often that he finally had to give up his position in the factory. He had a cyanosed and anxious expression of countenance, weak pulse and poor general appearance. There was pain on deep pressure over McBurney's point.

May 9th. Patient's abdomen made aseptic previous night, and bowels evacuated. Ether breakfast.

Operation. Patient etherized. Present, Drs. Collins, Day, Mitchell, Noyes, Black, Mahoney, Barry and O'Neil. Abdomen scrubbed again with soap and water, ether and corrosive-sublimate solution. Sterilized towels about the field of operation. Instruments sterilized by steam. An incision three inches long was made, a little to the right of and parallel with the border of the rectus muscle, through the abdominal wall. After considerable search the appendix was found, very much enlarged and bound down by firm adhesions to the inner and posterior aspect of the cæcum. Following the longitudinal muscular fibres of the cæcum materially aided in finding the base of the appendix. The adhesions were so firm that I removed three-quarters of an inch of the appendix, thinking that was all there was left of it; but with the finger I was able to break up the adhesions between the appendix and cæcum, disclosing one and one-half inches of appendix still remaining. A catgut ligature was tied around the base of the appendix, and allowed to remain; the appendix was severed with scissors, and a Paquelin cautery used to sear the end of the stump. While searching for the appendix several mesenteric glands were noticed having the appearance of tubercular infiltration. All of the coats of the appendix were thickened. The abdominal cavity was flushed with boiled water and spoused dry. A catgut continuous suture was used to approximate the peritoneum, and four silver-wire sutures through the entire abdominal wall. Silkworm-gut sutures through skin completed the operation. An iodoform dressing was applied. Patient made a good recovery from the operation. Patient rested well during the night. Treatment consisted in giving a drachm of hot water every fifteen minutes.

May 10th. Temperature, morning, 101°, pulse 103; evening, 102.5°, pulse 104. No nausea. Patient of a nervous temperament, discontented, and worries a great deal. He has a cough, with slight expectoration.

May 11th. Temperature, A. M., 101°; P. M., 102°. Peptonized milk, one drachm every fifteen minutes. Pulse strong.

May 13th. Patient slept but little, exceedingly nervous and fretful.

May 15th. Bowels evacuated by rectal injection of a few drachms of warm glycerine.

May 17th. Temperature normal at noon. Coughs a great deal, and expectorates considerable thick mucus.

May 18th. Dressings removed for first time since the operation. Union perfect. No tympanites or pain on pressure, as before operation. The four silver-wire sutures were removed. Another aseptic dressing applied. Diarrhœa in afternoon, controlled by bismuth and opium.

May 23d. Silkworm-gut sutures removed. Firm union present. Flexible collodion painted on wound, and an abdominal binder applied. Forcible pressure in the right iliac region now gives no pain, and all symptoms which he complained of before the operation have disappeared.

May 25th. Temperature, *p. m.*, 103°. Delirious at night. General weakness.

May 28th. Examination of chest shows dulness at both apices and increase in vocal resonance. Sputum examined, and found to contain tubercle bacilli.

May 31st. Diarrhœa. Temperature 103.5°, pulse 130. Patient takes considerable nourishment.

June 5th. Still weak, cough and expectoration. Appetite improving.

June 6th. Discharged at own request.

September 6th. Patient has improved a great deal. Is able to go about out-of-doors, but still has a cough, and expectorates a thick, yellowish mucus. Has had no trouble, since the operation, in the right iliac region.

CASE VIII. E. M., male. Age seven and one-half years.

This boy I saw in consultation with Dr. Payan on the ninth day of last August. He gave a history of having injured his right side while playing with another boy some weeks previously. Dr. Payan saw him for the first time August 2d, when his temperature was 103°, pulse 120. Pain referred to right knee.

August 3d. Pain in right lumbar region.

August 8th. Temperature and pulse elevated. Slight nausea last few days. No vomiting at any time. Bowels regular. Chills and sweats for last four days. Dulness over right lumbar region, and sense of resistance. Dr. Payan introduced a needle, but did not detect pus. Poultices locally and anodynes.

August 10th. At 10 *a. m.*, the boy was restless and hypersensitive. Temperature 100°, pulse 110. Anxious expression. Right thigh flexed. On inspection of abdomen, a fulness was seen in right loin. Sense of resistance. Pain and dulness on percussion over this prominence. Pressure over McBurney's point produced pain, which was referred to right loin. Operation advised.

At 4.30 *p. m.* an operation was performed. Dr. Payan etherized the patient, and I made an incision, one inch above and parallel with the crest of the ileum, two inches long, cutting through the skin, muscles, fascia and peritoneum, into an abscess cavity which extended from the region of the right kidney to the iliac fossa. Intestines formed the inner wall of the abscess cavity. The appendix was not found. About six ounces of very fetid pus escaped. A second opening was made in the right iliac region by cutting down upon a

finger introduced into the abscess cavity through the original wound, and a rubber drainage-tube passed through both openings. The cavity was sponged out with a solution of corrosive sublimate (1 to 2,000), and an antiseptic dressing applied. The patient's recovery has been uneventful; the wounds are entirely healed.

September 6th. Boy attends school; no trouble from wound.

CASE IX. W. S., male. Age forty-two, grocer.

Admitted to St. Joseph's Hospital August 13, 1893. Father died of phthisis; he, however, was the only one of his family to have the disease. Mother's family noted for longevity. Until within two years patient was an exceptionally healthy man, weighing 200 pounds. He has gradually failed, until at the present time his weight is only 130 pounds. Last January patient had a severe intestinal hæmorrhage, the cause of which was diagnosed by his attending physician as duodenal ulcer. He then gained in health and strength until two weeks ago, when he was seized with severe pain in the right iliac region. Four days later he could feel a swelling in same location. Pain on walking or stooping or pressing over swelling. A surgeon was called, who accompanied him to Boston, where an eminent surgeon of that city was consulted. A second consultation of surgeons from Providence and Boston was held at patient's home on August 11th, and an unfavorable prognosis given the patient's family. No operation advised.

August 14th. I saw patient for the first time. Temperature 100°, pulse weak; sweats; anxious countenance. Inspection showed slight prominence in right iliac region. Circumscribed area of dulness, with sense of resistance about five inches in diameter just below and to the right of the umbilicus. No fluctuation could be detected. Diagnosis, appendicitis with circumscribed intra-peritoneal abscess. Operation advised.

August 15th. Operation. Present, Drs. Collins, McCusker, O'Neil and Barry. Patient etherized. Field of operation rendered aseptic. An incision about three inches in length was made over the most prominent portion of the tumor, and parallel with the median line, through the abdominal wall, and into an abscess cavity walled off by firm adhesions to the parietal peritoneum. About six ounces of greenish pus was evacuated. The abscess was irrigated with a corrosive-sublimate solution (1 to 10,000), and two silkworm-gut sutures introduced to close the angles of the wound. A rubber drainage-tube was passed into the abscess cavity, and an iodoform dressing applied. Patient rallied well from the operation. Warm peptonized milk and whiskey given in small doses. At night patient complained of abdominal pain, unrelieved by morphia. An enema of soap-suds and turpentine produced a discharge of fecal matter and a large quantity of gas with great relief.

August 16th. More abdominal pain, relieved by enema. Wound dressed, considerable discharge. Evening temperature 100°, pulse 120.

August 17th. Patient's general condition improved. Drainage-tube removed. Temperature normal.

August 19th. Patient sleeps and takes nourishment well. Diet: milk, egg-nog and beef-tea. Wound looking well. Slight discharge.

August 24th. Wound dressed every second day. Sutures removed.

August 27th. Edges of wound brought in apposition with strips of adhesive plaster.

August 29th. Notwithstanding the patient has strict orders not to leave his bed, he went out twice to the closet.

September 2d. Two silkworm-gut sutures were introduced to bring granulating edges of the wound in apposition, and antiseptic dressing applied.

September 4th. Wound nearly healed. Area of dulness has disappeared, with the exception of a slight amount of dulness in close proximity to the incision. Patient eats, sleeps and looks well. Says he feels as well as he ever did in his life.

October 1st. Patient has gained in weight. No pain in right iliac region.

CASE X. D. C., male. Age fourteen years, messenger boy.

Patient has been strong and robust until the present illness. He is an exceptionally well-developed boy. On August 13, 1893, after playing base-ball, he was seized with pain in the right side of the abdomen. On the following day the pain increased, and he was obliged to remain in bed. The family physician was called. Diagnosed the disease as appendicitis, and ordered anodynes and ice applied locally. He obtained considerable relief, and the case looked like one that would terminate by resolution. I saw the patient for the first time August 21st. His temperature was 100°, pulse 130. Abdomen distended and tympanitic on percussion, except just above the crest of the right ileum where there was an area of dulness three inches in diameter, and tenderness on pressure. Deep pressure over McBurney's point produced pain in area of dulness. The boy's general appearance was poor, and his anxious expression denoted serious trouble.

August 22d. Boy admitted to St. Joseph's Hospital. No marked change in symptoms.

August 23d. Tympanites has disappeared. Temperature 100°, pulse 98. Area of dulness, and pain on pressure above crest of right ileum. No sense of resistance. No fluctuation; mass could be detected on palpation. Assisted by Drs. Day, O'Neil and Barry, I operated by making an incision three inches long in the right lumbar region, commencing just above highest point of the crest of the right ileum and continuing toward the ribs; the incision being parallel with the median line. The several layers of the abdominal wall, namely, integument, superficial and deep fascia, the external and internal oblique muscles, transversalis muscle and transversalis fascia, subserous areolar tissue and peritoneum, were all readily recognized and divided with the knife. There was no cedematous condition of these tissues, such as is commonly found in this disease. Owing to the thickness of the abdominal wall, fluctuation could not be detected, even when the peritoneum was reached. About five ounces of greenish and fetid pus was evacuated. Coils of intestine could readily be felt forming the inner wall of the abscess cavity. Appendix was not found. The cavity extended from the lower border of the right kidney to the cæcum. The abscess cavity was irrigated with boiled water, a rubber drainage-tube inserted, and an iodoform dressing applied.

August 24th. Patient slept well last night. Warm peptonized milk in small doses. Wound dressed. Considerable discharge in dressing.

August 25th. Dressed. Tube cleansed, reinserted. Enema produced copious evacuation from bowels.

August 27th. Diet, milk and gruel. Wound dressed every day. Discharge is decreasing and cavity becoming smaller.

August 31st. Tube removed. Wound looks well.

September 6th. Patient eats and sleeps well. General appearance good. Wound gradually closing.

October 1st. Wound entirely healed.

January 1, 1894. Patient in good health. No return of disease.

CASE XI. A. C., male. Twenty years of age, single, carpenter.

Admitted to St. Joseph's Hospital September 9, 1893. Good family history. Three years ago patient had an attack of diarrhoea and vomiting, with severe abdominal pain, most intense in the right iliac region. He recovered in a few days, and has had two attacks since, the last occurring last summer. His temperature then ranged from 100° to 102°. Pain severe, localized in right iliac region. Vomiting and constipation were also accompanying symptoms. His temperature on admission to the hospital was 99°, and he complained of pain on firm pressure over McBurney's point. No mass or sense of resistance could be felt. Removal of appendix advised.

September 13th. Operation, under ether. Asepsis aimed at in preparations. An incision three inches in length was made, parallel with the median line, the centre of the incision being over McBurney's point. The abdominal cavity was opened, and the appendix was found bound down by slight adhesions behind and to the left of the cæcum. It was three-quarters of an inch thick and two and one-half inches in length. Coats thickened. The appendix was excised about three-sixteenths of an inch from the cæcum. The mucous and muscular layers of the stump were drawn outwards, and a ligature of fine sterilized silk placed about them. The peritoneal coat of the appendix was now drawn over the ligatured mucous and muscular coats, and united by three fine silk, Lembert sutures. Four silver-wire sutures through abdominal walls, and several silkworm-gut sutures through skin and superficial muscles closed the abdominal wound. No drainage. An aseptic dressing applied. Patient had a comfortable night. Scarcely any pain. He took only drachm doses of hot water every fifteen minutes during the first twenty-four hours.

September 14th. Drachm doses of peptonized milk, alternated with hot water. No nausea at any time.

September 18th. Bowels moved for the first time since the operation by an enema.

September 22d. Silver-wire sutures removed. Primary union.

September 26th. Silkworm-gut sutures removed. Discharged from the hospital cured.

December 20th. Patient in good health.

CASE XII. E. H., male. Aged twenty-seven years, horse-car driver.

Admitted to St. Joseph's Hospital October 16, 1893. Patient's family history is good. Until one year ago he was in good health; then he was seized with severe abdominal pain, more intense on the right side, accompanied by fever. In a few days he was better, but occasionally had pain in the right iliac region, but not severe enough to prevent him from attending to his work. Last March he had a similar attack to the first seizure. Ten days ago he had more severe pain than in previous attacks, with pain localized in right iliac region. Vomiting and rise in temperature. He was

treated by ice locally and opium internally, until these symptoms subsided so that he was able to walk about for past few days. He has pain on complete extension of thigh, and greatest tenderness on pressure just below and to the right of McBurney's point. There is a small area of dulness and a sense of resistance over the same region.

October 17th. Operation, under ether, with strict asepsis. An incision three inches long, parallel with the median line, was made over the area of dulness. The various abdominal layers were incised until the peritoneum was reached, when it was found that the cæcum was adherent to the abdominal wall below the site of the incision. The wound was enlarged upwards until the abdominal cavity could be opened above the point of adhesion of cæcum to the abdominal parietes. By careful manipulation the adhesions, which were on all sides of the cæcum, were severed by the fingers, and the appendix was found by following the longitudinal fibres of the cæcum. The appendix was bound to the cæcum throughout its entire length. Its coats were thickened, and near the junction of the appendix and cæcum its cavity was obliterated and its walls gangrenous. A silk ligature was passed around the stump of the appendix and tied. Owing to the inflammatory process which had occurred, the peritoneal coat of the appendix could not be united over the remaining stump; neither could a fold of the adjacent peritoneum covering the cæcum be employed to cover the stump of the appendix, as the coating of lymph so thickened the peritoneum that it was not readily pliable. The abdominal wound was closed with thirteen silkworm-gut sutures, and an aseptic dressing applied. A drachm of hot water was given every fifteen minutes during the next twenty-four hours.

October 18th. Pain relieved by sulphate of morphia (gr. $\frac{1}{2}$), hypodermatically given. No nausea. One drachm of peptonized milk every half-hour. Patient feeling well.

October 24th. Bowels moved by enema. Temperature normal. Sleeps well. Takes plenty of milk.

October 27th. Seven of the sutures removed.

October 30th. Six other sutures removed. Highest temperature since operation 99.5°, which was on the third day. Wound has healed by primary union.

December 15th. Patient in good health.

None of the cases reported have had recurrence of the disease. Two cases developed small hernia at the seat of the cicatrix. My observations lead me to say that while some of the cases require a very simple operation, others call into action all the skill and ingenuity of an expert. I am convinced that the aspirator may be very harmful, and should never be used in cases of appendicitis. Early operation, that is, within the first forty-eight hours, by a skilful surgeon, will save the greatest number of lives.

ALUMINUM FOR SURGICAL INSTRUMENTS.—A physician who got rid of some of his steel instruments and bought others made of aluminum, says that he is sorry that he changed. The aluminum probes, sounds, tongue-depressors, and that sort of thing do not oxidize, to be sure, but he finds that they are deficient in elasticity and stay bent after pressure. He declares, moreover, that he likes to feel that he has a hold on something when he uses an instrument, and aluminum is so light that he can put no trust in it.

PATHOLOGY OF DIABETES MELLITUS.*

BY ELLIOTT P. JOSLIN A.B., PH.D.

DIABETES mellitus is now considered by many authors to be a disease of more than one type and in this paper the classification of Lancereaux¹ will be adopted. He divides the disease into three forms, (1) constitutional, (2) nervous and (3) pancreatic. The symptomatology, pathology and experimental work which has been lately done on these varieties of diabetes will be here discussed, and an account of Chauveau's recent work given.

(1) The constitutional or fatty diabetes is the common form of this disease, and is well known to you all. It is most apt to occur in middle life, and frequently comes on in successive generations of a family, and cases are on record where it has been traced through four generations. Schmidt² has traced heredity in 248 out of 600 cases of diabetes, and probably they were mostly of this variety. Obesity and gout are often precursors; and headache, epistaxis, hæmorrhoids and neuralgia are frequently prodromal symptoms. The disease begins insidiously, slowly advances, and often is accidentally discovered or brought to light by some of its characteristic complications. When discovered it rapidly yields to dietetic treatment, and after a residence at some resort like Carlsbad, the sugar may wholly disappear from the urine. It will return, however, in time, and the treatment must constantly be kept up. In these persons, the urine seldom rises above three or four litres per day, and the amount of sugar varies between 90 g. and 300 g. for the greater part of the time. This form of diabetes may have a long duration, and not greatly interfere with a man's business. Cases have lasted thirty and forty years.³ Death comes either from an intercurrent disease or from the complications.

Unfortunately the pathology of this disease is not understood, and later investigations may destroy this classification.

Experimental work has added little to our knowledge of this type of diabetes. Considerable work, however, has been done on the so-called alimentary, toxic and phloridzine glycosurias, which will now be described.

Normal urine contains a small quantity of dextrose.⁴ Experiments have been made on men and dogs to whom large amounts of sugar have been given. When 250 g. of cane-sugar were given to a man⁵ who had been previously kept on a nitrogenous diet, 0.7 per cent. of the amount appeared in the urine. In dogs⁶ the ingestion of such an enormous quantity as 500 g. caused 3 per cent. of the amount to appear. Eleven individuals⁶ underwent a rather agreeable experiment in which they partook of a supper of sweets, ices and champagne. Two to four hours later the urine of five of the party contained from 0.1 per cent. to 0.25 per cent. of sugar. Two hours later the sugar had disappeared. Another writer⁷ has found that animals which had been starved for a few days, when given small amounts of sugar experienced a transitory glycosuria. A similar lack of assimilation of sugar may explain light forms of diabetes. This is known as alimentary glycosuria.

Toxic glycosuria is due to the ingestion of various poisons, notably curare. A host of investigators have

* Read before the Boylston Medical Society of the Harvard Medical School, November 17, 1893.

found sugar in the urine after injections of curare; but an equally large number have affirmed that glycosuria was absent, providing artificial respiration was maintained. Halliburton⁷ says that the glycosuria is not present in these cases, but that the sugar reaction is due to glycuronic acid. He furthermore adds that this explains the supposed glycosuria which sometimes follows the use of morphia and chloroform. Strychnia, nitrate of uranium and many other drugs are claimed to have the power of bringing about a temporary glycosuria.

Phloridzine glycosuria has excited much interest. When phloridzine is given to an animal in the food, or subcutaneously, a glycosuria is produced. It commences about three hours after the ingestion of the glucoside, attains a maximum in twenty hours, and ceases within a day and a half. The glycosuria varies with the amount of food ingested. Various explanations of this phenomenon have been offered, but a recent series of experiments by Minkowski and von Mering throw much light on the subject. In birds glycosuria does not follow extirpation of the pancreas, but von Mering⁸ found on giving phloridzine that sugar appeared in their urine. Dogs, rendered diabetic, passed an additional amount of sugar when they were given the drug. This led Minkowski to make the following experiment.⁹ He removed the kidneys, both from a healthy dog and from a dog suffering with diabetes produced by pancreatic extirpation. To the healthy dog he gave phloridzine. After a time the blood of both animals was examined. The diabetic animal's blood contained 0.3 per cent. to 0.5 per cent. of sugar, which is from two to three times the normal quantity, while the phloridzine animal showed an abnormally small amount of sugar in the blood. He argues that if sugar is being formed in the organism, removal of the kidneys, thus preventing its excretion, will cause a storing up of it in the blood. The experiment shows that in the diabetic animal this was done, while in the phloridzine animal the sugar, far from being increased, was diminished. He, therefore, concludes that the glycosuria produced by phloridzine is due to its direct action on the kidneys.

In considering this constitutional type of diabetes, with regard to which we know so little, it is well to remember that an excessive amount of carbohydrates and some poisons may cause a temporary glycosuria, and that the kidneys under certain circumstances may allow the passage of sugar.

(2) The nervous or traumatic¹ variety of diabetes is the mildest of the three forms. It comes on after shock to the nervous system caused either by trauma or some severe mental strain, for example, worry, anxiety and the like, and runs a variable course. Polyphagia is absent, and the patient is seldom troubled with polydipsia. The urine is perhaps twice the normal amount, and though sugar is present, it is not in large quantities. There is little loss of weight. Subjected to treatment, hygienic and dietetic, the individual rapidly recovers, and the transitory glycosuria is over. Complications are rare. There is a sure tendency to recovery, and death almost never occurs unless there are extensive lesions of the central nervous system.

Pathology. — The pathology of the nervous form of diabetes has been earnestly studied and with good reason, for clinically mental disturbance appears to play a great rôle in its etiology. Packard⁹ says many railroad engineers are victims to this disease. Paige¹⁰

lays great stress on mental emotions. Madigan¹¹ has observed glycosuria alternating with insanity in a patient. Savage¹² has found diabetes and insanity alternating in families. Nagel¹³ has observed two cases of persistent glycosuria following an apoplectic attack. Dr. R. H. Fitz¹⁴ referred to the presence of glycosuria in epilepsy. Windle¹⁵ has tabulated the records of 184 brain examinations in the post-mortems of diabetic persons. In 91 instances, the brain was normal; and of the remaining 93, 23 were connected with the fourth ventricle. These lesions were of the most varying type; cerebral hæmorrhage, meningitis, tumors and congestion of the blood-vessels were all noted.

The whole subject was looked into by a committee of the London¹⁶ Pathological Society in 1882, who reported that they failed to find in the brain "any change which could be regarded as exclusively or constantly associated with diabetes."

In 58 cases of diabetes in which an examination of the spinal cord was made, 37 were found normal; and in the remainder there was no characteristic lesion.¹⁶

Experimental Work. — The experimental work of Claude Bernard, on the production of glycosuria by the puncture of the fourth ventricle, was one of his most brilliant achievements. This has been repeated many times with success. If the medulla be punctured in the region of the vaso-motor centre of a well-fed animal, sugar will appear in the urine in considerable quantity. After a few hours the sugar will have reached a maximum, and in a day or two, or even less, the sugar will be absent from the urine. If the animal has been starved previous to the experiment, little or no sugar appears. It would thus seem likely that the lesion to the fourth ventricle in some way acted on the liver so that the change of glycogen into sugar was accelerated, and the blood thus loaded with sugar emptied its excess into the urine.

The pneumogastric nerves¹⁷ run to the liver, via the solar and hepatic plexuses. Section of these nerves does not give rise to glycosuria, nor does stimulation of the peripheral end of the section. This shows that the impulse from the diabetic centre in the medulla does not travel along these nerves. On the other hand, electrical stimulation of the central end of the section produced a glycosuria analogous to that brought about by puncture of the medulla. Furthermore, it is claimed that in some cases an irritation of the branches of the tenth pair of cranial nerves in the abdomen, liver, lungs, heart, stomach and intestines may in some cases bring about a temporary appearance of sugar in the urine. This would imply that the pneumogastric exercises an inhibitory influence upon the diabetic centre of the medulla.

The liver receives another nerve-supply through the splanchnics. When these nerves are cut, no sugar appears in the urine; and if then the diabetic puncture is made, it fails. Evidently, the action of the diabetic centre on the liver is by means of the splanchnic nerves. These have been traced to the spinal cord, with more or less probability, through the gangliated cord of the sympathetic, the first dorsal ganglion, the annulus of Vieussens and the lower cervical ganglion. Probably they do not leave the cord always at the same level.

Lustig obtained a transitory glycosuria by making lesions of the solar plexus, and Lepine has produced diabetes by electrization of the nerves of the pancreas.

"Section and subsequent stimulation of the central end of the sciatic nerve causes diabetes."¹⁸

With regard to these experiments on the nervous system, I should like to call your attention to the following considerations: (1) the glycosuria has been transitory in every case; (2) the experiments are severe, and might of themselves produce such a constitutional derangement that glycosuria would result, even if there was no injury to the nerves; (3) as for an injury of the solar plexus producing glycosuria, Minkowski has shown this view to be erroneous. The work of Chauveau on nerve lesions is so recent that it will be deferred to the end of the paper.

(3) The pancreatic or thin type of diabetes is the most severe form of diabetes mellitus. In one class of cases, an individual who has been in perfect health is plunged into the midst of a severe diabetes. In other cases the symptoms come on gradually; and belching of wind, nausea, a sense of fullness and weight in the epigastrium are often the first indications of trouble. Diarrhoea is often present. In still other cases, what is supposed to be a fatty diabetes develops into the thin variety.¹⁹ When the disease is established the polyphagia, polydipsia and polyuria are extreme. The skin is harsh, dry and leathery to the touch. Emaciation quickly comes on, and there is great fatigue on exertion. The knee-reflex is usually abolished. Often the hair is lost, and the patient's teeth decay or fall out. The mental character is changed, and the unhappy individual is often in a state of mental depression. Hectic fever has been observed. The evolution of the case is characterized by its rapidity, and in the course of a period from a few months to three or four years, the patient usually succumbs to phthisis or diabetic coma. The urinary symptoms are much more severe than in either the fatty or the nervous forms. The quantity ranges between three and ten litres, and is generally between five and seven. The urea is decidedly increased and the sugar excreted per day is from 300 g. to 500 g.

Pathology.—Thomas Cowley,²⁰ in 1788, was the first to record a lesion of the pancreas in connection with diabetes mellitus. He observed an atrophy of the gland, with the presence of calculi, and suggested that it might be the cause of the disease. During intervals of forty years, more or less, Chopart²⁰ and Recklinghausen²⁰ made similar observations. But it was not until 1877 and the few following years, that the matter received much attention. Lancereaux¹ then published his two cases. In one of these the pancreas was atrophied, and much of the glandular structure was lost; in the other it was only with difficulty that the gland was found at all; but when found, calculi were discovered in the canal. Lancereaux's memoir led pathologists to study the pancreas more carefully; and, as a result, in quite a number of instances of diabetes, pancreatic lesions have been found. There would undoubtedly to-day be more recorded cases of changes in the pancreas in diabetes, were it not for the fact that the gland may look perfectly normal to the naked eye and yet on microscopical examination show marked alterations.^{20 21} Until this becomes more generally known, a diseased pancreas will be often overlooked.

What is the character of these changes? They are most varied, but the predominating characteristic is an increase in the amount of interstitial tissue. Williamson²⁰ has collected 100 cases from the literature upon

the subject; 47 showed an atrophy more or less marked, and of this number the gland was almost absent in three; in two others it was not recognized by the naked eye, and in two there was a cystic dilatation of the duct. Seventeen out of 100 were in a condition of marked fatty degeneration; and in some instances an increase of the connective-tissue, the presence of calculi or atrophy were coexistent with the main lesion. In another group of 13, the gland was transformed into a firm mass of fibrous tissue; in three of this number the lesion is stated as a marked cirrhosis. Of the remaining cases eight were cancer, six were cysts and three abscesses. There were two cases of "pancreatitis and pancreatitis hæmorrhagica," and one each of calcified, cirrhotic and cystic pancreas, while in the remaining case the occurrence of calculi was alone stated. Rokitsansky¹⁹ found the pancreas affected in 13 out of 30 cases. Saundby²¹ gives seven cases in which the pancreas was atrophied and four where it was abnormally firm and fibroid. Windle¹⁵ collected post-mortem records on the pancreas in 139 cases. In 65 of the number, the gland was normal. Lest some of his cases and those of Williamson may be identical, I will pass them by, simply stating that atrophy and fatty degeneration were the most common affections.

Are these changes in the pancreas which are found in diabetes accidental? Are they the result of the disease? Do they furnish the cause of one form of this malady?

The first question can be answered in the negative with a good deal of assurance. Pancreatic changes have been found too often in connection with diabetes to be accidental. It does not seem likely either, that they are the result of the disease. They are too diversified to have a common origin. That they are concerned intimately with the production of diabetes, their frequency and the experimental work done on the pancreas makes highly probable.

(To be continued.)

Clinical Department.

THROMBOSIS OF THE CENTRAL ARTERY OF THE RETINA, WITH UNUSUAL FEATURES.¹

BY EDWIN E. JACK, M.D.,

Ophthalmic Surgeon to Out-Patients, Boston City Hospital; Assistant Ophthalmic Surgeon, Massachusetts Charitable Eye and Ear Infirmary.

THE patient was a small and rather thin woman, forty-three years of age, who had always had fair health, and had never had any previous trouble with the eyes. On July 25, 1893, she was seized with sudden and severe pain through the left eye. The pain was confined to the eye, and was sharp and cutting in character. On the night of the 28th, the pain, still of the same kind and situation, became excessively severe, and the sight of the eye was suddenly lost. Coincident with this the conjunctiva became injected and the eye "looked swollen" — this increasing in the next few days. For about six weeks previous to this time the patient had had attacks of sudden blindness in the left eye, possibly three a week, coming on at irregular intervals and lasting from ten minutes to two hours.

I first saw her July 30th, and at that time she was much exhausted by the terrible pain and the entire loss of sleep for three nights. The condition of the eye was as follows. Conjunctiva injected and quite cedematous, raised in a mound partly around the cornea. V=0. Media clear. Whole fundus, except at periphery, an almost milky white, more intense around the macula. Macular region, for a space about one-third the size of disc, a pale red approaching a slaty color and sharply defined. Nerve head white except at porus, where it was pinkish; outlines obliterated. On lower temporal side a fair-sized hemorrhage, near this other very small hemorrhages. All vessels small. Some began at porus without blood-contents, but as they approached the periphery were partially filled with a granular-looking blood-column, giving the vessel an uneven appearance of local contractions and dilatations. Other vessels began at the porus with blood-contents of the same granular appearance, and as they approached the periphery lost their contents and appeared as white cords. These cords, however, were interrupted in places with small cylinders of blood — this happening mostly at the junction of branches. At every heart-beat there was a to-and-fro movement of the broken blood-column in both arteries and veins — toward the periphery in the arteries and toward the disc in the veins; but no progress was made, the blood returning to its original position. Some of the vessels with blood-contents had white borders; and two small vessels branching from the disc toward the macula were visible only as white, thread-like lines.

The appearance of the fundus August 2d was about the same, except that the macular region was a slaty-

brown color and no movement of the blood-column was visible. There was less injection and cedema of the conjunctiva. On August 4th there had been but little pain since the last visit. The region around the eye, especially the brow and nose, was tender. No cedema of the conjunctiva and very little injection. Fundus-nerve very pale, but outlines very little obscured. Some cedema of retina remaining, but general color of eye-ground pink. Macular region, for a space rather larger than the disc, mottled much as in chorio-retinitis.

The last observation was on January 25th of this year, just six months after the attack. Externally nothing abnormal. Fundus in general of normal color. Disc atrophic. Vessels about the same as previously described, but with more signs of perivasculitis. Macular region mottled, and around it spots, mostly small, of a pale-yellow color. Toward the periphery, especially between the vessel branches, there were appearances very like those seen in retinitis proliferans, but with no elevation, these patches merging into others having the characteristic appearance of disturbed retinal pigment. The eye was still absolutely blind.

Fourteen months ago the patient gave birth to a child after an easy labor. Seventeen years before this her only other child was born. About ten days after her last confinement she complained of a prickling and sleepy sensation in the right arm, which under bathing and massage disappeared. Three months later she began to have trouble in using the arm and hand, and soon they were practically useless. At present she can raise the elbow but little; the arm is fixed in a partially flexed position; the fingers also are partially flexed and have but little movement.

The present health of the woman is good. Within a year she has felt hardly as well as usual, but there have been no definite symptoms except dyspepsia. There have never been any signs pointing to cardiac or renal disturbance, and she has never had rheumatism. There is no history, and there are no signs of syphilis or of vascular degeneration. An examination of the urine at her last visit showed — color pale, specific gravity 1.012, no albumen, no sugar. The heart has been examined recently by her physician, Dr. E. S. Jack of Melrose, and is wholly normal.

There are in this case, it seems to me, several unusual and interesting features. The excessive pain and the conjunctival cedema are certainly unique and hard to explain. As far as the attacks of blindness and the fundus appearances are concerned there are several possibilities. These are embolism and thrombosis of the central artery and thrombosis of the central vein.

The case certainly has the typical appearance of embolism, with more than usual cedema. This supposition, however, does not well explain the many attacks of transitory blindness. The aura which occasionally precedes embolism, taking place in about one-fourth of the recorded cases, is, I think, rarely so frequent or complete. Schuabel and Sachs have explained these attacks by the theory that partial emboli shift their position at times, eventually becoming permanently fixed and entirely blocking the blood-current. Another explanation is that a partial embolus may cause a spasm of the vessels, thus shutting off the blood-current, this passing off and allowing the blood to circulate again.

Thrombosis of the central vein was first noted by

¹ Read before the New England Ophthalmological Society, February 6, 1894.

Loring, and corroborated later, anatomically, by Angeliucci. Its distinguishing feature in all grades is a great distention of the veins, and there is usually no diminution in the size of the arteries. In the severe cases there is a strong resemblance to hæmorrhagic retinitis, with large and tortuous veins. In our present case there were a few small hæmorrhages, but they certainly occur to a limited extent in embolism. There was no venous distention—an important negative point. With this exception the case resembles one of Loring's examples of venous thrombosis, especially as regards the extensive œdema of the retina. In his patient, who had aortic obstruction, he considered that the attacks of transient blindness which had come on at intervals for many years, were the effect of temporarily weakened heart-action on an eye with abnormal vessels. The absence of physical or other signs of heart-trouble in the present instance does not eliminate the possibility of an embolus starting from that source; but it does, it seems to me, destroy the application of such a theory in accounting for the repeated attacks.

Finally, there is arterial thrombosis, a condition which, according to Loring, Priestly Smith and others, is probably more frequent than supposed. Indeed, they consider that many of the specimens called emboli are really thrombi. The fundus changes are the same as in embolus. Previous attacks of transient blindness in the affected eye and even in the fellow eye, from probable spasm of the vessels, are given as a distinguishing feature of this condition. This corresponds more easily to the facts in the present instance than either of the other alternatives. The presence of the moving blood-columns, showing in all probability an incomplete shutting off of the current, does not aid in establishing this diagnosis, as the same phenomenon undoubtedly occurs in embolism. Unfortunately, too, the existence of perivasculitis of the retinal vessels so early cannot be taken as a sign of any analogous process further back, for the same thing can come on in the very earliest stages of embolism, where there is not any question of vascular trouble in the central artery.

It is interesting to look at the matter from another point of view—the possible connection in etiology between the monoplegia and the process in the eye. The monoplegia, judging from the nature of the paralysis, was cerebral, and it would seem most probable that it was of thrombotic origin. The existence of signs of vessel degeneration would throw much light on the question of a common pathology; their absence leaves room for doubt. Whether the blood state soon after the confinement may have had any influence in causing the monoplegia and in creating a condition of the heart or large vessels from which later an embolus could have come, is a question of importance. I will go no further than to say that, if we admit any connection at all, such a sequence seems probable.

From this standpoint, then, we come to no conclusion more definite than before. Clinically the case resembles one of thrombosis of the artery more than anything else. This diagnosis, too, explains best a pathological connection between the monoplegia and the blindness. For these reasons, and because there seems to be a growing opinion that thrombosis rather than embolism is the more usual process, I have retained that title. The conjunctival œdema may have come from an involvement of other vessels. I know of no explanation for the pain.

Medical Progress.

RECENT PROGRESS IN LEGAL MEDICINE.

BY F. W. DRAPER, M.D.

MEDICAL EXPERT TESTIMONY.

MEDICAL expert testimony has inexhaustible interest as a reform topic. The uses and abuses of this kind of proof continue to engage the earnest attention of medico-legal writers. As in the case of some of those chronic ailments of the human race so familiar to medical practitioners as clinical opprobria, the number of remedies suggested attests the difficulty of the treatment; so in the present instance, every year calls out a new panacea for a disorder about the diagnosis of which there is substantial unanimity among physicians. One of the latest suggestions relative to the employment of experts comes from Dr. L. C. Gray, of New York, and evidently had its source in a very extensive personal experience in court proceedings.¹ Dr. Gray's remedy takes a double form: (1) the selection of medical men by the presiding judge to sit on the bench with him in an advisory capacity in trials which do not need juries; and (2) a conference of all the medical men in cases tried by a jury. The former plan has its analogy in the use of assessors in the English admiralty courts. The latter method, in the author's opinion, would bring about substantial agreement among the medical witnesses with reference to facts and objective conditions, although conclusions therefrom, diagnostic and prognostic, might differ. To the objection that the system of medical assessors and medical conferences here urged is opposed to the principles of our law, Dr. Gray courageously answers that if that be so, "the principles of our law are radically faulty"; and again, "a law that ceases to be the embodiment of common-sense has outlived its usefulness and ought to be superseded."

WOUNDS WITHOUT INJURY TO OVERLYING CLOTHING.

Examples of the improbable serve to check the medico-legal sin of dogmatism. The following are illustrations of what must be considered an unusual combination of conditions.

Dr. Spokes, of London,² reports the case of a man who, while leading a horse, stumbled and fell; the animal trod on him in such a way as to make a wound of the scrotum out of which the right testicle was extruded so that it lay outside its normal covering. The man's explanation of the wound was that the horse's hoof forced against the scrotum the metal edge of a purse which was carried in the pocket in such a position that it lay close to the genitals. The clothing, including the fabric of the pocket, was entirely intact. The edges of the wound were clean-cut.

Dr. Wagner, of St. Louis,³ found in the foregoing a reminder of an experience of his own having similar features. While on a hunting trip through thick woods, Dr. Wagner carried a small hatchet in his belt for the purpose of cutting away a passage through the underbrush. In following game down a rather steep hill, he tripped and fell quite heavily, driving the blade of the hatchet against his thigh. He felt some pain, but as his clothing showed no external sign of a cut or

¹ New York Medical Journal, May 20, 1893.

³ New York Medical Journal, March 11, 1893.

tear, he attributed his sensation to a simple bruise, until he felt the blood within his underclothing and on undressing found a cut three-quarters of an inch long in the front of his thigh. The cut was somewhat irregular and left a scar as broad as it was long. The clothing showed no sign of injury whatever.

THE DIAPHANOUS TEST AS A PROOF OF DEATH.

The term "diaphanous test" has been applied to an observation which consists in raising the hand of a supposed dead person, placing it before a strong artificial light, with the fingers extended and just touching each other and looking through the narrow spaces between the apposed fingers to see if a scarlet line or edge persists; the theory being that the presence of such a tint indicates that circulation of the blood continues and that there is evidence of life. This test received the approval of the French Academy of Medicine.

Edwin Haward presents a case which shows that the test should not be relied on alone as a conclusive one; the case also demonstrates the difficulty occasionally encountered in distinguishing real from apparent death, and the need, in such cases, of applying all the reliable methods for the prevention of deplorable haste, awaiting if need be the advent of decomposition if other appearances and conditions are in the least equivocal.⁴ A woman of seventy-three, a subject of chronic bronchitis, was found early one morning in bed, insensible and apparently dead; but she looked so like-life, although not breathing, that her family had great doubt if death had actually occurred and Dr. Haward was summoned to solve the doubt. He found on his arrival, half an hour later, entire absence of respiration, of pulse and of heart-beat; the hands, slightly flexed, were rather rigid. These signs afforded a strong presumption that the woman was dead; but her countenance looked like that of a living person. This fact and the fact that once previously she had passed into a death-like state, with similar symptoms, even to the rigidity of the arms and hands, from which state she had recovered, caused the medical attendant to apply all known reliable tests and to call in expert help for the purpose. Sir Benjamin Ward Richardson was the consultant and his observations on the body of the woman were made with unusual care. Ten tests were applied, of which eight gave affirmative results in conformity with death; but there were two which were equivocal. Blood drawn from a vein in the arm was very dark, but flowed out in a fluid state and did not coagulate when exposed to the air. But the diaphanous test was the more striking; when the hand, with the fingers brought near together, was held before a strong light, there was a distinct red line of coloration between the fingers, as is seen in the healthy living hand. The body was allowed to remain in a warm room until the final proof, that of decomposition, removed every possible doubt. Dr. Richardson observes⁵ that the lesson to be learned from this case is that the diaphanous test is of itself "positively worthless." He has seen an ordinary case of simple syncope in which there was entire absence of the rosy tint between the fingers, although the patient quickly recovered consciousness.

MEDICO-LEGAL RELATIONS OF CRANIAL INJURIES.

The head is, of all regions of the body, a part whose lesions present the greatest gravity, and are the most

often fatal; it is particularly exposed to contusion injuries which represent weapons of the most primitive kind, and which offer the most frequent examples of homicidal violence. Maissiat,⁶ of Lyons, has made a comprehensive study of these injuries of the skull. He calls attention first to the difficulties met in determining the kind of weapon with which a given scalp-wound has been made; a blow with a blunt instrument may make a wound upon the head resembling an incised or punctured wound. In these cases the use of a lens is a valuable aid; it discovers irregularities of the edges and deeper parts not apparent otherwise. Scalp-wounds tend to take on a rectilinear appearance in consequence of the retraction of both the pericranium and the outer tissues of the scalp where the parts are divided; this tendency is more marked in the scalp than in any other part. Another important medico-legal point is brought out by the author: there may be fracture of the skull without any lesion of the external soft parts or any external suggestion of traumatism.

For medico-legal purposes, cranial fractures are studied by Maissiat according to the method of their production: (1) by puncture; (2) by a cutting weapon; (3) by contusion; (4) by a fall from a height. In fractures of the first group, the lesions are limited to the point struck; if the weapon is of medium size, there are no radiating fissures in the bone, and even if the weapon is of considerable size, the stellate radiations are not extensive. Fractures by a cutting weapon (sabre, hatchet) show most often a clean section of the bone, with fissures extended in the axis of the principal lesion, with few fragments, and with only an exceptional extension of the break into the base of the cranium. Blows with a club cause a more or less comminuted fracture, with radiations extending from the chief lesion, and offering no uniform rule of extension; if the weapon used has a broad striking surface, the bony lesion which results is more apt to penetrate to the base of the skull, thus resembling the effects of a fall. In these latter cases, unless the fall is very considerable, the comminution is not extensive; in any case, it is very common to find the fissure or fissures projected from the vertex to the base, especially into the anterior fossæ. Experiments by Perin have shown that these indirect lesions of the base of the skull are rarely the result of any injury other than a fall; that they do not readily follow a blow with a club, however heavy the blow may be.

PHENOMENA AFTER DECAPITATION.

Laborde has reported some instructive observations upon the head and body of a man executed by decapitation.⁷ In two-and-a-half minutes after the axe of the guillotine fell the oculo-palpebral reflex failed to respond. The patellar reflex continued to the end of the third minute. The persistence of the reflexes through even this short interval proves, at least, that decapitation does not cause immediate and absolute inhibition. The cardiac impulse continued eleven and a half minutes. The cadaver presented the penis in a state of erection, without a discharge of any kind. The right frontal lobe of the brain was uncovered by trephining, the operation being begun twelve minutes after the decapitation; after exposing the motor convolutions, an electric current was passed for stimula-

tion of the gray matter. Very clearly defined movements of the right facial muscles resulted. Laborde's explanation of the appearance of the muscular contractions on the right side, rather than on the left, is that the electric current was diffused.

DEATH BY HANGING.

In the course of some investigations into the pathology of subserous hæmorrhages in asphyxia, Corin instituted a series of experiments on the blood-pressure and the nervous phenomena in death by hanging.* Repeating with some modifications the observations of Fredericq, Konow and Steenbech, he established the important part which compression of the carotids and pneumogastric nerves has in the course of death by hanging, and demonstrated the secondary or negative importance of occlusion of the jugular veins. With regard to the pneumogastrics, Corin found that pressure on those nerves, whether they were isolated or not, resulted in a slowing of the respiration and a coincident quickening of the heart-beats. There is no questioning of the truth of Coutagne's theory that compression of the vagi abridges the duration of the asphyxia in hanging.

With regard to compression of the carotids, experiments by injection prove the complete occlusion of those arteries when the body is suspended by the neck, and such being the case, there must necessarily be a marked degree of cerebral anæmia to aid in the fatal issue, for the vertebrals are too small and tortuous to maintain the supply of arterial blood.

DEATH BY STRANGULATION.

Strangulation as a method of suicide is so rare that the following instance is of interest.* This case was the subject of an inquest at Hastings, England, the deceased being a middle-aged female servant. Her dead body was found in a room whose windows and doors were locked on the inside; it was lying on the floor, face down, with the hands beneath the chest. There was no appearance of struggling. Blood oozed from the mouth, and the tip of the tongue protruded. Around the neck were two yards of list, and, over this, three yards of tape; neither of the ligatures was knotted, but was simply wound about the throat, below the cricoid, evenly, layer on layer. The only clothing was a night-dress, and alongside the body, on the floor, was a blanket. A little blood was found on the pillow of the bed in the woman's bedroom, and the surgeon who made the autopsy testified that, in his belief, the strangling was begun in this room, and was completed in the room where the body was found. The woman was a strong, muscular person; her motive for self-murder was not determined, although there was some evidence that she had been a subject of religious mania. The post-mortem appearances were those of asphyxia.

THE DOWNING PROFESSOR OF MEDICINE.—The Downing Professorship of Medicine in the University of Cambridge, England, which was left vacant by the retirement of Dr. Latham after a service of twenty years, has been filled by the election of Dr. J. Buckley Bradbury of Cambridge.

Reports of Societies.

OBSTETRICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

O. H. WASHBURN, M.D., SECRETARY.

MEETING of November 24, 1893.

DR. E. W. CUSHING read a paper on

THE OPERATIVE TREATMENT OF UTERINE FIBROIDS.¹

DR. JOHN HOMANS: I am glad to hear this full and honest report from Dr. Cushing, giving the results in all his cases, whether good or bad. This is the only way we can arrive at any conclusions as to the advisability of operations or methods of operating.

In these cases of fibroid tumors wisdom is shown in choosing the cases that ought to be operated on, and in letting alone those that will do well unmeddled with. I have seen about 600 cases, and have operated upon about eighty. I presume that some of the 520 I ought to have operated on, and that in some of them my diagnosis was wrong; but I have tried to choose wisely. I always ask women on whom I do not operate to come and see me again in six months, or sooner, so that I may keep track of the tumor. I have watched a number of women, and have seen tumors diminish and disappear, and others increase in size; and I have operated on a tumor whose growth I had watched for thirteen years. I must say that I operate more frequently now than I did five years ago. I have operated nineteen times during these past ten months. Sometimes the shock of the operation in removing a large tumor full of blood is severe. I have had one lately where the tumor was not simply red in color, it was scarlet; and the removal of the tumor with other hæmorrhage caused a fatal result from shock twelve hours after operation. Very much blood was taken away with the tumor.

Fibroid uteri occasionally become cancerous. I have seen this happen in an old calcified fibroid which I saw at an ovariectomy in a woman of seventy. She died of cancer of the uterus four years after ovariectomy. This would be an argument in favor of operating on fibroids. Sometimes the blood-supply of fibroids will be cut off without apparent cause, and they will slough. I removed one about a month ago which filled the uterine wall symmetrically and was about nine inches by six inches in size. It was brown, and would have caused the patient's death in a few weeks or months. I did not suspect the condition before operating. Although the pedicle was treated intra-peritoneally, the patient left the hospital at the end of three weeks, having had no rise of temperature.

Fibroids may become filled with dilated lymph-spaces, and these spaces may become the seats of hæmorrhages of quite an extensive character. Both of these last two conditions would warrant removal. Adhesions in fibroids are very rare, but sometimes one meets with quite serious posterior ones, causing much hæmorrhage if they are attached to the mesentery, as I have once seen them. Some tumors grow very large slowly, and some diminish in size without apparent cause. If you only see these cases once you cannot tell which will grow and which will remain stationary or retrograde; but if you can watch them, you may be able to decide wisely.

I have had to operate once during pregnancy. I

¹ See page 301 of the Journal.

had advised against marriage on account of the fibroid; but my advice was not heeded, and pregnancy followed. A practitioner who was called thought the case was one of ovarian tumor; and as there seemed some doubt about the character of the tumor, I got Dr. Mixer to draw out a little disk of the growth. This little operation caused intense pain, so that at least a grain of morphia was injected in the course of about an hour, I think. The next day the patient was insane, and became more and more violent; the temperature rose; and I operated to save her life. I was able to remove the tumor without opening the uterine cavity, or removing the ovaries. The stump was treated extra-peritoneally. About ten days afterwards abortion took place, and sanity gradually returned. A little blood comes out of the scar at the menstrual periods.

I have removed some very large tumors and some very small ones. The largest was fifty-two pounds in weight, and the smallest a few ounces. Electricity à la Apostoli is useful in relieving pain and in checking hæmorrhage; but it does not diminish the size of the tumor, as a rule, unless the menopause occurs during or soon after the treatment.

In regard to the treatment by removing the ovaries, I operated by this method several years ago. One tumor as large as a large orange disappeared in four weeks, and none has ever grown since, during a period of ten years. In another case the uterine hæmorrhage continued; and two years after removal of the ovaries, I removed a large pediculated fibroid through the vagina, so that the loss of the ovaries was unnecessary. Two other cases were unaffected when I last heard from them.

The method of operating that I most affect at present is the intra-peritoneal one. I tie off the ovaries and broad ligament, and then amputate the uterus, as I would the thigh in a circular amputation, tying the uterine arteries just before I sever the neck of the uterus and burning out the uterine cavity thoroughly with the cautery. I do not think there has been much difference in the mortality following the two methods in my experience.

DR. M. H. RICHARDSON: The mortality in hysterectomies for fibroids is still so large that the question of interference should not be hastily decided; nor should the woman be advised to run so great a risk unless the indications are clear. In uncomplicated cases, in which the patient's strength is good, the mortality is small. Yet, in spite of all precautions, deaths do occur from causes beyond human control as well as from accident that may be avoided. Among the former are thromboses and embolisms; the latter include chiefly errors in technique and accidental contamination of the peritoneum from the uterine canal. The danger from avoidable errors is steadily diminishing, and we can predict with some confidence the result in a given case. Yet the risk is still considerable.

There are two indications for this procedure which may be pressing: the one a debilitating hæmorrhage, and the other an exhausting pain. Both indications not infrequently exist in the same patient. A third indication common to all large abdominal tumors is the existence of pressure symptoms. This last may be more important than all others. Among the less serious complications should be included the malignant degeneration that occasionally develops in the tumor. This, however, in my experience, is extremely rare —

so rare that it may be practically disregarded as an influencing factor in prognosis.

The most important indication for interference, perhaps, is great rapidity of growth. This symptom combined with hæmorrhage, or with discomfort, or with both, renders an operation imperative. Hæmorrhage itself, if it is causing serious debility and does not yield to palliative treatment, demands surgical interference. Long-continued pain or a discomfort that makes life unbearable, while not demanding operation, justifies it. Whatever the symptoms may be, we are not warranted in letting them continue until the strength is so reduced that the dangers from operation are materially increased.

The method of operation to be chosen depends upon the case, the length of the pedicle, the accessibility of the tumor, the necessity for speed. If the patient's strength justifies the more prolonged method of total extirpation, this is much to be preferred to the extra-peritoneal treatment of the stump. If the patient is so reduced that there is danger in prolonged manipulations we cannot use the intra-peritoneal method.

The Trendelenberg posture has made abdominal hysterectomy one of the most beautiful operations of modern surgery. In this position the dissection of the cervix can be carried out with perfect accuracy; the ureters can be isolated and protected, the blood-vessels seen and tied. In closing the wound the pelvic floor can be covered in with peritoneum, perfectly adjusted and sutured. General peritoneal infection can be avoided in this operation by means of sterile gauze barriers. In case of suspected infection vaginal drainage can be used successfully through the posterior cul-de-sac, either by means of rubber tubing, gauze wick, or by both. By this method even the more septic diseases of the uterus, like cancer, can be removed with small mortality. In one case I removed successfully the whole uterus containing a sloughing fibroid of the foulest description. There was no infection of the peritoneum whatever.

In the extra-peritoneal method the disasters that have occurred in my experience have been caused by an infection from the uterine canal. The danger from this source is also present in the total intra-peritoneal extirpation, but it may be materially lessened by preliminary irrigation and packing. In the extra-peritoneal treatment the infection is apt to take place at the time of amputating the tumor.

On the whole, hysterectomy is one of the most gratifying in the list of abdominal operations. The signs of the times point towards earlier and more frequent interference, with a corresponding increase in favorable results.

DR. A. T. CABOT said that he regarded the extra-peritoneal method as safest when a stump could be obtained and easily brought to the surface. He said that he had had a considerable number of operations for uterine fibromata, and perhaps he could show the dangers that he had met with best by reporting briefly the cases of death that he had had.

The first one was in a patient with a very large tumor, so large that many years before she had been advised never to have it operated upon, and had only been driven to this course by the excessive discomfort and almost helplessness that its size had entailed. The tumor grew down so into the vagina, that it could not be wholly lifted up and the pedicle had to be made through a portion about four inches in diameter before

impression, and certainly as much as three inches it had been compressed by the wire. The tension was so great upon this pedicle, that there was some sloughing both of the bladder and of the rectal wall. The fistulae, discharging fæces and urine, healed up after a time, and everything seemed to be going well; until she suddenly, about four months after the operation, developed uræmic symptoms, which were evidently due to the compression of the ureters, owing to a contraction of the scar tissue in the pelvis. Of this she died.

The second case was one in which a woman with a sloughing fibroid on the top of the uterus became pregnant. Dr. Cabot saw her at the hospital, after the fibroid had set up considerable peritonitis. She was quite sick when she first entered, but became somewhat better, and it was deemed wise to remove the tumor. The fibroid was found adherent over a considerably inflamed area of the peritoneum. It was easily separated and the uterus was removed with the fibroid. She lived only about forty-eight hours; and at the autopsy it was found that the peritonitis had started from that portion of the peritoneum that had been in contact with the sloughing tumor.

The only other case of death after the removal of the uterus that he had had, was in a healthy woman with a fibroid of considerable size. The stump was treated intra-peritoneally.

The amputation was made through the cervix, and the stump, which was cut in a cup-shaped manner, was carefully drawn together by interrupted sutures. The closure seemed perfect. This patient did exceptionally well for two days. Then, without any special abdominal pain, she began to vomit, and died of a mild, septic peritonitis, starting about the stump of the uterus.

In addition to these cases of complete removal of the uterus for fibroid, Dr. Cabot said he had a number of times shelled out small fibroids by simply splitting the peritoneal covering and turning them out of their capsule. These cases have all done well and in some of them very great relief of symptoms has followed. A small fibroid, wedged down in the pelvis, close to the neck of the uterus, may cause more pain and discomfort than a much larger one which rises into the abdominal cavity.

On one or two occasions, when the removal of the fibroid uterus appeared to present more than usual difficulty on account of the depth within the pelvis at which the uterus lay, he said he had contented himself with removing the ovaries. This was done, both with the object of checking the growth of the tumor, and also of checking the hæmorrhage, which in one case, at least, was a very troublesome symptom.

Hitherto these cases have done well; and although the want of success reported by other operators would lead him to think that he had been fortunate in not having after trouble, yet he was still inclined to resort to oöphorectomy in difficult cases, where the risks of the removal of the uterus appeared greater than the difficulties which the patient suffered from, would warrant.

DR. E. W. CUSHING, in closing the discussion, described the method by which in all cases the stump could be diminished by enucleating any masses of fibroid tissue which have grown near the cervix, so that finally nothing is left but the uterine tissue proper. In this way the stump should never be thicker than

the size of two thumbs. In thus enucleating and forming the stump, it is of the greatest advantage to use a rubber constrictor, for by its elasticity it allows nodules of fibro-tissue to be extracted from under it. After the stump is formed, a wire constrictor can be used if the operator prefer, although it is hard to see what advantage this offers over the rubber tubing.

In regard to selecting cases for operation, Dr. Cushing repeated that he would only operate where there was hæmorrhage, rapid growth or considerable pain, or where the tumor acted injuriously by compressing the rectum or ureter.

THE NEW YORK NEUROLOGICAL SOCIETY.

STATED Meeting, held at the New York Academy of Medicine, Tuesday evening, February 6, 1894, DR. M. ALLEN STARR, President, in the chair.

ELECTRICAL REACTIONS AND THEIR VALUE IN DIAGNOSIS AND PROGNOSIS.

The PRESIDENT said that he has seen statements from various sources, some very dogmatic and others sceptical, in regard to the value of electrical tests as an aid to diagnosis and prognosis in various forms of nervous diseases. A careful review of the literature of nervous diseases will reveal to any one that most men who have written books on this subject have gone right back to the original article of Erb, published in 1872, in the first edition of Ziemssen's Cyclopaedia, and have recopied Erb's diagrams and statements. Individuals who have had many opportunities of making electrical tests have noticed from time to time that their results did not correspond with the statements laid down by Erb. Their results, however, were not made public, or else they tried to explain them away, as if there was something wrong with them. A discussion on this subject, therefore, is very timely.

DR. C. L. DANA opened the discussion, and spoke of the value of electrical reactions in spinal lesions. In connection with this subject he has lately studied a certain number of cases in which he was able to test the reactions many times in the course of the disease. The tests were made in cases of anterior polio-myelitis, progressive muscular atrophy and bulbar palsy; also in one or two cases of facial palsy and locomotor ataxia.

It was absolutely necessary, Dr. Dana said, in making any comparative statements about our results, that we should understand how the reactions were taken by each observer, and what he means by reaction of degeneration. The reactions were subject to such variability, and it was so easy to deceive one's self, that the operation required an extremely judicial state of mind and great care. In the tests made by himself he employed an indifferent electrode, about the size described by Erb; this was to be tied down, not held by the hand, so that there were no variations in the amount of pressure. For the active electrode he employed a small, pointed electrode, the surface of which measures one square centimetre each way. By means of this you can get the muscular irritability at different parts of the muscle, you can see whether the contractions are sluggish or otherwise, and you also learn the diffusibility of the contraction, which is a form of reaction which has not been sufficiently noted. If an electrode with a large surface is employed, the diffusible reaction is not brought out with any certainty. The

small, pointed electrode can also be shifted to the motor point of the nerve, and thus the nerve reaction be obtained. In some cases the strength of the current required is so great that the point electrode gives rise to too much pain; in such a case he employs the ordinary-sized electrode. The electrode is first placed on the body of the muscle, and reaction obtained with a gradually increasing current; and then the same reaction with a gradually decreasing current. These reactions are compared with those on the opposite side and the operation repeated two or three times with a proper interval between, in order to allow the muscle to rest.

The three points that he has particularly investigated in connection with spinal lesions are: First, the relative irritability of the two poles; second, the character of the reactions, that is, whether they are sharp or sluggish, or sluggish and diffuse; and third, the course of the variations of the reactions in the different stages of the disease.

With regard to the relative irritability of the positive and negative poles, many of the recorded cases merely showed that the cathode exceeded the anode in irritability, without giving the exact number of milliampères required to produce contractions. Dr. Dana said he considered this an inaccurate method of making the measurements. In all reports it should be carefully put down how many milliampères are necessary to produce a positive pole contraction, and then a negative pole contraction, or *vice versa*. In this way, by following the course of the disease, we should find that each pole had a definite course of increased and decreased irritability, in accordance with the progress of the disease. The speaker exhibited a number of diagrams which he had prepared, showing the course of the polar irritability in several cases of progressive muscular atrophy, in two cases of anterior polio-myelitis and in one case of double facial palsy; in the latter case he was able to make daily examinations of both sides of the face for a number of weeks. His observations go to show that there is a difference between the course of the polar irritability in neuritis and that in progressive muscular atrophy and polio-myelitis. In neuritis there is a pronounced steady rise in the polar irritability, while in the spinal lesions it is very slight or absent. So far as his observations go, there is a true degenerative reaction in progressive muscular atrophy, as there is in polio-myelitis, but we only get it in certain stages of the disease. In all the descriptions of electrical degenerative reactions, the fact is spoken of that in normal muscles and in partly degenerated muscles the reactions are sharp and quick, but that when the muscles become degenerated the reactions are sluggish or vermicular. Further than this, with the point electrode there is a diffuse contraction of the muscle; that is, the whole belly of the muscle and even the adjacent muscles will contract. This diffusibility of the contraction, Dr. Dana said, he considered equally important with the sluggishness, although it does not always take place. It was better seen with the anodal contraction.

In conclusion, Dr. Dana thought we ought to revise many of our views of the reaction of degeneration; but it was too soon to formulate new views.

Dr. W. M. LESZYNSKY continued the discussion, confining his remarks more particularly to the value of electrical reactions in cases of traumatic neuritis. His method of making the examination, he stated, was very

similar to that outlined by Dr. Dana. The conclusions drawn by him were as follows:

(1) That the value of electricity as an accessory method in diagnosis and prognosis of disease of the peripheral nerves is not as universally recognized as its importance demands.

(2) That the result of this procedure often furnishes corroborative and conclusive evidence, where only a provisional diagnosis has been made.

(3) That the necessary technical skill in successfully pursuing such investigations and correctly interpreting the result can only be acquired through special study and practice.

(4) That the use of the faradic current alone is quite sufficient for diagnostic purposes.

(5) That, as a rule, the galvanic current is supplemental to the faradic, and in the absence of faradic irritability in nerve and muscle it is of the greatest service in prognosis.

(6) That the discovery of the reaction of degeneration is not an essential feature in the differential diagnosis as to the location of the lesion.

(7) That the peripheral nerve fibres possess an inherent power of regeneration which seems almost unlimited, the length of time required for the completion of the regenerative process varying from a few weeks to seven years or more. Therefore, in severe forms of injury, the cause, degree and character of damage to the nerves are often of greater importance in prognosis than the demonstration of the reaction of degeneration.

(8) That the presence of reaction degeneration, or partial reaction degeneration, is not incompatible with the preservation of motility in the same area. This paradoxical condition has been found in cases of lead-poisoning and a few others; but thus far the cause has been inexplicable.

(9) That strong currents are only rarely necessary. The weakest current that will produce a distinctly perceptible reaction is all that is requisite.

(10) That a decrease or disappearance of faradic irritability in nerve and muscle simply denotes an interference with the nutrition in the course of the motor tract between the multipolar cells in the anterior horn and the peripheral nerve distribution. It does not enable us to judge of the nature of the pathological process.

(11) That the character of the reactions does not differ, whether the lesion be situated in the cells of the anterior horn, the anterior nerve roots, the nerve trunks, or in their ultimate distribution. The same rule holds good in reference to the various cranial motor nerves and their nuclei, such as the facial, hypoglossal and spinal accessory nerves.

(12) When the farado-muscular irritability is lost, no reaction can be obtained by a rapidly interrupted galvanic current.

(13) The secondary current from an induction coil is the one generally used in testing faradic irritability. Owing to its high electro-motive force, the resistance encountered in the moistened skin may be disregarded.

(14) The difference in the poles of the faradic current is only a relative one, and cannot be determined by the usual tests as applied to the galvanic current. The electro-motive force in the secondary coil is greater at the "break" than at the "make." The electrode that is felt to be the stronger in its action is usually considered as the negative or so-called "faradic cathode."

(15) In some apparently healthy individuals the musculo-spiral nerve fails to react to strong currents applied with the "faradic anode," while a comparatively weak current from the "faradic cathode" calls forth a quick response.

(16) In a case of undoubted peripheral paralysis the faradic irritability may be preserved, but it almost invariably requires a stronger current to produce muscular contractions than upon the healthy side (quantitative decrease); Dr. Leszynsky said he has never seen a case where this could not be demonstrated within a few days after the onset of the paralysis.

(17) The character of the muscular reaction demands attention. A slow and labored contraction associated with decrease in faradic irritability denotes degenerative changes.

(18) The faradic irritability may return in persistent cases of peripheral paralysis without any perceptible improvement in motility.

(19) Electro-diagnosis is inapplicable in paralysis of ocular muscles.

(20) When the farado-muscular irritability is lost upon skin excitation, its presence may be demonstrated in the muscle for a longer time by means of acupuncture.

(21) If electricity is to be of any service to us in ascertaining whether the nerve trunk has been divided or not, as a result of traumatism, the examination must be made as soon after the injury as possible. We can then determine at once if special surgical interference is necessary. Should two or three weeks elapse before such examination, it will be impossible to state whether the absence of reaction is due to traumatic neuritis or to complete division of the nerve. Exploratory incision would then be called for.

(22) The tests with the galvanic current require adequate apparatus and a working knowledge of the relationship between electro-motive force, resistance and current strength. It also requires much time, patience and perseverance; hence its unpopularity.

DR. M. A. STARR spoke of the value of electrical reactions in cases of multiple neuritis. He reviewed the conclusions of Nothnagel, Pal, Gowers and others on this subject, and gave the histories of a number of cases of multiple neuritis coming under his observation. The first case reported was one of general alcoholic multiple neuritis, with total paralysis in both arms and both legs. In this case, within two months after the onset, when the paralysis was extreme and when no voluntary movement was possible in the muscles of the arm, forearm or hand, the electrical reactions differed completely in these localities; in the arm there was a diminution of response to both currents without polar changes; in the forearm there was a loss of faradic response and diminution of galvanic response without polar changes; in the hand there was loss of faradic response, diminution of galvanic response with polar changes.

In two other cases of alcoholic multiple neuritis, very great variations were present in muscles which were equally paralyzed. In a case of diphtheritic paralysis there was a total loss of contractility to faradism, but no polar changes to the galvanic current. In another case of diphtheritic multiple neuritis, in which ataxia rather than paralysis was a marked symptom, an interesting fact was noted. There appeared to be a slight weakness in the right supinator longus muscle. The electrical reactions of this muscle, however, were

found to be normal, the reaction to faradism being prompt, and the cathode closure contraction being greater than the anode closure contraction. For purposes of comparison the left supinator longus was simultaneously tested, there being no voluntary paralysis of this muscle whatever. It was found that the reaction to galvanism in this muscle showed polar changes, the anode closure contraction being greater than the cathode closure contraction, although there was no reduction in the faradic response. Here, then, was an observation which confirms the statement of Pal that electrical changes are sometimes present in muscles which are not paralyzed.

In closing his remarks, Dr. Starr said that every possible change to electrical reactions may be present in muscles affected in the course of multiple neuritis. The conclusion is inevitable, therefore, that to the electrical changes no very great diagnostic significance can be assigned. In the cases cited, there was no parallelism between voluntary power and electrical condition. Voluntary power in all the cases seemed to return before the electrical reactions became normal. Therefore we cannot project a reaction line upon a chart into the future and say that at a certain date, when the electrical reactions become normal, the voluntary power must necessarily return. Electrical reactions, while of some interest, are not to be taken as of great importance in the diagnosis of multiple neuritis.

DR. B. SACHS discussed the value of electrical reactions in dystrophies. In regard to the general subject of reaction degeneration, the speaker said he has been forced to the conclusion that there are only two points of value. The first and most significant feature of reaction degeneration was the loss of faradic response. The second was the sluggishness of the contraction. The variability between the anodal and cathodal contraction was extremely great, and he had long since abandoned the idea that the relationship between the two can be utilized in all cases either for the purpose of diagnosis or prognosis. Physiologists have demonstrated with considerable plausibility that the electrical excitation of nerves and muscles largely depends upon the rapidity and succession of single shocks. In muscles in which the faradic contractility seems to be absent, if you diminish the interruptions, you will often get a contraction, whereas you will not get it with the ordinary faradic machines we use. Dr. Sachs said he believed we could state that reaction degeneration was present in any given case if the faradic response was absent. He agreed with Dr. Dana's remarks regarding the variations in polar irritability in different stages of anterior polio-myelitis and other diseases. In Erb's diagrams, which have been so extensively copied, he does not differentiate between anodal and cathodal response. He does not make any distinction between the two poles. Dr. Sachs said he had found the greatest possible variability in the action of the two poles. In many cases, particularly in peripheral nerve palsies, he had found that the cathodal excitability was increased as long as the disease lasted. After full power had returned, the faradic excitability might still be diminished, or last for a period of time varying between several weeks and a year. In exceptional cases the faradic response remained normal from beginning to end, but the galvanic changes were pronounced.

The speaker said it was well to divide muscular

dystrophies into two classes, namely, primary muscular dystrophies and the so-called spinal amyotrophies. In the pure dystrophies we rarely got a definite reaction degeneration; that is, there was rarely entire absence of faradic response and marked sluggish reaction, excepting in the very last stages of the disease, when so little muscular fibre was left that we could not expect to get either faradic or galvanic response. In primary muscular dystrophy, therefore, there was no typical reaction of degeneration. In other than primary muscular dystrophies, we got a very strong resemblance to the typical reaction degeneration. In progressive muscular atrophy of spinal origin reaction of degeneration might be present in its entirety; but we often found partial reaction of degeneration and other irregular types of electrical reaction.

As regards the value of electrical reactions in diagnosis and prognosis, Dr. Sachs said he was fully in accord with the statements made by the previous speakers. He still believed that Erb's observations were extremely well founded and held good in the majority of cases. It was certainly true that if the faradic response — in a case of facial paralysis, for instance — was never lost, in nine cases out of ten recovery will be more prompt than where it was lost. That the faradic irritability returns in some cases before the power, as claimed by Dr. Leszynsky, he thought exceptional, to say the least. It was much more certain that the power returned long before the faradic response did, in the vast majority of such cases.

As regards the value of electricity as a means of prognosis in cases of muscular dystrophy, the speaker thought it was very slight. The senses of sight and touch will teach us much more than the electrical examination in such cases. By the degree of response to the faradic and galvanic currents we can get some idea as to the condition of each individual muscle, but no definite conclusions can be drawn. In some cases of typical muscular dystrophy, certain muscles unquestionably do recover; others do not. In the cases which recover, the electrical reactions do not undergo any decided changes.

DR. A. D. ROCKWELL said he agreed with Dr. Sachs that the main importance of electricity as an aid to diagnosis was in connection with the absence or presence of the faradic reaction. The importance of this subject to the general practitioner was impressed on his mind by a case that recently came under his observation. The case was one of facial paralysis, and the patient for seven weeks had been under the care of a general practitioner, who treated him with the faradic current without any benefit. Under the use of galvanism the patient at once began to improve. The following case indicates very positively the value of electricity as a diagnostic agent. The case was one of typical facial palsy on the right side from peripheral causes. During the course of the patient's recovery from this, a paralysis occurred on the left side of the face; this started as a peripheral paralysis, but on testing the muscles with faradism, it was found that they responded with perfect facility. Therefore, it was evident that the paralysis on this side was central. Shortly afterwards the patient had a second attack involving the right side of the face, again peripheral. Dr. Rockwell said that in ovarian or uterine diseases of an inflammatory character, the faradic current produces no improvement, but rather aggravates the pain;

while in non-inflammatory conditions the faradic current will relieve the pain.

DR. GEORGE W. JACOBY said that the statements made in the text-books on this subject are too dogmatic. The diagnostic value of electricity is limited to certain peripheral affections, and even there it is not as great as originally claimed. In prognosis, also, we must limit its value. In a number of cases of facial paralysis of long standing, he has found it impossible to obtain any reaction of degeneration. In a couple of other cases in which the paralysis had entirely disappeared with the exception of a slight obliteration of the labio-nasal fold, there was marked reaction of degeneration. These are exceptional cases, and he could give no explanation of them. Cases have been published in which there was a reaction of degeneration found in cerebral palsies; also in cases of primary dystrophy.

DR. C. A. HERTER referred to the electrical reactions in some cases of cerebral palsies. In one case under his observation, a woman aged seventy years, the patient had a series of slight apoplectic attacks, succeeded in time by complete paralysis of the right side of the body (face, arm and leg) and complete motor aphasia; at the end of one week distinct atrophy of the muscles of the forearm was noticeable, and at the end of one month it was very pronounced. The faradic irritability of certain muscles of the forearm was very much reduced. The contractions were exceedingly sluggish, and the reaction of degeneration was undoubtedly present. The galvanic irritability of these muscles was somewhat diminished. Dr. Herter also referred to the rapidity with which the reaction degeneration makes its appearance in some cases of injury to the spinal cord. In two instances coming under his observation it was pronounced at the end of four days.

DR. L. STIEGLITZ agreed with Dr. Sachs that the most important feature of the reaction of degeneration is the sluggishness of the contraction. It must be borne in mind that muscles of coarse fibre react much more sluggishly than those made up of fine fibres.

DR. G. M. HAMMOND said he agreed in the main with the statements made by the previous speakers. Like Dr. Sachs, he had noticed that muscles which do not respond to a rapidly interrupted faradic current will respond to a slowly interrupted one. The reverse is true with the galvanic current. With a battery that he employs he can get about 170,000 interruptions per minute, and he has found that the greater the number of interruptions, the stronger the current required. This rule applies in both healthy and diseased conditions.

DR. STARR narrated the history of a case of facial paralysis that came under his care. An examination showed increased contractility to galvanism in the muscles, and perfect preservation to faradism, the cathode being greater than the anode. On the strength of this he gave a favorable prognosis. After six weeks' careful treatment the reactions remained about the same, but the paralysis was no better. The patient then went to another neurologist who made a similarly favorable prognosis, and applied electricity with equally unfavorable results. That is now a year and one-half ago; the reactions are still normal, but the face remains just as much paralyzed as it ever was.

DR. DANA exhibited a Portable Perimeter which he has devised. It is made by Meyrowitz & Co., of New York.

Recent Literature.

A Treatise on Diseases of the Rectum, Anus and Sigmoid Flexure. By JOSEPH M. MATHEWS, M.D., Professor of Surgery, and Clinical Lecturer on Diseases of the Rectum, at the Kentucky School of Medicine, etc. Six chromo-lithographs and numerous illustrations; 537 pages. New York: D. Appleton & Co.

This book has been written to record individual experience acquired during fifteen years' practice as a rectal specialist. The intention has been to state only what is substantiated by fact. When this differs from statements of other authorities, both conclusions are given and the reader is left to decide between them.

Besides discussing the subjects usually treated in works of this class, namely, hemorrhoids, fistulæ, rectal ulcers, fissure stricture, cancer, tumors and malformations, the writer has introduced chapters describing disease of the sigmoid flexure, rectal neuralgia, hysteria, rectal reflexes, rectal antisepsis, and a new operation for fistulæ.

The book is an attractive volume, clearly printed and well indexed. The style is concise, and the author's statements direct. His ideas are practical, and are interestingly presented. Dr. Mathews states definitely what he thinks and what his experience has taught him. He makes no effort to harmonize it with oft-quoted ideas or theories if it does not so correspond. If a method of treatment is efficient, he so describes it. If in his practice he has found the reverse true, he condemns it in no doubtful terms. Such a book is easy to read and understand. It is one which contains information of value, both to the specialist and general practitioner. It is well illustrated.

Lectures on Mental Diseases. By HENRY PUTNAM STEARNS, A.M., M.D. Pp. 627. Philadelphia: P. Blakiston, Son & Co. 1893.

These twenty-nine lectures form, as a whole, a useful text-book. Although no new light is thrown on the subject, the established facts relating to the different features of insanity are graphically stated, and the numerous illustrative cases will appeal strongly to the interest of "the student and practitioner, for whom the volume is especially designed."

The classification offered is a very satisfactory one for its purpose. It is of a mixed ætiological and symptomatological variety. The term "paranoia," which has become so general in its application, the author looks upon as a palpable misnomer, on the ground that it is a Greek name for insanity in general applied to a special form, and one, moreover, which has no relations with any basis of nomenclature. He accordingly uses the more accurate and familiar term "primary delusional insanity."

In the chapter on "Insanity of the Puerperal Period"—one of the best in the book—we find the suggestive statement, based on the statistics of thirty-nine recoveries, that age was a factor of no importance in promoting the prognosis or duration of the disease, and that the recoveries were not particularly hastened by early admissions.

We regret that so high an authority has not thought it necessary to give us his views on the relations between ordinary insanity and syphilis, or to accord more than a brief allusion to the recognized influence of that important agent in general paresis. The diagnosis of the latter disorder is inadequately considered also,

not only as regards cerebral syphilis, but also ordinary diffuse and focal lesions of the brain. Some suggestions as to the method of examining the insane for certification, would surely have been welcome to the general physician; and we are left in the dark as to many of the borderland states between mental health and disease, as well as the simulation of insanity.

These omissions, however, do not seriously detract from the value of the book, which is sure to find favor with those for whom it is designed, by reason of its thoroughly practical tone. Extracts from the laws of the different States and Territories of the United States, which relate to the general care of the insane, are appended.

Rest and Pain. A Course of Lectures on the Influence of Mechanical and Physiological Rest in the Treatment of Accidents and Surgical Diseases, and the Diagnostic Value of Pain. By the late JOHN HILTON, F.R.S., F.R.C.S., Surgeon Extraordinary to Her Majesty the Queen, Consulting Surgeon to Guy's Hospital, Member of the College Council, President of the Royal College of Surgeons of England, Member of the Court of Examiners, and Professor of Anatomy and Surgery, etc. Edited by W. H. A. JACOBSON, M.A., M.B., M.Ch.Oxon., F.R.C.S., Assistant Surgeon to Guy's Hospital, Surgeon to the Royal Hospital for Children and Women. Fifth edition. London and New York: George Bell & Sons. 1892.

There can be no doubt of the value of this book. It is more than a monograph, and can be safely placed in the catalogue of surgical classics. The present edition is satisfactorily edited. The printing and the plates are passable. The book is in the form of eighteen lectures, and no one who is interested in surgery should neglect reading the work. There are few books in the English language which can give the reader more food for thought than Hilton's Lectures on Rest and Pain.

The Use of Antiseptics in Midwifery: Their Value and Practical Application. By ROBERT BOXALL, M.D. (Cantab.), M.R.C.P. (Lond.), Assistant Obstetric Physician to, and Lecturer on Practical Midwifery at, the Middlesex Hospital; formerly Physician to the General Lying-in and Samaritan Free Hospitals, etc. London: H. K. Lewis. 1894.

This little pamphlet is of considerable interest and value. The statistics given for the General Lying-in Hospital certainly show most admirable results. The entire absence of deaths from sepsis in the wards of so large a hospital for four years is an admirable record, and the confinement of more than a thousand consecutive out-patient cases without a single death is a result that can be rivalled by few institutions. The conclusion which the author draws from the Registrar General's Reports, as to the standard of asepsis among the general profession in England, are indeed sad, and are, we believe, even worse than that which undoubtedly exists among the less carefully trained portion of the profession in this country. A death roll of 2,356 unnecessary deaths in England, in a single year, is certainly sufficient justification for the publication of this work. The language of the pamphlet is clear, concise, and striking; the precautions recommended are excellent, and leave nothing to be desired, except the use of the nail-brush and nail-cleaner, which, strangely enough, are never mentioned.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, MARCH 29, 1894.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE REGISTRATION OF AND PREVENTIVE
MEASURES AGAINST TUBERCULOSIS.

THE question of the wisdom of the registration of tuberculosis and the adoption of other preventive measures against this disease—by the dissemination of circulars, the affixing of placards upon houses occupied by the tuberculous, and the disinfection of rooms and apartments where there has been a death from tuberculosis—has occupied the attention of some local boards of health, notably in New York and Philadelphia, and been pretty thoroughly discussed by some of our medical societies this winter. The difficulty and delicacy of the problems involved are unfortunately in direct ratio to the importance of the question.

The American Public Health Association, at its last meeting, and the Pan-American Medical Congress adopted resolutions in favor of registration. In England, also, some of the local boards of health have petitioned the Local Government Board for sanction to include pulmonary tuberculosis as a disease notifiable under the provisions of the Infectious Diseases Act. The whole question of tuberculosis is now under the investigation in England of a Royal Commission.

The College of Physicians of Philadelphia held a special meeting in January to consider the proposed action of the board of that city in reference to the registration of tuberculosis. The following amended form of a resolution, offered by Dr. L. F. Flick, was under discussion.

Whereas, Tuberculosis is now known to be a contagious disease; and

Whereas, The methods by which the disease is conveyed from the sick to the well are now clearly understood; and

Whereas, It has been shown that the room which is occupied by a consumptive during the infectious period of the disease, and the furniture and the bed-clothing which have been used by him, become infected, and are liable to convey the disease to others who may occupy or use them subsequently; and

Whereas, Tuberculosis, owing to its long duration, cripples the bread-earning capacity of the family, when it occurs among the poor, to such an extent that the want

and hardships which follow in its wake prepare the healthy members of the family for the disease; therefore be it

Resolved, That we recommend to the Board of Health of the City of Philadelphia the registration and disinfection of houses which have been infected by tuberculosis;

Resolved, That we recommend to the City Councils of the City of Philadelphia the establishment of a municipal hospital for the treatment of persons suffering from tuberculosis.

We regretted not having space at the time for the publication of the full discussion, which was participated in by a number of the prominent members of the College of Physicians, and dealt with the various sides of the questions at issue in a broad and enlightened spirit. At the end of the discussion, the college rejected the amended resolution offered by Dr. Flick, and voted the following resolutions offered by the Council of the College:

Resolved, That the College of Physicians believes that the attempt to register consumptives and to treat them as the subjects of contagious disease would be adding hardship to the lives of these unfortunates, stamping them as the outcasts of society. In view of the chronic character of the malady, it could not lead to any measures of real value not otherwise attainable.

That strict attention on the part of physicians in charge of the individual cases insisting on the disinfection of the sputum and of the rooms, on adequate ventilation, and on the separation of the sick from the well as far as possible, will meet the requirements of the situation so far as they practically can be met, and better than any rules that, for diseases so chronic, can be carried out by a board of health.

That the College of Physicians respectfully requests that no official action be taken in the matter by the Board of Health, except the insisting on the disinfection of rooms in which consumptives have lived and died in instances in which such procedure is not likely to have been adopted under the direction of the attending physician.

On the other hand, our readers will remember that in November last Dr. H. M. Biggs, of the Bureau of Bacteriology and Disinfection, in an elaborate report to the Board of Health of the City of New York, made a number of recommendations having in view the more efficient limitation and prevention of pulmonary tuberculosis. The Board, acting on the advice of the Sanitary Committee, has since adopted a series of measures designed to carry these recommendations into practical effect.

In the first place, it is proposed to place a placard upon the door of every apartment that has been occupied by a consumptive patient, stating this fact and that it has thus become infected. The remainder of the inscription reads as follows:

It must not be occupied by other persons than those now residing here until an order of the Board of Health directing that it be cleansed and renovated has been complied with.

Name of occupant ———. Floor ———. Street No. ———.
This notice must not be removed until the order of the Board of Health has been complied with.

Secondly, a circular has been prepared, which was to be issued to all physicians practising in the city,

stating that the Board has resolved to adopt the following preliminary precautions:

(1) The Department will hereafter register the name, address, sex and age of every person suffering from tuberculosis, so far as such information can be obtained, and requests that hereafter all physicians forward such information on the postal cards ordinarily employed for reporting cases of contagious diseases. This information will be solely for the use of the Department, and in no case will visits be made to such persons by the inspectors of the Department, nor will the Department assume any sanitary surveillance of such patients unless the person resides in a tenement-house, boarding-house, or hotel, or unless the attending physician requests that an inspection of the premises be made. In no case where the person resides in a tenement-house, boarding-house, or hotel, will any action be taken if the physician requests that no visits be made by inspectors and he is willing himself to deliver circulars of information or furnish such equivalent information as is required to prevent the extension of the disease to others.

(2) When the Department obtains knowledge of the existence of cases of pulmonary consumption in tenement-houses, boarding-houses, or hotels, (unless the case has been reported and the attending physician requests that no visits be made,) inspectors will visit the premises, will leave circulars of information, and will instruct the person suffering from consumption and the family as to the measures which should be taken to guard against the spread of the disease. If it is considered necessary, the inspector will make such recommendations for the cleaning or renovation of the apartment as may be required to render it free from infectious matter.

(3) In all cases where it comes to the knowledge of the Department that premises which have been occupied by a consumptive have been vacated by death or removal, an inspector will visit the premises and direct the removal of infected articles, such as carpets, rugs, bedding, etc., for disinfection, and will make such written recommendations to the Board as to the cleaning and renovation of the apartment as may be required. An order embodying these recommendations will then be issued to the owner of the premises, and compliance with this order will be enforced. No other persons than those residing there at the time will be allowed to occupy such apartments until the order of the Board has been complied with. Infected articles will be removed by the Department, disinfected, and returned without charge to the owner.

(4) In the prevention and treatment of pulmonary tuberculosis it is of vital importance that a positive diagnosis should be made at the earliest possible moment, and that the value of bacterial examinations of the sputa for this purpose may be at the service of physicians in all cases not under treatment in hospitals, the Department is prepared to make such bacteriological examinations for diagnosis, if samples of the sputa, freshly discharged, are furnished in clean, wide-necked, stoppered bottles, accompanied by the name, age, sex and address of the patient, duration of the disease, and the name and address of the attending physician. Bottles for collecting such sputa, with blank forms to be filled in, can be obtained at any of the drug stores now used as stations for the distribution and collection of serum tubes for diphtheria cultures. After the sputum has been obtained, if the bottle with the accompanying slip filled out is left at any one of these stations, it will be collected by the Department, examined microscopically, and a report of the examination forwarded to the attending physician, free of charge.

(5) The authorities of all public institutions will be required to furnish to the Department the name and last address of any consumptive coming under observation within seven days of such time.

This circular concludes in the following words: "It is the earnest wish of the Board of Health that all practising physicians in this city co-operate with the Board in an earnest and determined effort to restrict the ravages of the most prevalent and formidable disease with which we have to deal."

In the third place, a circular has been prepared for general distribution, especially among consumptives and their families, which treats of the nature of the disease, the special danger of infection from the sputa, and the measures necessary for protection, and includes a number of general sanitary directions. While endeavoring to impress upon the public the contagiousness and perils of the disease, it is hopeful in tone and encourages those affected with it and all coming in contact with them, to unite in an active crusade against it. "Consumption," it states, "can often be cured if its nature is recognized early, and proper means are taken for its treatment. In a majority of cases it is not a fatal disease. . . . A person suffering from consumption may often not only do his usual work without giving the disease to others, but may also get well, if the sputum is properly destroyed." The circular also urges that whenever a person without medical attendance, is thought to be suffering from consumption, the name and address should be sent at once to the Health Department in order that an investigation of the case may be made.

A law may be good in the abstract, but it is practical only in so far as it secures the co-operation of the community which it affects to such an extent as to permit its enforcement without excessive annoyance and expense; moreover, no law is good which causes more harm to society than it cures. The same may be said of the registration or notification of such a disease as tuberculosis, and of the adoption of general preventive measures against it. Nobody would advocate dealing with tuberculosis as with leprosy. Its chronicity is sometimes very great, and we all have before us numerous examples of those constantly and intimately exposed to its infectious principles with impunity. At what stage shall a suspected case of tuberculosis be reported?

We are disposed to sympathize, in a measure, with the position taken by Dr. Da Costa, and with Dr. J. S. Billings's statement in a letter read at the meeting of the College of Physicians:

I am doubtful as to what the decision of the College should be on this point. I presume that there are about six thousand people in Philadelphia affected with consumption, and that a considerable proportion of these have contracted the disease in infected houses. If it were possible by a systematic notification for the Board of Health to locate a considerable number of these infected houses, what steps would it take to purify them? How would it deal with those of the poorer classes who are affected with this disease, and with their furniture, bedding and rooms?

Until these questions are answered, I do not find it possible to form a definite opinion as to whether it is worth while to put in force a compulsory system of notification.

THE RÔLE OF ALCOHOL IN THE CAUSATION OF CIRRHOSIS OF THE LIVER.

CIRRHOSIS, or more properly sclerosis, of the liver, also annular cirrhosis and common atrophic cirrhosis (gin-drinker's liver) has been long regarded as chiefly of alcoholic origin. The earlier writers, as Budd and Frerichs, speak of alcohol as the ordinary exciting cause; Murchison states that he had never seen a case due to any other cause; and Frerichs adds that while there may be other causes, yet we are totally unacquainted with them. This etiological conception, based on clinical observations, has been found to be too exclusive.

Chauffard, in his masterly article on "Diseases of the Liver," in the *Traité de Médecine*, sums up his etiological classification under three heads: (1) toxic, (2) infectious, (3) dystrophic agencies, and assigns to alcohol a chief place among the toxic causes. Even here the causation is more complex than might be supposed, for the alcohol of ordinary consumption is not a constant and always uniform chemical compound, but a product of very variable and often sophisticated composition.

Létienne has taken up the subject in a recent number of *La Médecine Moderne* (February 21, 1894). While recognizing the fact that the influence of alcohol on the liver may determine a hypertrophic form of cirrhosis as well as an atrophic form, he proposes the question: "Is alcohol necessary to the establishment of atrophic cirrhosis? Is it sufficient of itself to engender this disease?"

First of all, comes the evidence from physiological experimentation. The first experiments on alcohol-poisoning were made by Dahlstrom in 1852, and by Duchek in 1853. The subjects were dogs. The autopsy indicated no lesion of the liver. The experiments of Perrin, Lallemand and Duroy, in 1860, showed that in poisoning by alcohol the different viscera retained unequal proportions, and the liver more than any other; they did not, however, indicate any particular anatomical lesions in this organ. Later, Kremiansky (1868) and Magnan (1869) obtained marked hepatic lesions; they noted cellular steatosis (acute fatty degeneration) without traces of sclerosis. The results of Rugé (1870) are the same. Pupier, in 1872, observed fatty accumulation in the livers of fowls poisoned by alcohol. Sabourin, in 1879, poisoned guinea-pigs with alcohol, and obtained "central steatosis of the lobule, with peri-sub-hepatic phlebitis." In 1884, Dujardin-Beaumetz and Audigé made an important series of observations on hogs. The anatomical examinations made by Cornil did not reveal any processes of interstitial hepatitis. Some of these hogs were dosed for a series of years with various kinds of alcohol.

Straus and Blocq in 1887 noted lesions more ad-

vanced and well defined. They produced in hares, which they had been able to keep longest under the influence of alcohol, an embryonic infiltration of the portal spaces (third month), which became more pronounced and ended by encircling the lobules about the seventh month, without, however, presenting the aspect of a dense fibrous tissue.

Other experimenters, as Maret, Combemale and Strassmann, noted the state of the liver in animals poisoned by alcohol, and found only fatty degeneration of the parenchyma. Laffitte, in 1892, in his graduating thesis compares the lesions produced as a result of experimental alcohol-poisoning with those of Lannec's cirrhosis. In the hare, he says, the prolonged ingestion of alcoholic liquids produces lesions which have no relation with common cirrhosis. The hepatic cell is almost always damaged, the connective-tissue is never irritated. *Per contra*, in studying chronic experimental lead-poisoning, he has been able to reproduce an atrophic sclerous hepatitis which has the greatest similarity to Lannec's cirrhosis.

Some experiments by Richter (1892) differ somewhat from the foregoing, and confirm those of Straus and Blocq. He obtained pathological processes strikingly like those of annular cirrhosis. There are, however, differences in the systematization of the sclerous processes, according to the animal under experimentation. The cirrhosis is peri-portal in the hare, peri-hepatic in the dog.

The writer in *La Médecine Moderne* thinks it demonstrated as a result of all this experimentation that atrophic cirrhosis is not a simple affection, due solely to the effects of the poison ingested upon the walls of the blood-vessels which this traverses in the hepatic parenchyma. When we make section of a cirrhotic liver, the lesions which we see under the microscope are not simply an expression of the action of alcohol on elements of the tissue: they are the effect of complex causes. The alcohol has a certain part, but infection or toxic-infection also impresses its stamp on the organ. The liver undergoes, from the fact of its slow impregnation with alcohol, a profound depreciation; it tolerates badly even the common infections which assault it. There comes a time when it can no longer react against them, and it suffers degeneration. The nobler tissues as they perish, are replaced by a connective-tissue proliferation.

It has been remarked that the anatomical schemes which serve to classify the cirrhotoses have not in nature the rigorous exactitude represented in the didactic treatises. Recent writings (as those of Létienne and Hanot) tend to relegate to a second rank the rôle of the peri-vascular connective-tissue, and to substitute for it that of the hepatic cell. There is no hepatic sclerosis without previous cellular alteration. At the ultimate and most characteristic periods of atrophic cirrhosis, there exists a veritable consumption of the liver. It has lost the faculty of making those efforts of struggle and of regeneration, which are observed in normal conditions. The liver becomes inactive, almost

without a physiological rôle, secreting insufficient bile without colored quality, leaving in the blood the principles it should eliminate. The normal deglobulization no longer takes place in its cells. The corpuscular *débris* appears in the urine, in the liquid of ascites; and the blood, which is charged with these waste elements, gives to the tissues a urabilinic, ictteroid tint.

These considerations have lately been presented by Hanot in an interesting study on alcoholic cirrhoses. Neither this writer nor the author of the article before referred to deny the sclerogenous power of alcohol; they only point out that this toxic agent is but one factor, and they emphasize the rôle of other toxic agents in the production of the same sclerotic phenomena. There is a cirrhosis caused by lead-poisoning, of a very typical kind, and of which we are beginning to learn much. There is a tuberculous cirrhosis, and there are certain acute infectious cirrhoses, distinct from every form of grave icterus, and which end in the same atrophic degeneration as alcohol. Atrophic cirrhosis of the liver may be the result of divers influences, certain of which are now known. It offers a uniform type of reaction of the hepatic tissue towards very varied irritant causes, and illustrates this principle of general pathology that the tissues have but limited means of reacting against agents of different species and indefinite number.

MEDICAL NOTES.

REDUCTION IN THE ARMY LIBRARY APPROPRIATION.—The House Military Committee has again cut down the appropriation for the Army Medical Library from \$10,000 to \$7,000.

ILLNESS OF SIR FRANCIS LAKING.—Sir Francis Laking, private physician to the Prince of Wales and surgeon-apothecary to the Queen, is reported to be dangerously ill in London.

THE HAMBURG CHOLERA INSPECTOR.—Surgeon Woodward who acted so efficiently as cholera inspector at Hamburg last summer has been ordered to the same port for the coming season.

CHOLERA IN RUSSIA.—On the first of March all the governments of the Russian Empire, with the exception of Volhynia, Kovno, Plock and Tchernigoff, were officially declared free from cholera.

ADJUNCT PROFESSOR OF PEDIATRICS.—W. T. Northrup, M.D., of New York, has been recently elected Adjunct Professor of the Diseases of Children in the Bellevue Hospital Medical College, as the associate of Dr. J. Lewis Smith who has held the full professorship for over thirty years.

EXAMINATIONS FOR THE UNITED STATES ARMY MEDICAL CORPS.—In view of the possibility of the reduction of the Medical Corps from one hundred and twenty-five to ninety assistant surgeons, by action of Congress at its present session, and to save possible loss of time and expense to candidates if such action be taken, the examinations appointed for March and

April, 1894, will, by order of the Secretary of War, not be held until further notice. It is probable, that, if the Corps should not be reduced, the Examining Board will be convened in the fall of 1894. Of this, notice as early as possible will be given.

SMALL-POX EPIDEMIC IN BROOKLYN, N. Y.—The Brooklyn Board of Health has declared small-pox to be epidemic in that city. There are at present over one hundred cases under care, ninety-one being in the hospital which can accommodate but one hundred and twenty. A requisition has been made upon the State for tents, three having already been set up in the hospital grounds. An appropriation of \$18,000 has been granted from the Emergency fund for special sanitary work, and a general vaccination has been ordered. The spread of the disease is now thought to have been caused by a ball given January 31st by some organization known to but not named by the authorities.

PRIZES OF THE SPANISH ACADEMY OF MEDICINE.—The Spanish Royal Academy of Medicine offers its annual prize for the best essay on the following subject, "Clinical and Therapeutical Study of Chronic Affections of the Intestine." The A. E. G. Cano Prize will be awarded for the best essay on "Infectious Endocarditis." Essays may be written in Spanish, Portuguese, French, Italian, German, or English, and must be sent to the Secretary of the Academy, 22 Montera, Madrid, before September 15, 1894.

AN INDIAN MEDICAL CONGRESS.—A proposal laid before the Calcutta Medical Society to have a general Medical Congress in India has met with much favor; and the First Indian Medical Congress will be held in Calcutta in the beginning of January, 1895. Physicians practising in every part of the world are invited to take part, especially those in India and the East. The Congress will comprise the following sections: (1) Medicine, including Pathology; (2) Surgery; (3) Obstetrics and Diseases of Women and Children; (4) Public Health; (5) Medico-legal Medicine and allied subjects.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—During the week ending at noon, March 28, 1894, there were reported to the Board of Health of Boston, the following numbers of cases of acute infectious disease: diphtheria 46, scarlet fever 48, measles 10, typhoid fever 6, small-pox 5 and 1 death. During the week one case of small-pox was reported to the State Board of Health from Melrose.

A NEW PUBLIC BATH IN BOSTON.—A new public bath-house has been opened at the South Cove district in Boston where bathing facilities can be had for a nominal sum, both summer and winter. It is a private concern backed by persons interested in hygienic charity, and will help to fill the need which is so marked in Boston of a large, well-appointed bathing-place during the cold months when the summer baths are unavailable.

THE COMMITTEE ON PUBLIC HEALTH.—The Committee on Public Health of the Massachusetts Legislature has reported adversely on a proposed bill to require patent medicine bottles to have on them a label stating the percentage of alcohol in the medicine, and also adversely on a bill requiring cans and receptacles used by milk-dealers to be kept free from impurities.

THE MASSACHUSETTS HOSPITAL FOR DIPSO-MANIACS.—The Committee on Public Charitable Institutions has rejected a bill introduced to provide further luxuries for the Hospital for Dipso-maniacs and Inebriates in Foxboro. It was proposed to erect a gymnasium and a swimming-tank for the patients.

A BEQUEST PAID TO THE SPRINGFIELD HOSPITAL.—The Springfield Hospital has received during the week the bequest of thirty thousand dollars, under the will of the late Mr. Horace Smith. Among other charitable institutions which received at the same time the payment of the bequests to them were the Home for Friendless Women and Children (thirty thousand dollars), and the Springfield Home for Aged Women (fifteen thousand dollars).

SMALL-POX IN PORTSMOUTH, N. H.—A case of small-pox was discovered in Portsmouth on March 25th in a farmhouse just outside the city:

NEW YORK.

HOSPITAL SATURDAY AND SUNDAY ASSOCIATION.—The distributing committee of the Hospital Saturday and Sunday Association met in the Mayor's office on March 20th and divided \$48,000 received from the annual collection among thirty-three institutions represented in the Association. Mount Sinai Hospital received the largest amount, \$5,290, and St. Luke's the next largest, \$5,153. The total sum collected this year was \$58,300. Of this about \$7,000 was specially designated for certain hospitals, and the expenses of the Association amounted to some \$3,000.

A RAID ON ABORTIONISTS.—On March 23d the police arrested sixteen advertising abortionists simultaneously in different parts of the city. The arrests were made at the request of the New York Society for the Enforcement of Criminal Law, which, through a skilful male and female detective, had secured evidence for the prosecution of the offenders. Some of the accused succeeded in securing bail, the bonds in each case being fixed at \$2,500.

PUBLIC HEALTH.—The unprecedentedly mild and pleasant weather that has prevailed during the month of March has had a marked effect upon the public health and reduced the death-rate of the city to a very gratifying extent. During the week ending March 17th the number of deaths reported was only 787, while in the corresponding week of last year, when the estimated population was at least 65,000 smaller than at present, the deaths amounted to 1,110. This mortality is also 175 lower than the average for the corresponding weeks of the past five years. Measles continues to be the most prevalent of the contagious

diseases. During the week ending March 17th there were reported 309 cases, with 25 deaths, and during the week ending March 24th, 375 cases, with 29 deaths. Diphtheria increased from 187 cases and 40 deaths to 220 cases and 53 deaths. Small-pox and scarlet fever do not show any material change; but there was some decrease in the mortality from pneumonia, and the deaths from influenza decreased from 12 to 4. There are very few cases of typhoid fever reported, and during the week ending March 17th there were but 2 deaths from this disease.

DEATH OF DR. STANARD.—Dr. Alfred Cushman Stanard, one of the most promising young physicians in the city, died at the New York Hospital on March 20th of peritonitis resulting from appendicitis. On the 16th he was operated upon, and at first it was hoped that the procedure would be successful in saving his life, but an extension of the peritonitis soon followed. Dr. Stanard was born in New York and was twenty-nine years old at the time of his death. He was graduated from the Medical Department of Harvard University in 1889, and afterwards served as an interne at the New York Hospital. Later he was appointed one of the attending physicians to that institution.

Miscellany.

AUTOPSY ON THE GREENWICH ANARCHIST.

THE autopsy recently made on the body of the man killed in Greenwich, England, by the explosion of a bomb held in his hand, is of considerable interest as showing the variety of lesions possible in such an accident.

The report shows¹ that the man held the bomb in his left hand about on the level of the abdomen. It is remarkable how little damage was produced by the bomb. The left hand and wrist were blown away and the tendons left hanging. A circular opening over an inch in diameter, with a charred margin, was found a little to the right and above the umbilicus. Posteriorly there was an almost linear wound of exit below the last rib on the right side. On the left thigh and leg there were several charred wounds of varying extent and depth, while on the right thigh there were two deep wounds extending nearly to the femur, one in front and one on the outer side over the trochanters, which must have been very nearly on the opposite side of the body from the bomb. In this latter wound a piece of metal was found. As a rule, no pieces of metal were found in the wounds, but many bits of clothing.

On opening the abdomen some intra-peritoneal hemorrhage was at once seen. This was due to great contusion and laceration of the right lobes of the liver, especially of the quadrate lobe and the adjacent part of the right lobe from the velocity of the air surrounding the bomb rather than to the metal itself. The gall-bladder had escaped injury. None of the intestines at this stage appeared to have been damaged, but on the removal of the peritoneum it was at once found that there was a large amount of retro-peritoneal hæmorrhage.

¹ Lancet, February 24, 1894.

rhage. Careful examination showed that the second part of the duodenum had been ruptured on the right side for rather more than an inch, and that the anterior surface of the right kidney was extensively lacerated. All the other abdominal viscera, including the stomach, which contained food, and the other portions of the intestine, were uninjured. The thoracic viscera and brain were quite normal.

THE FOREIGN QUARANTINE OF IMMIGRANTS.

In an editorial upon the request of the United States delegates to the International Sanitary Conference, that proper means be taken by European governments to prevent cholera and other infectious diseases from being brought to this country, the *Lancet* says:

"Precautions should be enforced, if not on the American side, then at the point of departure. The latter is the solution of the difficulty which the American Government desires to submit to the European Powers. In the name of humanity and of good neighborly feelings, care should be taken not to ship over to America infected clothing or persons likely to convey infectious or contagious diseases; but, if this principle does not suffice, then, even from selfish motives, the European Governments should act in the manner desired. A great deal has been said about the pilgrimages to Mecca, and it has been urged that, in English ships alone, as many as 20,000 pilgrims have been taken to Mecca in one single season; but this is nothing when compared to the 400,000, or so, immigrants who yearly go over to America. This great current of humanity travelling through Europe on its way to the New World exposes Europe itself to considerable danger, and it would be to the latter's interest if these immigrants were forced to observe laws imposing cleanliness, etc., from the moment that they commence their journey. Then, when finally the immigrant reaches his ship, he is stowed away in an over-crowded steerage, where the most unsanitary conditions prevail. The pilgrims to Mecca are not worse off than the steerage passengers to America; and the sanitary regulations of the pilgrim ships will be better in themselves and better applied than are those governing the steerage passengers to America. If considerable improvement in this respect is not enforced, the European Powers will be the losers, because quarantine will be imposed on ships arriving in America, and this will not only injure the passenger traffic but also the exportation of merchandise to the United States."

IN MEMORIAM.—JOEL SEAVERNS, M.D.

At a meeting of the Roxbury Society for Medical Improvement March 22, 1894, the following resolutions in regard to the late Dr. Joel Seaverns were passed:

Whereas, Through the wisdom of our Heavenly Father, our friend and associate, Dr. Joel Seaverns, has been called to a higher sphere of duty,

Resolved, That in the death of Dr. Seaverns this Society has lost one of its most valuable and honored members, and one whom we shall sadly miss at our meetings for medical improvement and social converse.

Resolved, That the Roxbury Society for Medical Improvement tender to Mrs. Seaverns and family, their cordial sympathy in the sad bereavement and loss of the dear and loving husband and kind and affectionate father.

Resolved, That a copy of these resolutions be forwarded to Mrs. Seaverns, by our Secretary, and that the same be inscribed on the records of the Society, and that a copy be published in the *Boston Medical and Surgical Journal*.

A. B. COFFIN, Secretary.

Correspondence.

AMERICAN MEDICAL ASSOCIATION.

SAN FRANCISCO MEETING.

SAN FRANCISCO, March 14, 1894.

MR. EDITOR:—San Francisco is a comparatively new city, but it is not lacking in places of interest to the visitor. About a half-mile to the northward of the city limits, nestling in a little valley and surrounded by evergreen trees, is the Presidio, the United States Army Station. A short distance beyond is old Fort Point, upon the water's very edge; the waves of the bay, dashing upon its cement abutments are broken into spray and lost upon its walls. McDowell Avenue leads from near the fort, around the top of the cliffs, overlooking the Golden Gate and the broad expanse of the Pacific Ocean. Vessels of all nations and descriptions can be seen in the offing or quietly gliding through the waters of the gate.

The Cliff House—a famous resort—is situated upon a promontory directly overlooking the ocean. In the distance, on a clear day, the Farallone Islands—twenty-five miles away—are seen rising abruptly from the water; while less than one hundred yards from where one stands, the Seal Rocks jut up from the waves and the loud barking of the seals and sea-lions upon them tells why they are so named.

Sutro Heights are just above the Cliff House. Here nature and art have so blended their works that the visitor is truly astonished and delighted with what he sees. The committee of arrangements are planning an entertainment at this place for the wives and daughters of visiting members of the Association. All San Francisco is justly proud of Golden Gate Park. What was once dreary sand dunes, has been transformed into a very garden, flowers bloom throughout the year, and the grasses are always green. Broad avenues wind in and out past the conservatory, the deer paddock, around the base of Strawberry Hill and on to the ocean beach.

The California Mid-Winter Fair is being held in the Park, at the base of Strawberry Hill, and occupies a space many acres in extent. This fair has an individuality peculiarly its own, and offers much of interest to every visitor.

R. H. PLUMMER, M.D.

Chairman Committee of Arrangements.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 18, 1894, TO MARCH 23, 1894.

So much of Par. 8, S. O. No. 60, March 12, 1894, from A. G. O. as relates to FIRST-LIEUT. HARLAN E. MCVAY, assistant surgeon, is amended to direct him, on being relieved from duty at San Carlos, Arizona, by FIRST-LIEUT. STRAUB, assistant surgeon, to report in person to the commanding officer, Fort Huachuca, instead of Whipple Barracks, Arizona Territory.

MAJOR HENRY M. CRONKHITE, surgeon, U. S. A., is relieved from duty at Fort Clark, Texas, and ordered to report in person to the commanding officer, Fort Reno, Oklahoma Territory, for duty at that post, relieving CAPTAIN WM. C. GORGAS, assistant surgeon.

CAPTAIN GORGAS, on being thus relieved, will report to the commanding officer, Fort Barrancas, Florida, for duty at that post, relieving FIRST-LIEUT. ROBERT S. WOODSON, assistant surgeon.

FIRST-LIEUT. ROBERT S. WOODSON, assistant surgeon, on being relieved by CAPTAIN GORGAS, will report in person to the commanding officer Fort McIntosh, Texas, for duty at that post and for field duty in the Department of Texas, relieving FIRST-LIEUT. BENJAMIN L. TEN EYCK, assistant surgeon.

FIRST-LIEUT. TEN EYCK, on being thus relieved, will report to the commanding officer, Fort Clark, Texas, for temporary duty at that post.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING MARCH 24, 1894.

B. S. MACKIE, surgeon, ordered to the U. S. Receiving-ship "Franklin."

W. C. BRAISTED, passed assistant surgeon, from Naval Hospital, New York, and to the U. S. S. "Columbia."

S. G. EVANS, passed assistant surgeon, from the Naval Hospital, Philadelphia, and to the Naval Hospital, New York.

W. G. FARWELL, surgeon, ordered to the U. S. S. "Columbia."

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE FOUR WEEKS ENDING MARCH 17, 1894.

FESSENDEN, C. S. D., surgeon. Detailed as chairman, Board for physical examination of Assistant Surgeon L. E. Cofer. March 6, 1894.

PURVIANCE, GEORGE, surgeon. Detailed as chairman, Board to inspect Reedy Island Quarantine. February 20, 1894. To report at Bureau for temporary duty. March 2, 1894.

HUTTON, W. H. H., surgeon. Detailed chairman, Board for physical examination of Inspector of Hulls. March 9, 1894.

GASSAWAY, J. M., surgeon. Detailed as recorder, Board for physical examination of Assistant Surgeon L. E. Cofer. March 6, 1894.

GODFREY, JOHN, surgeon. Detailed as chairman, Board for physical examination of candidates, Revenue Marine Service. March 6, 1894.

IRWIN, FAIRFAX, surgeon. To proceed to Paris, France, for special duty. February 24, 1894.

MEAD, F. W., surgeon. Detailed as chairman, Board for physical examination of candidates, Revenue Marine Service. March 10, 1894.

CARTER, H. R., surgeon. To report at Bureau for special duty. March 14, 1894.

BANKS, C. E., passed assistant surgeon. To proceed to Portsmouth, N. H., as inspector. March 12, 1894.

KALLOCH, P. C., passed assistant surgeon. Granted leave of absence for thirty days. March 12, 1894.

GLENNAN, A. H., passed assistant surgeon. Detailed as member, Board to inspect Reedy Island Quarantine. February 20, 1894.

WASDIN, EUGENE, passed assistant surgeon. Granted leave of absence for sixteen days. March 3, 1894.

KINYOUN, J. J., passed assistant surgeon. To report to chairman, Committee on Ventilation and Acoustics, House of Representatives, for special duty. February 21, 1894.

WOODWARD, R. M., passed assistant surgeon. To report at Bureau for special duty. March 14, 1894.

GUITERAS, G. M., passed assistant surgeon. Granted leave of absence for twenty days. February 19, 1894.

STIMPSON, W. G., assistant surgeon. Granted leave of absence for twenty-five days. March 5, 1894. Detailed as recorder, Board for physical examination of Inspector of Hulls. March 9, 1894.

HOUGHTON, E. R., assistant surgeon. Ordered to examination for promotion. March 3, 1894.

ROSENAU, M. J., assistant surgeon. Ordered to examination for promotion. March 6, 1894.

COFER, L. E., assistant surgeon. To report to Board for physical examination. March 6, 1894. Placed on "waiting orders." March 15, 1894.

GARDNER, C. H., assistant surgeon. Detailed as recorder, Board for physical examination of candidates, Revenue Marine Service. March 10, 1894.

STEWART, W. J. S., assistant surgeon. Detailed as recorder, Board for physical examination of candidates, Revenue Marine Service. March 10, 1894.

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—The annual meeting will be held at 19 Boylston Place, on Monday, April 2, 1894, at 8 o'clock.

Readers: Dr. C. H. Hare: "An Ovarian Dermoid Discharging through Bladder for Three Years before Operation and Cure." Discussion by Dr. W. H. Baker and Dr. W. F. Whitney.

Dr. Charles Harrington: "Massachusetts Laws Relating to the Sale of Foods; their Enforcement."

Election of officers for ensuing year.

Election of honorary and associate members.

Report of auditing committee.

JOHN C. MUNRO, M.D., Secretary.

THE SUFFOLK DISTRICT MEDICAL SOCIETY, SURGICAL SECTION.—The Surgical Section of the Suffolk District Medical Society will hold its regular monthly meeting at 19 Boylston Place on Wednesday evening, April 4, 1894.

Dr. E. W. Cushing will present a paper upon "Abdominal Drainage." Dr. M. H. Richardson and others will take part in the discussion.

Dr. F. G. Balch will report "Cases of Compound Fracture of the Ankle."

CHARLES L. SQUDDER, M.D., Secretary, 1 Marlborough St.

THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES.—The fifth annual meeting of the Association of American Medical Colleges will convene at Maple Hall, Grand Pacific Hotel, San Francisco, Cal., at 3 o'clock P. M., Wednesday, June 6, 1894. Action will be taken at this meeting upon several proposed amendments.

N. S. DAVIS, M.D., LL.D., President.

PERRY H. MILLARD, M.D., Secretary.

MEDICAL ASSOCIATION OF GEORGIA.—The forty-fifth annual session of the Medical Association of Georgia will meet in Atlanta, Ga., on April 18th, 19th, 20th.

W. H. ELLIOTT, M.D., President, Savannah, Ga.

DAN H. HOWELL, M.D., Secretary, Atlanta, Ga.

HARVARD MEDICAL SCHOOL.

EVENING LECTURES.

The next lecture will be given on Wednesday evening, April 4th, at 8 o'clock, by Dr. F. C. Knapp. Subject, "Traumatic Nervous Affections." Physicians are cordially invited.

RECENT DEATHS.

JOHN H. RAUCH, M.D., of Chicago, died suddenly in Lebanon, Penn., March 24th. He was a well-known authority on sanitation and medical education. He organized the Board of Health of Chicago, and was President and Secretary of the Illinois State Board of Health from its organization to 1891. He was a delegate to the International Medical Association at Berlin in 1890, and to the Pan-American Medical Congress in the City of Mexico. During the war he was brigade surgeon under General Augur, assistant medical director of the Army of the Potomac, and medical director of the Gulf Department of the Nineteenth Army Corps.

ERNEST HENRY JACOB, M.D., Professor of Pathology in Yorkshire College, died of acute arachnitis in Leeds, England, on February 28th, aged forty-four years.

AUGUSTE OLLIVIER, M.D., died recently in Paris, aged sixty-one years. He was a member of the Academy of Medicine and physician to the Vichy and St. Louis Hospitals, and to the Enfants Malades. His various writings have been of considerable value, especially his "Leçons Cliniques sur les Maladies des Enfants."

BOOKS AND PAMPHLETS RECEIVED.

Verbrechen und Walsinn beim Weibe, Statistische, Klinische und anthropologisch-biologische Untersuchungen. Von Dr. P. Nücke-Hubertsburg. Abdruck.

A Text-book of the Diseases of Women. By Henry J. Garrigue, A.M., M.D., Professor of Obstetrics in the New York Post-Graduate Medical School and Hospital, etc. Containing three hundred and ten engravings and colored plates. Philadelphia: W. B. Saunders. 1894.

Clinical Lectures on Pediatrics, delivered in the Vanderbilt Clinic during the Session of 1892-93. By A. Jacobi, M.D., Clinical Professor of the Diseases of Children in the College of Physicians and Surgeons of New York, etc. Stenographic reports. Reprint. 1893. New York: Bailey & Fairchild. 1893.

An Illustrated Encyclopædic Medical Dictionary, being a Dictionary of the Technical Terms Used by Writers on Medicine and the Collateral Sciences in the Latin, English, French and German Languages. By Frank P. Foster, M.D. Vol. IV, with illustrations. New York: D. Appleton & Co. 1894.

A Text-Book on Diseases of the Eye. By Henry D. Noyes, A.M., M.D., Professor of Ophthalmology and Otology in Bellevue Medical College, etc. Second and revised edition, illustrated by five chromo-lithograph plates, ten plates in black and colors, and 269 wood-engravings. New York: William Wood & Co. 1894.

First Aid in Illness and Injury, Comprised in a Series of Chapters on the Human Machine; Its Structure; Its Implements of Repair and the Accidents and Emergencies to Which it is Liable. By James E. Pilcher, M.D., Ph.D., Captain in the Medical Department of the United States Army. Revised edition with 176 illustrations. New York: Charles Scribner's Sons. 1894.

Original Articles.

EXERCISE IN THE TREATMENT OF LATERAL CURVATURE.¹

BY E. G. BRACKETT, M.D., BOSTON.

THE use of exercise is one of the means to be employed in the thorough treatment of lateral curvature, and varies in its object with the case, and character and degree of curve. It must be remembered that all degrees of severity are found, from those light postural cases in which there is no actual distortion, but in which the condition is one of malposition only and self-correction can be easily assumed, to those severe forms of fixed and rigid curves in which there is marked structural change both in the bone and in the softer parts, and in which no degree of force which can be borne by the patient is able to immediately bring about the full correction of the deformity. The treatment in the different cases will differ in the methods and the means employed; but the object of the treatment in all cases is essentially to increase the flexibility of the spine and the trunk, to hold the patient in a corrected position, and to improve the general muscular condition. The employment of exercise, in its object and in the method of its application, will vary necessarily according to the object of the treatment and the stage in which it is used. In most of the severer forms of lateral curvature, the most important element in the treatment is to increase the flexibility of the spine, to make a better attitude on the part of the patient possible. To attain this, obviously something more than exercise on the part of the patient is required, such as the mechanical correction, and in this stage of the treatment the use of exercise is an accessory part to this one of mechanical force. In the later treatment of lateral curvature the object of exercise is to improve the muscular condition, and to enable the patient to hold himself in a correct attitude. In those lighter forms in which the forcible correction is not necessary, the employment of exercise has a more prominent part.

The question of mechanical correction is not here considered. The employment of gymnastics will receive separate consideration, as to whether it is used as an aid to mechanical correction to increase the flexibility of the spine, or as a means of muscular training and development.

With reference to the character of the exercises, they may be classed as active and passive; the former including those in which treatment is performed purely by the aid of muscular exertion, aided only by the gravity of the body, and the second those in which this is either supplemented or substituted by additional force, used either by mechanical means or by an assistant.

The passive are included under the head of mechanical correction, and are, therefore, not considered here.

The active may be further classified with reference to the object for which they are used, whether for the increase of flexibility of the spinal column, or for the improvement of general muscular condition, and they will be considered under those heads.

Increase of Flexibility.—Exercises of this character have the same object as the passive mechanical correction, that is, the stretching of contracted structures in

such a way as to lessen the obstacles to correction of the deformity. These, in the main, consist of forcible bending and twisting of the spine in such ways that the force will be exerted against the distortion. Precaution is needed in this exercise that no such movements are employed which in any way tend to increase the flexibility of the spine in the direction of the concavity, and second, that all such motions are avoided which tend by themselves to the crowding together of the already distorted vertebral bodies, forcing them still further from the vertical line, and thus increasing the rotation which accompanies the lateral deviation. As the plane of the bodies of the vertebrae are carried farther away from the vertical line than is the axis of rotation, during flexion of the spinal column they are crowded together and are forced still farther away from the median line, thus increasing the rotation. This fact is made use of frequently in the examination, as when the patient is told to bend forward, which exaggerates the amount of rotation at first apparent. The opposite of this is equally true as seen in the diminution in the degree of rotary curve during suspension and during recumbency. In the same way that the pushing together of the vertebrae increases the rotation, the forcible stretching tends to pull them into the median line, and if this motion is carried still further by a backward bending, the force toward the correction of the rotation is still greater. For this reason all exercises which allow a forward bending of the spine are to be avoided, and those which tend to increase the backward flexibility should be encouraged.

Care is also necessary in those cases of double curve, that exercises directed toward the increase of the flexibility in one part of the spine shall not result in bending of the concavity in the other. Such particularly being the case with those asymmetrical movements in which the trunk is carried to one side, either in the standing position or by leaning over the side of a table or a roller. As the spine bends much more freely in the region of the concavity than of the convexity, unless great care is used when the effort is made, or when pressure is brought to bear upon the convexity of the curve, in all those motions where the whole trunk is involved the spine invariably moves more in the concavity than in the convexity. If this is allowed to happen, it obviously counteracts all the good that may come from the pressure or the force which may be used upon the convex portion.

This class of exercises is intended either to increase the backward flexibility of the spine and thus indirectly to improve the rotation, or is directed to the rotation itself. The first, or those for backward flexibility of the spine, are performed both when the patient is recumbent, and when the influence of the superincumbent weight is removed, and we have the force of muscular action only; and, second, those in which the patient is suspended, but in which we have not only a partial removal of superincumbent weight but also the force of direct traction; and, third, those in which the patient is standing, but in which either additional force or simply the weight of the body is used as a means to increase the amount of backward bending. The first of these are employed while the patient is lying prone, and the effort is made to forcibly raise the head and shoulders from the couch by muscular action alone. These are varied and made more forcible by bending backward over a padded surface, which is placed at the point where the greatest increase of amount of motion

¹ Read before the Boston Society for Medical Improvement, January 22, 1894.

is required while the patient is lying on the back, and allows the head and shoulders to fall downwards over the end of the couch. These are either done alone, or at first with the aid of an assistant in case the patient's strength is not sufficient.

In the second series of these exercises, in which the patient is suspended or partially suspended, the weight should be equally divided between the head and the arms, that is, the rope from the head-sling should pass over a single pulley and return to the handle which the patient grasps. If a compound pulley is used, then the amount of force used upon the head is relatively increased in proportion to the number of pulleys, and too great force upon the head and neck may be used. The object of the suspension is to exert a stretching force on the spinal column, and the suspension should be so performed that the force shall be expended as directly as possible on the contracted structures.

The third series consists of body movements, comprising bending and torsion of the trunk, and which bring the strain from the body weight and muscular action on the convexity of the distortion. These are taken in part alone, and in part with such assistance as will enable them to exert increased muscular action, as from straps and bars properly arranged for the direction of the pull, or by the hands of an assistant.

Exercises for the Improvement of the General Muscular Condition. — The object of exercise used with this purpose is to train the patient to maintain a more normal attitude, and by this training to make this position habitual. This is practicable only for those curves which have, by the other means, been made flexible and thus a corrected position possible, and in the light postural cases in which correction has always been possible. In the large majority of non-paralytic cases, the amount of asymmetry in strength is not great, at least not appreciable to practical tests; and for this reason special exercises for weak muscles do not play a prominent part. The matter of unequal use of muscles is one of greater importance; and such exercise is rather to the training of such use of the muscles, that the patient at first with effort can, and later will, maintain this corrected attitude without effort and unconsciously. The matter of aids to this by apparatus to prevent the patient from assuming injurious attitudes, both in standing and sitting, is important, but will not here be considered.

These exercises may be placed under three groups: (1) for correction of round shoulders; (2) for self-correction; (3) exercises in the corrected position. No attempt is made to enumerate the individual exercises used for these purposes, as this would open a subject of itself too large for the scope of this paper, but rather to consider the object of the various forms, and the conditions under which they may be used.

In the large majority of these cases of spinal distortion, there is found the condition of round shoulders, frequently associated with a pushing forward of the neck and head; and the early correction of this is important in thorough treatment. Like exercises that tend to increase a forward bending of the spine, the position of round shoulders exerts a force which is detrimental to the improvement of the rotation. When the curve and the rotation of the spine are in the upper part of the trunk, the forward movement of the shoulders tends to push backward the spine in such a way that the rotation of the vertebræ are increased. As the chest becomes more fully developed, and the

shoulders are carried and forced backward, the result is the same as in those exercises which tend to increase the backward flexibility of the spine. Many of these cases present a condition of decided rigidity, in which instance the treatment must be directed towards increasing the flexibility of the spine in this region, until correction becomes easy.

By exercise for self-correction is meant those movements in which the attempt is made by the patient's voluntary effort alone to assume a corrected position. In this, the patient may either stand erect, or be aided by such a position of the arms as will allow greater ease and more perfect correction, as, for instance, by the effort of the sense of raising and pushing with the shoulders or head, with the hands on the hips or clasped behind the neck; but no general rule can be laid down, as each case must be studied with reference to this by itself. In this effort, a marked improvement in the position is possible, while its value is manifest by the greater ease in assuming and maintaining this position, and, after practice, in the nearer approach to the complete correction. As an exercise this position is held for an increasing length of time during the regular hours of gymnastic work, and the effort made at all times during the day.

An additional force that can often be employed with very excellent results is gymnastic work in the corrected attitude. Bernard Roth has insisted on the value of maintaining this, which he has called the key-note position; and its value lies in its training one to perform body movements while the spine is held as far as possible in the corrected position. The key-note position may be one which has been found best through the effort of self-correction, or by the varied positions of the arms and the plane of the pelvis; or the exercises may be taken with the patient recumbent, and a more complete position of correction obtained by the addition of mechanical force pressure. The advantage of muscular work in the corrected position, maintained in any way, is obvious. After it has become easily possible to assume an attitude of self-correction, it is difficult to maintain the correction when any movement is attempted. By holding this position during gymnastic exercise, this same self-correction is maintained with greater ease during the day, and becomes more nearly habitual.

PATHOLOGY OF DIABETES MELLITUS.*

BY ELLIOTT P. JOSLIN, A.B., P.H.D.

(Concluded from No. 12, page 312.)

Experimental Work. — The experimental work of Herr von Mering and Herr Minkowski,⁸ on the production of diabetes by pancreatic extirpation, forms one of the foremost chapters in all experimental pathology. It is about two hundred years since Wirsung gave his name to the pancreatic duct. The pancreas must have excited a good deal of interest at that time, as we find Regnier de Graaf²² and Conrad Brunner²³ trying to extirpate it. They thought that their attempt was successful, and published two articles, in which the medical fraternity was informed in Latin that the removal of the pancreas was provocative of no results. Their word was accepted — or forgotten; and I find no further mention of the subject until Claude Bernard attempted to produce a diabetes by plugging the duct

* Read before the Boylston Medical Society of the Harvard Medical School, November 17, 1893.

of Wirsung, and failed. In 1889 von Mering and Minkowski began their work on the subject, to which they have added from time to time ever since. Many investigators have confirmed their work, but none have essentially added to it.

The technique of the removal of the pancreas is no mean piece of surgery. The gland is difficult to get at, the blood-supply is free, and it has an intimate connection with the surrounding parts. The total removal is essential for the success of the experiment, and it is in this particular that so many have failed. So carefully has Minkowski conducted his operations that in not a single instance did he leave even a small part of the pancreas in the abdomen. Peritonitis is one of the greatest bugbears to the operation. After full extirpation, first intention is seldom obtained, though this was obtained in partial removal of the gland. The experiments have been conducted on dogs. Cats are difficult to experiment upon, and the pancreas of rabbits cannot be successfully removed. Good results come from the extirpation in swine, but in birds and frogs the returns are not so satisfactory.

When a healthy dog is deprived of the pancreas he is attacked invariably within twenty-four hours with glycosuria, which continues for some weeks without interruption up to the death of the animal. On the first day after the operation the urine contains one per cent., or less, of sugar; on the following day the percentage has risen to four or six; and on the third day it has reached eight, ten, or even more. If no food is taken, the sugar begins to diminish; but after seven days of starvation it does not fully disappear. The amount of sugar decreases when the animal becomes very weak, and at some time before death may wholly disappear from the urine. In two of Minkowski's cases this occurred. "The diminution in the amount of sugar excreted in no way corresponds to an improvement, but rather to a worse state of the conditions of nutrition." Peritonitis and septic processes may lead to a disappearance of the sugar. If carbohydrates are taken, the amount of sugar rises rapidly, and the sugar ingested is practically wholly excreted. The urea stands to the sugar in the ratio of two to three, when the dog is on a pure flesh diet; and this ratio is maintained with very slight variations through all the vicissitudes of the experiment. Thirst, polyphagia and polyuria are constant accompaniments of the glycosuria; and the emaciation, feebleness and the slow healing of the wound all show that the animal is suffering from a severe diabetes mellitus.

Von Mering and Minkowski have further reported that after a partial extirpation of the pancreas a diabetes was not produced. To this fact they attach much importance. They think this explains the non-appearance of glycosuria in man in some pancreatic lesions. A part of the gland can perform the function of the whole. Furthermore, this answers the objection which has been raised that the diabetes was due to nerve lesions caused in the operation. In the removal of a large portion of the gland, for example, four-fifths, the same nerve lesions would be committed as in the removal of the whole gland. Just how much of the gland must be left in the abdomen to prevent diabetes cannot definitely be stated. The nutrition of the part left behind here enters into the problem. In some of the instances where a portion of the gland is removed, a diabetes of light grade is produced. This is present only when the animal is on a carbohydrate diet; and

it is supposed that slight glycosurias in man might be attributable to some moderate disturbance of the pancreatic function.

The abdominal grafts of the pancreas are by far the most striking part of Minkowski's and von Mering's work. This was suggested by Schiff's work on the thyroid. The art of the experimenter is here given full range. The pancreas is a fragile organ and quickly dies. Moreover, an animal which has submitted to an operation on the gland is in great danger of peritonitis. Both obstacles were overcome in the following manner. The pancreas was carefully dissected from its attachments in the abdominal cavity, turned on its axis and stitched to the abdominal wall. The blood-supply was disturbed as little as possible. The wound was allowed to heal, and gradually the pancreas became engrafted on its new surroundings. When this was firmly established the dog was submitted to another operation, in which the internal part of the gland was removed. On the recovery of the animal no diabetes resulted. After an interval of some time, the engrafted pancreas was removed; and when this was done, diabetes in all its forms appeared. What more striking proof could be asked for the action of the pancreas in producing diabetes?

The removal of the graft with its sequence of diabetes throws aside completely the theory that in these cases nerve lesions are the cause of the disease. The blood-supply of the graft, in some cases from the abdominal parietes, in others from the aorta alone, excludes any theory which ascribes the prevention of the diabetes to the different blood-supply the gland might receive.

No connection exists between the intestinal secretion of the gland and its functions in the prevention of glycosuria. Minkowski has observed the absence of the ordinary secretion and yet no diabetes, while Thiroloix²⁴ has seen a diabetes come on when the secretion was active.

Is this function whose disturbance leads to the production of diabetes a specific property of the pancreas?

Minkowski concludes that it is, else why should diabetes appear on its extirpation? Various authors have thought differently. Renzi and Reale²⁵ found sugar in the urine after the removal of the salivary glands. Minkowski has carefully gone over their work in his own laboratory and finds (1) that the glycosuria was usually slight in intensity, (2) that it was transitory, and (3) that it was not even a constant result of such extirpation. And as for the work of the same authors on duodenal extirpation, much the same conclusions were reached which Weintraud²⁶ has further confirmed.

Falkenberg, after removal of the thyroid, obtained a glycosuria in 13 out of 20 cases. Gley²⁶ and Minkowski agree in thinking this glycosuria due to traumatism.

It may be well to definitely state that the removal of the gland so that all intestinal secretion is cut off brings on no diabetes. A transitory glycosuria may result from the abdominal operation.

Minkowski's experiments of total extirpation, partial extirpation and grafts of the pancreas have been confirmed by Hedon,²⁷ Thiroloix²⁸ and Abelman.²⁹ Lepine³⁰ in 100 pancreatic extirpations, and Sandmeyer³⁰ in 29, have come to the same result.

How does removal of the pancreas cause diabetes mellitus?

Minkowski does not say, but simply states the two

theories which are advanced, and points out that there are further channels for experimental work which when traversed will enable us to have a clearer insight into the question.

The first of the two theories at present most advocated is that there is a ferment in the blood which destroys the sugar. This ferment is furnished by the pancreas, disease or removal of which causes a heaping up of the sugar in the blood, due to the non-assimilation of the sugar by the tissues. The other theory implies a poison in the blood, which in the normal person is destroyed or rendered inactive by the pancreas; removal of this gland allows an accumulation of the poison and grave nutritional disturbances.

Lepine²¹ was a fellow-worker with Dr. H. P. Bowditch, who has spoken highly of him to me as a scientist. He discovered that the normal pancreas when treated with a little water made alkaline was able to destroy a small quantity of sugar. The blood of an animal deprived of its pancreas lost less sugar than the blood of a sound animal; and hence Lepine concluded that the pancreas yielded to the blood a ferment which contributed powerfully to the destruction of the blood sugar. This ferment he called the glycolytic ferment. He found that the blood of the portal vein was richer in this ferment than that of any other part of the body, and after an elaborate series of experiments proved that this ferment was contained in the white blood-corpuscles. This ferment is diminished, he has shown, in the blood of diabetic persons to the number of seven; and, in fact, in all cases in which there is an increased amount of sugar in the blood the ferment is present in less than the normal quantity.

Writers on diabetes speak favorably of Lepine's theory, but most of the experimenters have not yet accepted it. This theory of Lepine's necessitates the view that glycosuria results from the lack of the power of assimilation of the sugar by the body. Hedon²² and Seegan²³ also consider that the lack of assimilation of the sugar is the cause of diabetes.

RECENT WORK OF CHAUVEAU.²⁴

Chauveau was a fellow experimenter with Claude-Bernard. He has done much eminent work in time past, and the field of experimental diabetes is well known to him. Two articles which he has recently published connect the work of Claude-Bernard and that of Minkowski. In his first memoir he proves that diabetes is due to an increased production of sugar by the liver. In a normal animal the blood in the hepatic veins contains the most sugar of any blood in the body. The sugar in the arterial blood always is greater in amount than that in the venous. Claude-Bernard has shown the formation of this sugar to be the property of the liver, and Chauveau has made clear that the destruction of the sugar takes place in the tissues. Somewhere in the capillaries between the red arterial and dark venous blood the sugar is lost. If this sugar continues to be lost in an animal rendered diabetic, we can feel sure that the cause of the diabetes rests on the overproduction of sugar and not on its lack or destruction.

So Chauveau produced diabetes in animals by traumatism, by puncture of the fourth ventricle, by section of the cord just below the medulla and by removal of the pancreas. In each instance the analysis of the arterial and venous blood showed the normal excess of

sugar in the former. It is well known that a section of the spinal cord from the last few cervical to the sixth dorsal vertebræ produces a diminished amount of sugar in the blood; but when this section was made, the arterial remained richer in sugar than the venous blood. His experiments confirmed his theory that diabetes is due to an increased production of sugar. This work was preliminary to his next article.

We know that sugar is formed in the liver. Is it formed anywhere else? The muscles remove the sugar from the blood, which they use dehydrated in the form of glycogen. There is no reason why these, like the liver, should not convert this glycogen back into sugar, but no proof of this has ever been given. Furthermore, if the muscles did do this, we should expect to find more sugar in the venous blood than in the arterial, but Chauveau's previous work has shown that this is not so. The liver, then, is the source of the increased sugar in the blood—hypoglycémie—in diabetes; and if we can explain the mechanism by which the liver brings this about, we can explain the disease.

For a long time it has been known that puncture of the fourth ventricle would produce a passing glycosuria, and lately von Mering and Minkowski have shown that removal of the pancreas will cause the same result. Various clinical facts also go to show that the pancreas is connected with the production of diabetes. And this leads us to consider the pancreas in a new light as a moderator of the glycaemic function of the liver. Now in diabetes there is besides the glycaemia a destruction of the tissues going on throughout the entire body. The losses of the body surpass its gains. Katabolism is the ruling feature, and from the products resulting from the katabolism part of the sugar is formed in the liver. This we know because diabetic animals which are starved still continue to secrete sugar. But how does the pancreas act to prevent this destruction of tissue and subsequent formation of sugar in the normal state? As the veins of the pancreas empty into the vena porta, it is natural to explain this influence of the pancreas upon the formation of sugar in the liver by supposing an internal secretion of the gland which empties into the blood, by which it is carried to the liver and participates in its functions. However, as yet experiment has given no proof of the direct action of this pancreatic secretion on the liver. The facts already known, with what Chauveau adds later, tend to show that this action is through the agency of the nervous system.

The functions exercised by these two glands depend without doubt upon their inherent properties, but the nervous system cannot fail to regulate their action. Glands have been shown to have excito-secretory nerves—compare the submaxillary gland and the chorda tympani—and there is no reason to suppose that the pancreas and the liver are exceptions. In fact the teachings of physiology would impose upon us the consideration of the existence of excito-secretory and inhibito-secretory nerves of the liver. Indeed, study of nervous action on the liver has been made; but Chauveau combines the former experiments with pancreatic extirpation.

When a section of the spinal cord at its junction with the medulla was made on starving dogs, hypoglycémie resulted as after the extirpation of the pancreas and this hypoglycémie was attended with glycosuria. These common symptoms lead us to draw a

connection between the result obtained on bulbar section and pancreatic extirpation, and to conclude that in both instances the animal is subjected to the same influence; in one, pancreatic secretion is rendered impossible by removal of the pancreas; in the other, it is made quite as impossible by paralysis of the gland. From the effects thus produced by bulbar section we can conclude that the pancreas is thereby isolated from its excito-secretory centre, whence suppression of the internal secretion and subsequent hypoglycémie. But this section did not injure the excito-secretory centre of the liver; on the contrary, it became more active, which would imply that it was not antagonized. The following deductions then can be drawn from bulbar section: (1) the action of the pancreas on the glucose-forming function of the liver appears to be under the control of a centre which excites the internal secretion of the pancreas; (2) this centre is situated at some point above the junction of the cord and medulla; (3) the sugar-forming function of the liver is controlled by an excito-secretory centre which is situated in some region of the spinal cord; (4) the action of the pancreas upon the liver is exercised upon the excito-secretory centre of the liver and not on the liver itself.

Puncture of the fourth ventricle causes much the same train of phenomena as does the section of the cord at its junction with the medulla. In bulbar section the animal of course dies because his life is dependent on artificial respiration. In medullary puncture respiration is not disturbed. The identity of the results leads us to consider that in sugar-puncture of the fourth ventricle the excito-secretory function of the pancreas is for the time deranged. This leads up to the conclusion that this centre is no higher up in the nervous system than the medulla, and the section between the spinal cord and medulla has shown that it is no lower.

This production of glycosuria by bulbar section can also be explained on the hypothesis that there is an inhibito-secretory centre of the liver in the medulla, which by the operation is shut off from its influence on the liver. The internal secretion of the pancreas then would stimulate the inhibito-secretory centre and moderate the excito-secretory, while its absence would produce just the opposite results and hypoglycémie would appear. The lighter glycosuria which appears on bulbar section could then be explained by the pancreas acting to a slight extent, though removed from its excito-secretory centre. Having thus set forth the theory, Chauveau proceeds to the more original part of his work.

When a section of the cord is made between the fourth cervical and sixth dorsal pairs of nerves, a hypoglycémie is produced. Evidently this is due either to increased action of the inhibitory centre or paralysis of the excitatory. The second alternative conforms more easily to the facts. Now as this paralytic effect ceases when we go above the fourth cervical pair, and we then get hypoglycémie, it is evident that the excito-secretory centre of the liver is in the neighborhood of the fourth cervical pair. The section between the fourth pair cervical and sixth pair dorsal is then explained by this section severing the communication of the excito-secretory centre with the liver. It can furthermore be deduced that the inhibitory fibres of the liver pass out of the cord above the fourth, or else the hypoglycémie would not result from section below that point.

When a section between the fourth cervical and sixth dorsal is followed by removal of the pancreas, instead of getting a hypoglycémie with the symptoms of diabetes which are ordinarily obtained on removal of the pancreas, Chauveau found a condition of hypoglycémie, and following the theory as detailed above, the explanation is easy. The connection between the liver and its excito-secretory centre having been severed, the removal of the pancreas could not produce its ordinary effects.

When suppression of the pancreas is followed by section of the cord between the fourth cervical and sixth dorsal, from the previous work we should expect that the symptoms of diabetes would cease when the latter part of the operation was performed; but no such result awaits the experimenter. The hypoglycémie continues. The reason can be found in the sympathetic ganglia which lie in the track of the nerves. These act as relays to the central nervous system; and from these nervous impulses are sent forth, only these are dependent in character upon the primary impulse which is received from the higher source. They continue to act in the same way even though separated from their centres in the central nervous system. So when the cord was cut between the fourth cervical and sixth dorsal, the ganglia were left under the control of the inhibitory centre, and subsequent removal of the pancreas had no effect.

These experiments are further varied by substituting the bulbar section for removal of the pancreas, and the same results are obtained. Thus, section of the cord between the fourth cervical and sixth dorsal, followed by section at juncture of medulla and cord, produces no hypoglycémie. The hypoglycémie is produced and not diminished, however, when the section below the medulla is followed by section of the cord between the fourth cervical and sixth dorsal. Thus, in these experiments the isolation of the excito-secretory centre of the pancreas (or what we can consider as connected with it, the inhibito-secretory centre of the liver) acts in the same way as does removal of the gland itself. A section just below the medulla, combined with removal of the pancreas, makes no greater hypoglycémie than does simple removal of the gland.

To recapitulate Chauveau's theory: Diabetes is due to an excessive production of sugar by the liver. This production is regulated by the internal secretion of the pancreas, which acts upon the liver through its excito-secretory and inhibito-secretory nerves. The excito-secretory centre is in the cord near the origin of the fourth cervical pair. The inhibito-secretory centre is in the medulla. The internal secretion of the pancreas acts on these so as to stimulate the inhibito-secretory centre and moderate the excito-secretory centre. Removal of the pancreas does the reverse, and brings on hypoglycémie. Section just below the medulla cuts off the action of the inhibitory centre, and hypoglycémie results. Section of the cord between the fourth cervical and sixth dorsal allows the inhibito-secretory but not the excito-secretory centre to act — whence hypoglycémie. These centres act through ganglia, which, once excited, keep on originating impulses of a similar nature unless they receive an excitation of an opposite character. The removal of the pancreas has the same action on these ganglia as does the section at the junction of the cord and medulla. "The close connection between the effects of depauperization and

those of bulbar section serve to establish the identity of the direct mechanism which presides over the manifestation of these effects. The pancreas plays the rôle of an inhibitor of the liver by means of its central nervous regulators."

This theory of Chauveau's, which I have not stated quite as fully as the author gives it, calls our attention to the unity of diabetes. It is complicated. It is based on analyses of the blood and experiments on the nervous system, both of which methods of experimentation give opportunity for error. Nevertheless, it furnishes a better explanation of all forms of diabetes than anything yet advanced and will be useful in suggesting further work.

RELAXATION AS A CURATIVE AGENT.

BY ANNIE PAYSON CALL, BOSTON.

MANY diseases are either caused by or accompanied with unnecessary tension, and in addition it might be said that many diseases cause tension. This tension, which is involuntary but can be voluntarily dropped, disturbs the natural equilibrium of the forces of the body, and will not allow Nature to do her perfect work. The antidote is relaxation; and this being the case, certainly relaxation is not given the place that should be accorded to it among the natural curatives. Neither is it yet recognized to be as effectual an aid to the better working of medicine, as exercise, fresh air, nourishment, and so-called rest, which is often very far from relaxation. These four are accepted natural curatives; but their good effects may be greatly enhanced by systematic relaxation, which renders the body more susceptible to their influence.

Take the simple instance of severe pain, which of itself directly excites contraction. A very slight effort of the will to relax the suffering part often brings almost immediate relief. It is because of their relaxing power that warm applications are made. If these in return were assisted by the natural voluntary relaxing of the patient, each might help the other greatly and save much unnecessary suffering. With severe pain contraction is so abnormally instinctive that it seems at times to relieve it, but after such relief there is always a reaction which means increased suffering.

Many forms of indigestion result from contraction, and nothing else, and it is marvellous that medicine should have any effect in such cases, when it is steadily thwarted by an extreme tension on the part of the patient, a tension which might be dropped voluntarily.

Of course indigestion of this sort can become chronic, when the tension is continued long enough to get beyond medicine or natural cures.

The semi-invalids who come week after week for more medicine and expect it to do its work and cure while they are steadily resisting it, are familiar occupants of a physician's office. But it does not, apparently, occur either to the patient or the physician that the patient can be taught not to resist, by as normal a process as a child is taught the use of its fingers on the violin—or the voice is given its natural freedom, that it may express itself in song.

It is an almost equally familiar fact that there are invalids, so-called, in whom the original disease has entirely disappeared, but the brain impression is almost, if not quite as strong as during the disease, and the patient is ignorant of the fact that he has recovered. The disease habits here often take some form of tension, the dropping of which helps the patient to reach a normal state, although there must be at the same time some mental effort.

Nervous tension is often so immediately connected with some mental impression that in order to relieve it the greatest tact is required. For instance, you cannot say to a man, "My dear sir, you are quite well if you will only behave as if you were." That would throw him back more decidedly upon the sick-list; but you can lead him little by little until he sees the state of his own case, believing this to be entirely his own discovery, and so takes pleasure in removing all abnormal habits and curing himself.

So it is with many cases of nerve trouble which arise from an over-worked, over-excited, or over-anxious brain. One form after another of mental strain the patient *must remove himself* before he can really begin to get rid of the tension that is keeping him ill. The triviality of these nervous anxieties is most remarkable, but of course they should be looked upon as mere forms of tension and dropped, just as one might study a muscle that is unnecessarily contracted and train it to a natural freedom. On the other hand, their triviality can never be truly impressed upon the patient unless he is led to discover it himself. A blunt effort at persuasion merely increases the tension, and this same tension, of course, retards the recovery.

A nervous invalid of this sort should be trained always objectively, as far as possible. Without such training, a man, or more especially, a woman, may be kept ill unnecessarily long, through the action and reaction of an anxious mind and tired nerves. The anxiety seems real and so works upon the tired nerves. The tired nerves are a physical reality and not only increase the anxiety but, in nine cases out of ten, cause it. The tension is continued and the patient is kept ill, and neither fresh air, exercise, nourishment, sleep, nor medicine can help a man, to any extent, where his own will persists in permitting his abnormally anxious brain and tired nerves to play back and forth one upon the other. This condition is more common with women than with men. Some women seem to take pleasure in overloading and emphasizing their anxious brains, in lacerating their tired nerves and then taking a daily, almost hourly, unhealthy observation of both. This, of course, is due to the more sensitive nervous temperament of the woman. But it is like rubbing a wound and then expecting it to heal, or perhaps in this case there is even a grim enjoyment of the non-healing process. And all so unnecessary if one would learn to

look the other way, while nourishment, fresh air, exercise, sleep, and a normal relaxation are doing their own work with the assistance of whatever medicine may be needed.

Beside this nervous fatigue, there are many forms of nervous contraction from apparently no immediate organic cause, which might be greatly helped by gaining the power to relax normally. As an instance may be given a case of a woman who had suffered for years from an inability to articulate clearly and a want of power to direct her muscles. She could not make herself understood by any one, and at times would fall full length upon the floor, so uncertain was her balance. Physicians had told her that there was no cure, and after thirty years of this unfortunate state, she has now learned not only to balance herself on both feet, but to stand and rest easily upon one, and has gained the power of communicating with others with a perfect articulation.

The fact of the possibility of dropping unnecessary tension seems to be little recognized by many physicians. A short time since a very prominent doctor in one of our large cities, informed a man who applied to him for help in a spasmodic contraction of the throat, that he could not help him in any way: but added, "Nothing worse will happen than that you will faint away, and you will be all right then, for your throat will relax." It never occurred to him that the man, who had an excitable, nervous temperament, somewhat over-strained, might learn to relax his own throat, and save the inconvenient relief of fainting at times for the purpose of regaining his breath.

Unnecessary contraction, while more immediately recognized in such cases as the above, may be found, although by no means to so great an extent, in many diseases that have not a directly nervous cause. Various forms of congestion are accompanied with contraction. Fever may be increased by an excitement which causes contraction, and decreased by quietly giving up to it and letting it have its way. And so one form of disease after another could be named, which is increased by the accompanying contraction and would be correspondingly abated by its removal.

With unnecessary contraction, nourishment has not its full effect, the digestion is labored, so that nervous force is used in the process of digestion which would otherwise be kept for new life. Fresh air has not its full reviving effect, for the circulation is impeded, and the blood cannot carry the oxygen so freely through the body. Vigorous exercise is not taken as easily when the muscles are not normally directed, neither is it as beneficial in its results. First, because of the waste of force in motion; second, because as a result of this waste, there is often more or less tension when resting, which does not allow the quickened circulation all the freedom required for its best result. With unnecessary tension, sleep is not so restful as it should be, for when one does not give way to a perfectly natural sleep, the waste cannot be supplied so rapidly. Where it should be all a building up, there is at the same time a using up of force, all the more trying because it is abnormal.

Fresh air, exercise, nourishment and sleep are Nature's curatives. To lead the patient to a greater freedom is only to open the way that these may have a more immediate effect. The freer the body, the quicker Nature can bring it to a state of health, whatever may have been wrong in the beginning, and this, of course, applies equally to the action of medicine.

A man takes ether not only to get relief from pain, but to be kept in a passive state which will enable the surgeon to do his work, unhampered by the contractions that would inevitably come from fear or pain.

There is no ether that will keep a sick man in a state of freedom and allow the disease to run its course and be over with, but there is a natural freedom which might come without ether if the patient had a little knowledge of how to gain it.

A disease has a natural course, even though it is a disease, so truly does order reign in spite of man's disorder, and to give it its freedom with the guide of the curatives, would lessen the possibility of after effects which are often worse than the disease, or of death itself.

It is, of course, impossible to train a very sick man to keep quiet and free and let the disease be taken care of by Nature and medicine, but it is quite possible to train one who is not very ill, so that he may be saved much unnecessary suffering. Even a very sick man, if he is in his right mind, may be helped by gentle and constant suggestion.

Of course, as a preventive, a training to natural freedom could be used illimitably, but the object of this article is only to call attention to its curative power. A sense of weight may be given to the whole body, through getting the impression of weight from the slow lifting of an arm — either by another's moving it gently so that it must gradually be passive, or by the patient's being taught to lift it himself from the shoulder — even an inch from the bed, and then dropping it. As this is repeated over and over, the impression grows and a greater sense of weight is spread over the whole body, which relieves the tension and gives a certain degree of freedom. In addition to this, is the quiet effect upon the brain, which comes from fixing the mind upon something so simple. The result of the idea of weight tends to spread the freedom over the entire body, unconsciously to the patient.

Great care must be taken that the sense of weight is weight alone and not pressure.

This same result sometimes comes more quickly by a very slow lifting of the head by the two hands of another. The extremely slow motion of head, legs, or arms always has a directly quieting influence and so leads to greater freedom.

The immediate effect upon the brain of breathing is very well known, and various forms of quiet, long, and short breaths, can be made most useful, especially if the patient is well enough for the simple concentration of counting, — for instance, inhale counting seven, exhale counting seven — rest (breathing naturally) counting seven — and repeat this seven times keeping his own count. This may be increased to nine, twelve, fifteen, twenty-four, and the resting periods may be doubly as long as the breathing.

This simple concentration is often difficult even for those who call themselves well, and is most useful in focussing the mind with many who have, or have had, nervous prostration. A return, after a long nervous illness, to a natural use of the mind in talking, in reading, or in the various daily affairs of life, is often difficult, when otherwise one might be perfectly well, and is made easier by this simple form of concentration in breathing, because through it the brain gets a better balance. Added to these, are other exercises in concentration, by which, through keeping the mind steadily for a very short time on various forms and motions of

nature, a strong brain impression is made and a healthier state of nerve brought about. These must be chosen with care and with special reference to individual needs, and are meant, of course, for help in nervous cases. They are successful often where the interest needs to be roused, and help comes as much from the way the exercise is given as from the exercise itself.

Having given an idea of weight and the deep breathing exercise according to the state of the patient, more or less can always be done in helping the power of direction, so that only the muscles needed will be used, even in turning over in bed or moving an arm or leg. Very great help is given through conveying an idea of what it is to free one's self from unnecessary mental tension.

Take a case, for instance, in which the patient is resisting constantly in his mind the fact of being ill. This resistance produces a tension of the brain, the effect of which is felt upon the entire body. Now if he can be shown, quite simply, that he must be perfectly willing to be ill, for that *will help him most to get well*, there is a counteracting effect at once and Nature and the doctor are given a better chance.

To be sure there are often instances where the patient instead of resisting the illness gives up to it too willingly. In that case he is resisting recovery and must no more be permitted to do so than to resist the illness. *Relaxation is necessary only in so far as it trains the body to a normal freedom and so enables it to find and hold its own equilibrium.*

It may be thought to be impossible to change a man's mental state to such a degree, but that depends upon how it is approached. As has been said before, all the tact of a diplomatist must be used in such training, as indeed in all training for a natural freedom.

The same is true of the resistance to various annoyances, great and small. Indeed irritability is one of the most fruitful causes of prolonging disease. The unwillingness in each case has the same effect upon the brain, and its counteraction brings immediate relief and so opens the way for a more rapid cure.

The process of relaxation as a curative may be briefly summed up thus: a greater freedom of the body to be gained through obtaining a sense of weight, quiet and deep breathing, and a power of natural direction and simple concentration.

It results in a freeing of the body, which will more certainly and rapidly permit a wholesome effect from fresh air, exercise, nourishment, sleep, medicine, and other curative processes.

Clinical Department.

TWO CASES OF PULMONARY CONGESTION AND OEDEMA OCCURRING DURING PREGNANCY.¹

BY FRANCIS W. GOSS, M.D., ROXBURY, MASS.

CASE I. Acute pulmonary congestion and oedema in patient six and one-half months pregnant. Death.

At 2 A. M., March 27, 1889, I was called to see Mrs. D., six and one-half months advanced in her first pregnancy. She had recently moved to Roxbury from a distant part of the city. Her pregnancy had been uneventful till the present illness.

¹ Read before the Boston Society for Medical Improvement, January 22, 1894.

During the afternoon preceding my summons she had been to see her physician, three or four miles away, because of a slight cough, and some difficulty of breathing, which had troubled her for a day or two. She retired as usual, slept for several hours, and then woke suffering from great dyspnoea and distressing cough. When I reached her she was sitting in a chair, in extreme distress, with alarming dyspnoea, rapid breathing, coughing and expectorating quantities of bloody serum. Her face was dusky, skin cold, and bathed with clammy perspiration. Her pulse was very rapid and feeble; the lungs filled with moist râles, and her condition betokened impending death. She lived but a short time, — not more than half an hour after my arrival.

Her physician informed me that there was nothing apparently serious in her condition when she called upon him the previous afternoon, and he was much surprised at her sudden decease.

CASE II. Sudden pulmonary congestion and oedema in patient six and one-half months pregnant. Induced labor. Recovery.

Mrs. M., six and one-half months advanced in her seventh pregnancy summoned me at 11 P. M., October 26, 1893, on account of severe dyspnoea.

She had been seen nine days before by Dr. G. W. Clement in a similar attack, when her husband came for him saying that he believed his wife was "choking to death." Dr. Clement informs me that he found her sitting in a chair, bent forward, coughing hard and raising bloody, frothy sputa. The chest was filled with moist râles, the pulse was quick and feeble, and her condition critical. He was with her some three hours before she was sufficiently relieved for him to feel that it was safe to leave her. She rallied under the use of stimulants and of pilocarpin *sub cut.* On subsequent examination he found a mitral systolic murmur of the heart, and albuminuria.

Being obliged to leave the city for several days Dr. Clement directed that I should be sent for during his absence, if there was need.

When first seen by me the patient was suffering from alarming dyspnoea and orthopnoea, frequent cough and expectoration of bloody sputa. Pulse 120, respiration 48. In about two hours, under the use of aromatic spirits of ammonia, nitro-glycerine, etc., she became easier, and I left her for the night.

October 27th. She was much more comfortable, and had slept somewhat. She reported an attack of acute rheumatism several years ago, and another last winter.

Examination of the heart showed marked mitral systolic souffle; not much enlargement of the organ. Some oedema of extremities. Urine abundant under the use of diuretics prescribed by Dr. Clement. Albumen, one-third bulk. Epithelial and granular casts.

The patient said that she had not felt any foetal movements since the attack of dyspnoea ten days ago. No foetal heart heard on auscultation. She has had two premature births of dead children at about seven months, since birth of last living child four and one-half years ago.

October 29th. Has had some return of the paroxysms of dyspnoea. In view of the recurrence of the attacks and the continued tendency thereto, and the cardiac and renal disease, it seemed to me that the patient's condition was critical so long as the foetus remained in utero. Accordingly, under antiseptic precautions, I introduced a catheter through the cervix

uteri, with the view of bringing on premature labor. Pains came on during the evening and at 12.20 A. M. October 30th she was delivered of a fœtus apparently of about six and one-half months' development which had evidently been dead for several days.

With the exception of some rise of temperature on the second day, for which an antiseptic intra-uterine douche was given with immediate improvement, the patient made a satisfactory recovery.

November 30th. The patient is about and doing house-work. Feels fairly strong; no return of dyspnoea since labor. Urine abundant; specific gravity 1.025; albumen small in amount; and but one granular cast found in examination of two slides.

Judging by what I can learn from the text-books, and from conversations with physicians, such cases as those here reported are fortunately rare. When they occur, and medicinal treatment does not relieve, it seems to me the only hope for the patient may be speedy delivery, if it can be effected. In the first case there was no opportunity for the procedure. In the second, the patient's life was in jeopardy as shown by the recurrence of the alarming attack, notwithstanding she was under the influence of digitalis, diuretics, cathartics, etc., prescribed by Dr. Clement.

Whether such conditions appearing in pregnant women are always accompanied by cardiac or renal disease, or by both, I do not know. These troubles were present in the second case. In the first the point was not determined.

TOXIC EFFECTS AFTER USE OF OIL MALE FERN (ETHEREAL) FOR TAPEWORM.

BY JOHN H. GRANT, M.D., FORT PORTER, BUFFALO, N. Y.,
Hospital Steward, U. S. Army.

C. H., aged thirty-five, was a soldier in the Garza campaign on the lower Rio Grande in Texas during the winter of 1890-91, at which time he was often obliged to subsist in part on insufficiently cooked goat meat. As a result, he became the possessor of a *tænia saginata*. Outside of the few large towns in this part of Texas, defecation by the inhabitants (principally so-called *greasers*) is universally carried on in the open-air and readily accounts for the manner in which our patient became infected.

In 1892, an army surgeon treated him by the administration of oil of turpentine, which produced violent strangury and the passage of about sixteen feet of the worm.

In November last he was again treated with drachm doses of oil male fern (ethereal) (of an old stock some time on hand); but two doses were retained, aborting about eighteen feet of the entosoa.

March 1st the man requested further treatment; and a fresh supply of the male fern having been received (W. H. Schiefflin & Co., New York), an emulsion with acacia was prepared, each fluid ounce containing one and one-third drachms of the oil. The day previous the patient abstained from solid food, a saline cathartic being administered at sunset. The morning following, at 6.30 one ounce of the mixture was given, and at 8.30 a like quantity; at noon a dose of sal rochelle was taken, resulting in the expulsion of about eighteen feet of the parasite. About 4 o'clock the patient, on leaving the water-closet, fell to the floor and had to be carried to his bed. The writer being

then called, found the patient in a most pitiable condition — almost pulseless, skin cold, eyeballs protruding and staring, suffused with tears, the lids puffed and of a dark-brown color. Deafness was nearly complete in both ears, but the sight was not at this time affected. Patient was husky, suffered from a vise-like constriction of the chest, gasping for breath, and with a ghastly expression of despair. He appeared to be *in extremis*. As soon as possible whiskey (one ounce) was administered, and a sinapism applied over the sternum. In about five minutes the pulse could be felt. The other symptoms gradually disappeared, so much so, that in a half hour the case was considered safe. The feeling of chest constriction and of burning within the stomach lasted for a few hours; but a few ounces of milk and whiskey and particles of ice freely dissolved in the mouth, soon gave relief. The patient had dimness of vision and was very weak and nervous the day following, keeping his bed for two days.

There were two interesting points about this case. The first was the extreme depressant action of the male fern in what might be considered not a large dose.¹ It will be noticed that it was nearly eight hours after the second and last dose in this case before any alarming symptoms presented, and not until after the bowels had been moved several times. The second point was the thrice-repeated failure to bring away the head. Diligent search in the present instance failed to discover any traces, although a portion of the voided parasite was very narrow. Possibly the head is very securely imbedded beneath a fold of the *valvula conniventes* and protected from the direct action of the drug. The peristaltic action of castor oil might have secured the head, but owing to the disgust excited by it in the patient on previous attempts, an alkaline cathartic was prescribed instead.

Medical Progress.

RECENT PROGRESS IN PUBLIC HYGIENE AND PREVENTIVE MEDICINE.

BY SAMUEL W. ABBOTT, M.D.

INFECTIOUS DISEASES, AND THEIR PREVENTION.

Diphtheria. — Dr. Thorne Thorne, chief medical officer of the Local Government Board of England, in a recent lecture upon Diphtheria, said:

"Bad sanitary conditions might have an influence, but they are overwhelmed by other conditions which cause the disease. . . . Diphtheria chiefly attacks children of school age, from five to fifteen and it is clearly proved that the disease is influenced by school attendance. Dr. Power has shown conclusively that, by an aggregation of children at school, you can deliberately manufacture a potency of diphtheria. The reasons for this are chiefly the special infection from the breath of those who are congregated together for any length of time, and the limited space set apart for the scholars. There is also the danger, at young ages, of children passing confectionery from mouth to mouth, of drinking from the same unwashed cups, the absence of ventilation, and other conditions."

He laid special stress upon infection through the medium of milk, and advised every one to leave off drinking raw milk. He also named the lower ani-

¹ Pepper, vol. II, p. 941; Hand-book of Medical Sciences, vol. III, p. 65, and vol. VII, p. 790.

mals and especially the domestic cat, as carriers of infection.

Isolation was recommended as absolutely essential. In hospitals there should be much more attention to the amount of *lineal* space per bed, which he deemed of more importance than cubic air-space or high rooms. No child should go to school from a house where there is a sore-throat. The system of keeping up "average attendance" by insisting that all scholars should go to school had done much harm. Everything that touched the mouth or lips of a patient should be burned. Houses should be selected which are not damp, and dense foliage should not grow near them.

THE DISSEMINATION OF SMALL-POX BY TRAMPS.

Special prominence has been given to this subject by the medical officers of health of England, during the past year; and valuable papers have been published by Dr. Armstrong, of Newcastle-on-Tyne, and others. Dr. Armstrong says: "Of 63 towns invaded in 1892-93, the medical officers of health of which have given me the particulars, 37 or 59 per cent., had the infection primarily from vagrants. The disease was brought secondarily by vagrants into 36 towns, including some into which first cases had also been brought by the same class of persons. Such secondary infections occurred as often as nine times in Carlisle, Southampton and Sunderland, twelve times in Warrington, fifteen times in Keighley, eighteen times in Blackburn, and no less than twenty-five times in Nottingham. In nineteen times only out of the 63 towns reporting, was small-pox infection stated to have been brought otherwise than by vagrants; and in seven of these it was subsequently reintroduced by vagrants no less than twenty-five times. As a result of his inquiries Dr. Armstrong presented the following resolutions:

That the Incorporated Society of Medical Officers of Health consider it desirable:

- (1) That vagrants should be restrained in their powers of carrying infection about the country, especially in epidemic times.
- (2) That they should be made to report their movements.
- (3) That they should, when considered requisite, be subject to disinfection and detention for such time as the sanitary authority of the district in which they are may think necessary for the protection of the public health.
- (4) That in epidemic times all persons frequenting casual wards or common lodging-houses should be medically examined on admission.
- (5) That sanitary authorities and the police should have power to detain for medical examination any vagrant found in any public place.

MILK-INFECTION.

Prof. W. T. Sedgwick has contributed valuable papers upon different phases of this subject to the *Boston Medical and Surgical Journal* and to the Twenty-fourth Report of the State Board of Health of Massachusetts. Other investigations confirm the conclusions presented in these papers, first, as to the presence of bacteria in large numbers in milk as drawn from the cow, and, second, as to the question of milk as a medium for the transmission of the infection of typhoid fever.

König,¹ in his recent volume, says: "Cow's milk, although it may leave the udder free from bacteria, will be found to contain them immediately after milking. These bacteria enter the milk by means of hair,

and particles of dirt floating in the air of the stable, and increase with extraordinary rapidity.

Cropf and Escherich² found in milk, two or three hours after milking, by means of Koch's method of cultivation, from 60 to 10,000 colonies, and in five to six hours after milking 200,000 to 6,000,000 colonies per cubic centimetre.

E. von Freudenreich³ demonstrated the rapid development of bacteria in milk as follows; at different temperatures:

	NUMBER OF COLONIES OF BACTERIA PER CUBIC CENTIMETRE.		
	15° C. (60° F.)	25° C. (77° F.)	35° C. (85° F.)
3 hours after milking . . .	10,000	18,000	39,000
6 hours after milking . . .	23,000	172,000	12,000,000
9 hours after milking . . .	46,500	1,000,000	35,280,000
24 hours after milking . . .	5,700,000	577,000,000	56,000,000

Miquel⁴ also testifies to the rapid development of bacteria in milk, and to the fact that the rapidity of development depends upon the temperature of the milk. Although the bacteria may be harmless, their presence must be borne in mind, especially in the use of cows' milk as food for infants. In addition to the harmless bacteria, those which are pathogenic may also gain access to the milk, and thus cause disease.

In Luzerne, Switzerland,⁵ several epidemics of typhoid fever have been traced to buttermilk, which was returned from the creameries to milk-dealers after the cream had been removed for making butter.

A similar typhoid epidemic⁶ is detailed in the Danish "Wochenschrift für Aerzte," which occurred in the fall of 1886 in the three districts of Ore, Haarsley and Skowby, in the island of Fünen. The cause was traced to a common establishment belonging to these three parishes, from which buttermilk was re-sold to customers. Typhoid fever was found to exist at this establishment, and the sick patients had partaken of the returned buttermilk.

Another epidemic traced to buttermilk is reported from two districts in Hanover.⁷

In Groningen, Holland,⁸ another typhoid epidemic was reported in 1886, the cause of which happened to be the infection, in the dairies, of vessels washed with water which had been polluted by the excreta of typhoid fever patients.

Almqvist⁹ reports an epidemic of the same disease which occurred near Göteborg, Sweden, in 1889, in which the cause was determined to be the infection of skim-milk which had been returned from a dairy to the consumers.

Kitasato¹⁰ reports cases of cholera which were caused by the use of infected milk in Calcutta. The investigations of Koch and Kitasato show that cholera bacteria will multiply in milk. Their length of life depends on the reaction of the milk. The sooner it sours the sooner they die.

THE HYGIENE OF OCCUPATIONS.

The well-known observations of Dr. Farr upon the mortality of persons engaged in certain occupations, as deduced from the Registration Reports of England, have been supplemented by valuable papers on the same subject by his successor, Dr. Ogle.

⁶ Ibid., 1890, p. 245.

⁷ Ibid., 1886, p. 875.

⁸ Zeitschrift für Hygiene, 1890, 8, 137.

⁹ Ibid., 1889, 8, 491.

¹ Chemie der Menschlichen Nahrungs und Genussmittel, Third Edition, 1893.

The following is selected from several tables presented by Dr. Ogle at the last session of the International Congress of Hygiene at London.

COMPARATIVE MORTALITY FROM PHTHISIS AND RESPIRATORY DISEASES, OF MEN FROM TWENTY-FIVE TO SIXTY-FIVE YEARS OF AGE, ENGAGED IN VARIOUS DUST-INHALING OCCUPATIONS.

	Phthisis.	Lung Diseases.	Total.
Fishermen (as standard)	55	45	100
Carpenters, joiners	103	85	170
Bakers	107	94	201
Wool-workers	130	104	234
Cotton-workers	137	137	274
Cutlers, scissor-makers	187	196	383
File-makers	219	177	396
Masons, brick-layers	127	102	229
Stone- and slate-quarry men	156	138	294
Pottery-makers	239	336	565
Cornish miners	348	281	579
Coal miners	64	102	166

The point most worthy of note in the foregoing table is the remarkable immunity of coal-miners from phthisis, as compared with the high mortality of the metal miners of Cornwall.

ON THE QUALITY OF THE BERLIN SERVICE-WATER.¹¹

Dr. Proskauer furnishes additional facts upon the effect of filtration of water through sand, as investigated by Piefke and Fränkel.

The volume of water furnished to Berlin is daily on the increase, and this increase is not due alone to the growth of population, but also to a larger consumption per head. Respecting the composition of the unfiltered water of the Spree, and of Lake Tegel, which furnish the city water-supply, the author points out that the experiments carried out during the last few years, with reference to the power of the sand-filters to arrest micro-organisms, have shown that it is imperative that the source of water should be, as far as possible, protected from pollution by human excreta, so as to furnish a raw material of the utmost degree of purity.

In this respect, the water of Lake Tegel is greatly preferable to that of the river as drawn at the Stralau works. The river water is, as a rule, strongly yellow in color, almost always turbid, and has a muddy taste and smell. When allowed to stand, it has at times a considerable deposit, consisting mainly of organic detritus and bacteria. The water of the lake is, as a rule, clear, but occasionally slightly turbid; in color it is pale yellow, and the taste and smell rarely dead and earthy. This, in fact, occurs only when the snow melts in the spring, and there is at certain periods a slight deposit. The bacteriological examinations showed that the river water was usually very rich in germs, and that the number is on the increase. Out of sixty analyses in the period of two-and-a-half years, the number of colonies of bacteria in one cubic centimetre of water was,

In 16 cases or 26.6% of the tests over	100,000
In 23 cases or 38.3% of the tests between 10,000 and 100,000	
In 20 cases or 33.3% of the tests between 1,000 and 10,000	
Only one sample contained less than 1,000 germs.	

Contrasting the totals per cubic centimetre in the present period with those in former years, it appears that in

1884-85 there were from	59 to 8,316 germs
1885-86 there were from	191 to 110,740 germs
1886-87 there were from	750 to 17,000 germs
1887-88 there were from	1,400 to 186,000 germs
1888-89 there were from	230 to 190,000 germs
1889-91 there were from	940 to 360,000 germs

The author believes that the water of the Spree is becoming so polluted that its use must either be shortly discontinued on sanitary grounds, or the filtration must only be permitted to be carried out under the most stringent precautions.

There were only three occasions, however, when the number of germs per cubic centimetre in the water of the Tegel exceeded one thousand.

With reference to the filtered water, the author says the number of bacteria capable of development after filtration were as follows:

During 1889-90 from	12 to 110 per cubic centimetre
During 1890-91 from	9 to 310 per cubic centimetre
During 1891 (last half)	3 to 60 per cubic centimetre

Only three times during the whole period did the number of germs in the filtered Tegel water rise above one hundred per cubic centimetre.

On twenty-three occasions the filtered water of the Spree contained more than 150 germs, the numbers ranging from 310 to 13,000 per cubic centimetre. In certain cases these high ratios of germs were attributed to the freezing over of the filter-beds. The beds at the Tegel works are covered in and cannot become frozen in winter.

After reviewing the chemical and bacteriological analyses of the water, the author points out that only the latter tests furnish an accurate and liable indication of the working of the filter-beds. The quality of the service-water was tested in the mains at various parts of Berlin, and copious tables are given of the analyses of the water, made at stated intervals during the whole period.

LEAD-POISONING FROM A PUBLIC WATER-SUPPLY.

Several cases of poisoning in the town of Calau¹² induced the government to make an inquiry as to the cause. The water was of extreme purity, as indicated by chemical analysis, and contained only five germs per cubic centimetre. It was brought to the town in cast-iron pipes coated with asphalt composition, but the houses were supplied by means of lead-pipes of considerable length. Two months after the water was introduced there, some cases of lead-poisoning were reported among inhabitants where the water remained undisturbed in the pipes during the night. An inquiry conducted under the direction of Dr. Koch revealed the presence of lead, varying in amount from a mere trace to thirteen milligrammes per litre.

The reason for this rapid absorption of the lead was shown to be the richness of the water in free and partially combined carbonic acid, the low percentage of carbonates, and its extreme softness. The tendency to dissolve lead was further increased by the large volume of air contained in the water, which was taken up during its flow through the mains, for at the source it contained no air whatever.

THE WATER-SUPPLY OF PARIS.

The new water-supply of Paris,¹³ now being introduced, will yield a supplementary supply of 25,000,000 gallons per day, at a cost of about \$7,000,000. The sources are two streams, the Breuil and the Vigne, whence it is to be brought to the reservoirs at Montrebon, a distance of about 68 miles, of which 38½ miles are open cutting, 18½ miles are underground conduits,

¹¹ Zeitschrift für Hygiene, vol. xiv, 1893, p. 260.

¹² Ibid., vol. xiv, 1893, p. 296.

¹³ Le Gentle Civil, vol. xxii, 1891, p. 181.

3 miles elevated conduit, and $4\frac{1}{2}$ miles are siphons. The diameter of the open cutting varies from 5 feet 10 inches to 6 feet 2 inches. The reservoirs are designed for a capacity of 10,600,000 cubic feet, and are divided into three compartments.

A NEW DISINFECTING APPARATUS.

This apparatus was designed by Mr. O. Krell and Dr. Rapschefsky, at the direction of the inspector of the medical department of the Russian army. In the first instance all existing forms of apparatus were procured, and were submitted to a searching trial. The conditions laid down for the new apparatus were:

(1) That it should destroy entirely, not only the germs of all known pathogenic organisms, but even those bacilli found to be the most difficult of extermination (the garden-mould bacillus).

(2) That the disinfection should be accomplished in the shortest space of time.

(3) That the apparatus should be as simple as possible, both in construction and in manipulation.

The various systems tested were: (1) hot air; (2) superheated steam; (3) saturated-steam jets; (4) saturated steam at rest, with means for creating high pressure during disinfection; (5) saturated steam at rest at about atmospheric pressure, with means for producing a vacuum by condensation; (6) saturated-steam jets at high pressure, with superheating.

The operations of these various classes of disinfecting apparatus were discussed in detail; and the experiments led to the conclusion that the new apparatus must work by means of saturated steam at a high pressure, with provision for the ventilation of the disinfecting chamber, and with special air-inlets also at the floor level, without special heating apparatus within the chamber, but furnished with heat-accumulators. The apparatus is made of steel, is cylindrical in form (8 feet in diameter and 5 feet long). The cylinder is placed horizontally, and has doors at each end, fastened to bronze rings with six screw-bolts to each. The chamber is tested to a pressure of ten atmospheres at the works, but the safety-valve is weighted to lift at three-quarters atmosphere above normal.

The total weight of the apparatus is about one ton. It is distinguished from all others by its rapidity of working. The previous heating up of the chamber from the cold state takes two minutes; and in fifteen minutes more a temperature of 100°C . (212°F .) is reached, even through a thickness of thirty-two blankets, while, in five minutes more, the temperature rises to 112°C . (234°F .). The disinfection, therefore, even of the most difficult objects, can be completed in twenty-two minutes. The working speed is contrasted by the author with that of other forms of apparatus now in use, and the advantage of saturated steam at 100°C . over heated air, even at 150°C ., as determined by Koch,¹⁴ is insisted upon.

RECENT APPARATUS FOR CREMATION.

Dr. T. Weyl,¹⁵ of Berlin, gives a brief historical account of the practice in all past ages (introduced by the Aryan race), and traces the revival of the practice to the close of the eighteenth century, although from that time till the first cremation in Europe at Milan, January 27, 1876, a period of nearly eighty years

elapsed. Since that date the practice has extended in Italy, till there are now 27 crematories in operation in that country alone.

In Germany, the first crematory was built at Gotha in 1878. No others were introduced till that at Hamburg in 1891, but very soon after others were erected in Heidelberg, Berlin and Offenbach. The number of cremations at Paris reaches a total of 400 annually, and the system is in use to some extent in Switzerland, Denmark, Sweden and the United States. The author classifies the existing establishments under two heads, those without regenerative furnaces and those which adopt this plan. To the former class belong the crematories of Milan, on the system of Gorini, and that of Venini, which is a modification of the former. In the latter class are included the crematory at Gotha, in which, during the period ending November, 1891, no less than 976 bodies had been disposed of. The process here lasts two hours-and-a-half, and the cost is about eighty marks (\$18.50). The system of Bourry at Zurich, the furnace of Toiseul and Fradet at Père-la-Chaise, in Paris, and others at Stockholm and Gothenburg are founded on the regenerative furnace of Siemens. The furnace of Guichard differs from those mentioned by the use of coal-gas and compressed air; it has, therefore, no gas-producer furnace. In an experimental trial of this furnace at Paris, the process lasted forty-six minutes, and involved the use of 190 cubic metres (about 6,700 cubic feet) of gas and 500 cubic metres of compressed air. A table is appended, giving the cost of cremation with each system, together with the time employed in the antecedent heating, and also in the cremation itself.

INFECTIOUS DISEASES.—PERIODS OF INCUBATION, QUARANTINE AND INFECTION, AND SOURCES OF INFECTION.

The following summary is condensed from Dr. L. F. Parkes's recent "Handbook of Infectious Diseases," and will be found very useful to boards of health and sanitary officials for reference, as well as to general practitioners of medicine.

DIPHTHERIA.

Incubation Period: least, unknown; average, 2 days; greatest, 7 days.

Quarantine Period: 7 days from last exposure to infection.

Infective Period: from the beginning of symptoms, for the whole period of illness.

Sources of Infection: 1. From a previous case, acute or convalescent. 2. From a case of apparently simple tonsillitis. 3. From a case of apparently simple nasal ulceration or osena. 4. From domestic animals (cats, pigeons or fowls) suffering from a throat affection of a diphtherial nature. 5. From cows' milk, by human infection of the milk in the cow-sheds and dairies, etc. 6. From fomites, that is, infected bedding, clothes, carpets, curtains, books, toys, cups, spoons, forks, etc. 7. From a person who has been in contact with a diphtheria patient, but who has not himself contracted the disease. 8. From defective sanitary conditions; these are probably merely predisposing causes engendering morbid conditions of the tonsils favorable to the growth of diphtheria contagion when implanted thereon.

SCARLET FEVER.

Incubation Period: less than 24 hours; average, 1 to 3 days; greatest, 7 days.

Quarantine Period: 7 days from last exposure.

Infective Period: from earliest appearance of symptoms, till all desquamation has ceased.

Sources of Infection: 1. From a previous case of scarlet fever, acute or convalescent. 2. From a case of sore throat without discernable rash, but merely a mild form of the disease. 3. From cows' milk, either by human infection of the milk in cow-sheds and dairies, or during the milking, or from a diseased condition of the cows. 4. From fomites. Infection may be carried by persons who are not themselves sufferers, if they have been in contact with patients.

¹⁴ Gesundheits Ingenieur, August 31, 1892, p. 521.

¹⁵ Ibid., 1892, p. 377.

MEASLES.

Incubation period: from exposure to infection to onset of illness: least, 4 days; average, 9 to 10 days; greatest, 14 days.
From exposure to infection to appearance of rash: least, 7 days; average, 14 days; greatest, 18 days.

Quarantine Period: 15 days from last exposure to infection.

Infective Period: from earliest appearance of symptoms till convalescence is well established. The catarrhal stage preceding the eruption is very infectious.

Sources of Infection: 1. From a previous case of measles. 2. From fomites.

MUMPS.

Incubation Period: least, 14 days; average, 21 days; greatest, 25 days.

Quarantine Period: 25 days from last exposure to infection.

Infective Period: from onset of prodromal stage for 2 or 3 weeks subsequent to appearance of parotitis. The chance of infection diminishes progressively from the onset of the disease.

Sources of Infection: 1. From a previous case. 2. From fomites.

GERMAN MEASLES.

Incubation Period: least, 5 days; average, 18 days; greatest, 21 days.

Quarantine Period: 21 days from last exposure to infection.

Infective Period: from onset of prodromal stage to cessation of desquamation.

Sources of Infection: 1. From a previous case. 2. From fomites.

INFLUENZA.

Incubation Period: less than 24 hours; average, 3 to 4 days; greatest, 5 days.

Quarantine Period: 5 days from last exposure to infection.

Infective Period: from earliest onset of symptoms till convalescence is well established.

Sources of Infection: 1. From a previous case of influenza. 2. From fomites.

WHOPING-COUGH.

Incubation Period: least, 7 days; average, not determined; greatest, 21 days.

Quarantine Period: 21 days from last exposure to infection.

Infective Period: the whole period of illness from onset of earliest catarrhal symptoms.

Sources of Infection: 1. From a previous case of whooping-cough. 2. From fomites.

SMALL-POX.

Incubation Period: least, 9 days; average, 12 days; greatest, 15 days.

Quarantine Period: 15 days from last exposure to infection.

Infective Period: from the onset of initial symptoms till all scabs have been removed. The period of greatest infectivity is during the acute stage (vesicular and pustular). During the initial illness and until the appearance of the rash the liability to impart infection is not great.

Sources of Infection: 1. From a previous case of small-pox. 2. From fomites. Infection can be carried by a person who has been in contact with a small-pox patient, but who is not himself a sufferer from the disease. 3. Proximity to a small-pox hospital containing numerous cases in the acute stage.

CHICKEN-POX.

Incubation Period: least, 13 days; average, 14 days; greatest, 19 days.

Quarantine Period: 19 days from last exposure to infection.

Infective Period: from appearance of eruption till this has completely disappeared.

Sources of Infection: 1. From a previous case. 2. Fomites. The infection may be carried by those who have been in contact with the disease.

TYPHOID FEVER.

Incubation Period: least, 8 days; average, 12 to 14 days; greatest, 23 days.

Quarantine Period: 23 days from last exposure to infection.

Infective Period: the excreta are infectious through the whole course of the disease and until convalescence has been established at least a fortnight.

Sources of Infection: 1. Water, food or air contaminated by the specific virus contained in the excretions of a typhoid-fever patient. 2. Fomites. Infection may persist for several weeks in infected clothing and bedding shielded from exposure to light and air.

TYPHUS FEVER.

Incubation Period: average, 7 days.

Quarantine Period: 14 days from last exposure to infection.

Infective Period: from beginning of illness till convalescence.

Source of Infection: From a previous case of the disease.

Fresh air and free ventilation rapidly destroy the virulence of

the contagion. Fomites probably do not propagate the contagion.

ASIATIC CHOLERA.

Incubation Period: least, a few hours; average, 1 to 2 days; greatest, 10 days.

Quarantine Period: 10 days from date of last exposure to infection.

Infective Period: from earliest onset of symptoms till complete recovery.

Sources of Infection: 1. From water, food and air contaminated with the discharge of a person suffering from cholera. 2. From fomites. 3. There is reason to believe that the virus contained in the excreta at the time of leaving the body of a patient and for a short period afterward, is in a less active condition and more easily destroyed by chemical agents than after such excreta have been exposed for a short time to contact with the air.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

J. T. BOWEN, M.D., SECRETARY.

REGULAR Meeting, Monday, January 22, 1894, the President, DR. C. F. FOLSBOM, in the chair.

DR. F. W. GOSS reported

TWO CASES OF PULMONARY CONGESTION AND OEDEMA OCCURRING DURING PREGNANCY.¹

DR. E. REYNOLDS: This subject seems to me one which rests upon a basis of clinical medicine and physiology more than obstetrics. I came to-night prepared to learn rather than to contribute anything valuable to the discussion, and my impression that that would be the case is strengthened by the paper. All that I can say on the question is derived from a theoretical standpoint. We know that in normal pregnancy the systemic circulation labors under an increased obstacle, that that obstacle is thrown back through the left heart on to the pulmonary circulation and the right heart; there is normally then an increase of tension throughout the whole circulatory system. We know that as pregnancy advances the heart normally enlarges. Authorities are divided as to whether it is by dilatation or hypertrophy; the fact, however, being probably, that it is usually a mixed process, though either factor may predominate. Under these conditions it is easy to see that any slight addition to the obstacle may induce an oedema, especially in the pulmonary circulation to which the whole obstacle is thrown back.

Such a complication occurring, the question of treatment, it seems to me, should be primarily solved by a resort to medical measures, everything to strengthen the heart, everything which can relieve the system of its added load; depletion of the circulatory system so far as that is consistent with the patient's general strength. But the question of the induction of labor seems to me a very difficult one. We know that in normal cases cardiac symptoms develop during labor in a large proportion of all instances, from the fact that during the contractions of the uterus, and during the increased tonic pressure upon the uterine vessels in labor, the extra load which the heart is already carrying is actually increased again, and that many hearts fail to compensate this extreme load even under normal circumstances.

Where the heart has already given out during pregnancy, I should question much the wisdom of adding to it the extra load of labor. I should feel I should

¹ See page 336 of the Journal.

not be willing to recommend the induction of labor until all medical means had been exhausted, and should personally feel that I should be unwilling to do it until after consultation with the best authority in clinical medicine whom I could obtain. If, as in Dr. Goss's second case, the woman recovered sufficiently to be in fair condition, and yet not so thoroughly but that there was a strong prospect of a recurrence of this very dangerous complication, I should be inclined to induce labor, but I should feel that in that case everything was in favor of the most rapid methods, of those which would least prolong the added strain upon the heart, due to the pressure of the contracting uterus. Such cases are, of course, unfit for anæsthesia. In some cases rapid delivery without anæsthesia is impossible because the muscular fibres of the cervix resist dilatation too firmly. In other cases, and especially in those in which the patient is already in a state of exhaustion, a moderately rapid dilatation of the os by the hand can be carried on without anæsthesia, to a degree which at least will permit the introduction of one finger. When one finger can be introduced into the uterus it is usually possible to hook down the foot of the fœtus at six or six and a half months; and by traction on the foot, any os can be gradually dilated, the fœtus acting as a wedge, and exerting pressure from above. I should be inclined to believe that such a method as that would be much preferable to any gradual induction of labor, but as I said, I can speak of this question only upon theoretical grounds and not from experience. My own experience with pulmonary œdema as a complication of pregnancy has been wholly limited to cases of renal origin with which, as I understand it, this discussion is not concerned.

DR. C. M. GREEN: I can add very little to the subject; I came to learn. It has always been taught that in such cases induction of labor should be the last resort; that medical measures should be the first recourse; and only on their failure and in critical condition of things, as a last hope, labor should be induced. I am reminded of a case which I saw in consultation, where the cause of death was uncertain; but the clinical history of the case was very similar to that of Dr. Goss's cases. The patient was taken with serious dyspnoea. There was œdema of the lungs and some lesion of the heart, I believe. She was, however, more nearly advanced to term, and I am not sure she was not very near to term. It was thought best to deliver her, and it was done; but the patient died after a few days of the combined difficulty, which, I believe, was somewhat of the kidney and somewhat of the heart. I should, I think, in such cases place my chief reliance on medical measures, should relieve the lungs by action upon the kidneys and bowels. The literature of the subject is very scanty.

DR. A. L. MASON: I should like to ask, whether in cases of extensive œdema of the lungs from pregnancy, Bright's disease or other causes, there is any objection to the use of pilocarpine subcutaneously.

DR. GOSS: In the first attack of the second case Dr. Clement used pilocarpine subcutaneously, hoping to relieve the condition of the lung, and the patient was relieved by its use. There was a profuse increase of saliva, the woman bending forward and the secretion running from her mouth. I suppose there is always the risk of the patient being drowned, so to speak, by the profuse secretion in the use of pilocarpine under such circumstances. Regarding the induction of pre-

mature labor in the second case, as far as the child was concerned it seemed to me there was not much hesitancy because there was every evidence that the child was dead. I sought counsel before proceeding to induce labor; and in this case, at any rate, relief was obtained, and there has not been recurrence of the serious attacks. Medical treatment had been thoroughly tried, and the patient still remained in a precarious condition, and it seemed to me that the induction of labor was the only thing remaining to be tried. I think the method pursued was safer than rapid dilatation and forced delivery would have been.

DR. GREEN: I have used pilocarpine in pulmonary œdema of renal origin especially, and very rarely has it seemed to do harm. I recall one case of extensive œdema of the lung, in which I thought the patient would drown, so extensive was the salivary secretion. She, however, recovered. It seems to me that with careful watching, to guard against the depressing effects of pilocarpine, and by keeping the heart well supported, it is a safe drug and acts very successfully.

DR. REYNOLDS: I should like to add the same experience with a single exception of one distressing case that I saw in consultation, that did die; but I think the drug relieved the condition in a number of other cases.

DR. MASON: Recently a case of a different nature came under my observation, a man with Bright's disease and very extensive œdema of the lungs. The question of pilocarpine came up. It seemed to me there was so much œdema that it was not a good drug to use, and it was not used. I am glad to know that it is generally safe.

A CASE OF APPENDICITIS.

DR. C. F. FOLSOM: Last night (Sunday) I went to my office at 9.30, and found a lady waiting to see me in reference to a member of her family who had slight pain in the lower part of the abdomen, thought to be due to having eaten a raw apple the previous evening. She had vomited slightly Saturday evening, and had had two loose discharges. She had been moderately comfortable during the day. I said I should rather see her before suggesting anything, but the lady said it was quite superfluous, as there was nothing serious the matter. I called and found a slight localized tenderness inside the crest of the ileum on the right side. The patient looked perfectly well, pulse below 100, had had a slight chill. I said I would see her again in the morning. I found she had had a rather uncomfortable night, and the tenderness had become a little more diffused, extended nearly to the umbilicus, but also in the left side and above the umbilicus and the epigastrium. Temperature 101.5°, pulse 104, no vomiting during the day or night or to-day, and there had been no very great pain. No resistance could be felt, nothing in the way of tumor. It seemed to me it could not be anything else than appendicitis. Dr. Porter saw her and concurred in the diagnosis. The diagnosis having been made we both urged an early operation. The operation was done this afternoon at five o'clock. The striking features in the case in my mind were the very slight symptoms as compared with the gravity of the condition which Dr. Porter found. It was difficult to persuade the patient that she had serious trouble; there were no marked constitutional symptoms and yet the appendix was found to be gangrenous. I should have said that there was no special

tenderness, pain or sense of resistance at the so-called McBurney point at any time.

DR. C. B. PORTER: The case was extremely interesting because it had been induced, as the family thought, by indiscretion in eating an apple. I found, on examination, that there was more resistance to pressure over the region of the appendix, but there was also extreme sensitiveness to the touch on the left side above the umbilicus and just below the ensiform cartilage. Considering the temperature, the localization (especially at Dr. Folsom's first visit) in the right iliac fossa, and not being able to think of anything else it could be, it seemed to me wise to operate. The very extensive sensitiveness seemed to me indicative of a threatened general peritonitis (if it had not already started), with its origin probably in the right iliac fossa. I made an incision for the ordinary operation for removal of the appendix; and when I got down to the junction of the small with the large intestine, it was impossible to find any appendix. Upon turning the ascending colon upwards, I could feel the induration underneath, and upon dragging it all out, it was found that the appendix, which was very long, was drawn back and was all adherent on the posterior surface, but that there was no pus. As soon as I had discovered a band running off to one side, I commenced to dig it out with my finger a little, and then there came a puff of that foul gas, significant of anything gangrenous, and I said, "My finger has touched it if I have not yet seen it." Dissecting further I found I had the base of the appendix laid bare near the junction of the cæcum and ileum, and down further, behind the cæcum, was the rest of it so imbedded that I could not tell what was appendix and what were the surrounding parts. I passed an aneurismal needle underneath the base of the appendix, tied two ligatures and cut between. I then dissected it away, and at about the middle it broke entirely, it was so gangrenous, and left a piece deeply placed that had to be dissected afterwards. As soon as the bowel was cut the lumen at both ends was touched with a 95-per-cent. solution of carbolic acid to prevent infection. Finally, I succeeded in digging out the rest of the appendix. It is interesting to see the extent to which the destruction had gone. I have operated on a few cases as gangrenous as this, and one fully as much so within twenty-four hours, and it goes to show how important it is for cases which are suspected to be appendicitis to be thoroughly studied with reference to immediate operation.

DR. E. B. BRACKETT read a paper on

THE USE OF GYMNASTICS IN THE TREATMENT OF LATERAL CURVATURE.³

DR. E. H. BRADFORD: My views are so thoroughly in accord with Dr. Brackett's that it is hardly possible for me to discuss, as I agree with everything he has said. I think he has hardly laid stress enough on the fact, which I think he was one of the first to call attention to, that is, the necessity in cases of this sort of slight osseous change, of avoiding forward curving of the spine. To express it in more common language, what a patient with a rotary lateral curvature needs to do, if it is desired to correct the deformity, is to attempt to become what is known as a backward athlete, namely, that class of athletes who can bend the spine backward to a greater extent than is nor-

mally possible. Any one who has examined the back of one of this class of athletes will have noticed its peculiar character, namely, not only how symmetrical it is, but also how the physiological curves are diminished; and the exercises and practices which are necessary to produce this are what is needed in treating rotary lateral curvature with any osseous change. This is entirely independent of exercises for the development of muscles. Exercises for the development of muscle, as Dr. Brackett says, are useful and important to enable the patient to maintain a correct attitude; but for corrective exercises attention should not be paid so much to the muscles as to increasing the flexibility of the spine and the contraction of the limb muscles.

DR. E. M. HARTWELL: My belief is that ordinary gymnastics are worth nothing, or next to nothing, in the treatment of scoliosis, except in so far as they may be made serviceable in giving tone and power to the muscles of the back after the spine has been straightened, or its deformed curves reduced by other more appropriate and effective forms of procedure. By ordinary gymnastics, I mean school gymnastics and the various forms of light and heavy gymnastics that are taught or practised in most gymnasia. The ordinary gymnastic teacher or director is apt to be so wedded to mere "muscle-building" as to be a blind adherent to the doctrine that scoliosis is due chiefly to disordered or impaired muscular action. Any one who professes to treat a fully-developed scoliosis by means of customary gymnastic exercises, having only the resources of an ordinary gymnasium at his command — be that gymnasium never so completely equipped with pulley-weights and gymnastic machines — transcends his functions and promises what he cannot perform. Even the so-called medical gymnastics should be looked upon as an adjuvant therapeutic measure chiefly, and not, as so many uncritical enthusiasts would have us believe, as the sole or even the most effectual means of reducing or abolishing a scoliosis. I entirely agree with Dr. Brackett and Dr. Bradford in holding that muscular exercise alone is totally inadequate to the task of straightening a scoliotic spine in which any considerable degree of rigidity has declared itself. That school and recreative gymnastics, if they are well taught and diligently practised during childhood and the first stage of adolescence, are of great value in counteracting the deforming attitudes imposed so often on school children, and so far, both are efficacious in preventing scoliosis, I have not any doubt.

It cannot be gainsaid, I think, that the *Sjuk-gymnastik* of the Swedes includes many mechanical procedures, among those they call passive movements, that are capable of rendering efficient aid in increasing the flexibility of a not wholly rigid spine, so that its deforming curves may be corrected. If once the spine is redressed massage and active exercise of the atonic and atrophic muscles come into play as corroborative measures. When torsion is present, or anatomical changes have been wrought in the vertebræ and the vertebral ligaments, the work of supplying and redressing the spine is tedious and expensive, often extremely so.

The medical profession owes a debt of gratitude to Dr. Gustaf Zander, an acute and accomplished physician of Stockholm, for the patience and mechanical genius displayed by him during the last thirty years

³ See page 329 of the Journal.

in developing the so-called Mechanical Medical Gymnastics. Dr. Zander has invented and brought into use a series of some seventy machines, by means of which the appropriate effects of the more important active and passive movements embraced in the Swedish movement treatment can be secured more effectually, certainly and cheaply, where numbers of patients are concerned, than is possible under the conditions which usually obtain in the practice of medical gymnasts, be they never so skilful.

The Zander machines are divided into two main classes, namely: (1) those that afford active exercise to the patient, being set in motion by him; and (2) those that are actuated by a steam- or gas-motor, against the "passive resistance" of the patient. The first class includes thirteen machines for arm-movements; thirteen for leg-movements, and thirteen for trunk-movements. The second class includes five machines for distinctively passive movements, and thirteen for various, purely mechanical, manipulations. In cases requiring massage, Dr. Zander has recourse to manual massage, being of the opinion that machinery cannot be successfully substituted for the hand, in this branch of mechano-therapy. The construction of both classes of machines is such that the work required of the patient in overcoming resistance can be accurately measured and hence adapted to his strength and needs. In this respect the Zander machines are unequalled.

Dr. Zander has attained marked success in the treatment of scoliosis, through the use of his so-called orthopedic machines. These machines are ten in number and constitute a series quite distinct from those already mentioned. In the construction and use of his orthopedic machines for the purposes of correction and redressing, Dr. Zander employs devices to secure suspension, corrective posture, counter-pressure and counter-rotation in varying degree, according to the nature and state of the scoliosis present. He also has recourse to certain machines belonging to the two classes mentioned above, for the sake of restoring and increasing the action of the muscles concerned in maintaining the normal curves and position of the spine; but mechanical support by means of fixed bandage or corsets do not form a part of his treatment, though it well might, it seems to me.

As an aid to testing and controlling the effects of his treatment he makes frequent minute and searching measurements to determine the relations of the bony prominences of the spine, shoulders, thorax and pelvis to each other. The results of such measurement are plotted in the form of a mathematically constructed chart, and are of great practical value. In making the measurements alluded to Dr. Zander uses two very ingenious, and I must add expensive, measuring machines invented by himself; they are shown in the collection of pictures of the Zander apparatus, which I present for your inspection. One of them enables him to determine the amount of deviation of the spine both in the frontal and the sagittal plane measured in millimetres, and the other shows the contour of the thorax at any level that may be chosen — below the axillæ.*

In general, Dr. Zander's treatment of scoliosis accords in principle with that of Professor Lorenz of Vienna, except that the latter makes use of fixed bandages and of very cleverly constructed wooden-corsets, of which the specimen presented is a sample; while

Zander lays more stress on minute measurements for purposes of control than does Lorenz. Both Lorenz and Zander employ mechanical measures for corrective purposes, and muscular exercises for tonic and retention purposes after reduction has been in some measure secured. Lorenz employs forcible pressure or *redressement forces* in the manner shown on page 178 of Bradford and Lovett's "Orthopædic Surgery." Zander's method of applying forcible pressure and counter-rotation is less violent and more deliberate.

Zander's principal paper on the treatment of scoliosis is entitled, "Om Den Habituela Skolioseris Behandling Medels Mekanisk Gymnastik," and was published in the *Nordiskt Medicinskt Arkiv*, 1889, Band XXI, No. 22. The article, which is well illustrated, is in Swedish, but it is accompanied by an abstract in French. Nebel's "Bewegungskuren mittelst Schwedischer Heilgymnastik und Massage mit besonderer Berücksichtigung der mechanischen Behandlung der Dr. G. Zander, Wiesbaden, 1889, contains the best and fullest account that has yet appeared of Zander's contributions to mechano-therapy.

It is interesting to note that both Lorenz and Zander hold that the principal provoking cause of scoliosis, in those who are most afflicted by it, namely, growing school girls, is found in the faulty positions they are so often obliged to assume and maintain in writing. Indeed, Lorenz declares that "the majority of habitual scolioses are writing-positions become fixed." So far as I am aware there are no comprehensive statistics to show whether or not scoliosis is more frequent in the United States than it has been shown to be in Germany, Sweden and Denmark. It seems to me reasonable to suppose, however, that the proportion of scoliotic girls in our schools is needlessly great; since our vicious systems of teaching writing are frequently rendered doubly dangerous owing to the careless and unscientific way in which so many of our school-children are furnished with chairs and desks.

I have recently had occasion to study the seating of the children in the public schools of Boston. My observations confirm those of Dr. C. L. Scudder, who showed that the assortment of desks and chairs in respect to size, was quite inadequate to the hygienic needs of pupils. I have examined the chairs and desks in one hundred schoolrooms, taken at random and ranging in grade from the high school to the primary school. In only eighteen out of one hundred class-rooms did I fail to find gross misfits. Of the pupils seated in the remaining seventy-two class-rooms, no less than twenty per cent. were misfitted. By misfitted, I mean that either they could not place their feet flat upon the floor, or they had their knees in contact with the under surface of their desks. It seems to me hardly reasonable to expect that sixteen to eighteen minutes of gymnastic exercise daily, which is all that is permitted in our schools, should prove adequate to counteract the deforming tendency of vicious postures in writing and study, especially when so large a proportion of the pupils are forced for more than two hundred minutes a day to maintain exhausting and abnormal positions because of the neglect of the authorities to provide them with suitable desks and chairs.

DR. BRADFORD: One word in regard to the recording of lateral curvature. There is no question but that the Zander recording appliance is the best that exists for the purpose for which it is designed. There is one difficulty which has not been mentioned, and that is

* The construction and working of Dr. Zander's principal orthopedic machines was explained by the aid of pictures and diagrams.

true of all the recording appliances which have been hitherto exhibited, namely, that the record is made with the patient standing. It is absolutely impossible to fix a patient perfectly still while he stands during the marking of the record. Schultze has written upon this question, and he states that while the record is made the patient may alter his position a number of times. Of course, with great care, as no doubt Zander uses, fairly good results may be attained, but there is a very simple way of obviating all this and making records with simpler apparatus, namely, by having the records made while the patient is lying down. This gives a more accurate record of the rotation, and that is the most important record. In regard to the subject of Lorenz treatment with apparatus, I think what Dr. Hartwell has said in regard to the matter shows conclusively that Lorenz is right in claiming that mechanical gymnastics should be supplemented by the use of some appliances during the intervals of gymnastic exercises in all urgent cases.

In regard to the wood corset, it may be said that is one of the best that has been devised. It, however, has one disadvantage in our climate, and that is that it does not bear hot weather so well as some of the other forms; and personally I am inclined to think the paper corset which has been perfected by Dr. Weigel is superior to the wood corset.

DR. GOLDTHWAIT: I have been very much interested in the subject of gymnastics as applied to the treatment of scoliosis, and have watched with a good deal of interest the methods and the results obtained in the hands of pure gymnasts; and while I am a firm believer in gymnastics in these cases, both for muscular development and to increase the flexibility of the spine, at the same time I feel firmly convinced that they represent only a portion of the treatment, and that they must be supplemented by some apparatus. I was very much interested in seeing Dr. Zander's apparatus, and one cannot see it without being very much impressed by the mechanical ingenuity of the man; but at the same time it seemed to me that results equally good could be obtained with apparatus much less complicated and much more at the command of the average practitioner of orthopaedics than is Zander's apparatus, there being only one such institute in this country and that one in New York.

DR. BRACKETT, in answer to a question, said: The discussion has broadened somewhat from what I intended. I agree fully in relation to the lack of weakness in the majority of cases. At the Children's Hospital I have had collected every case that has been treated there for eighteen months, and we fail to find a marked or any appreciable weakness in the majority of these cases. It is true, however, that we find a good many of them coming on in young and growing girls, or after some exhausting disease, or during a period of a great deal of depression, in which very likely we can attribute it to more of a general lack of tone than to actual muscular weakness. On the other hand, we have not found a decided unilateral weakness, that is, we have tried to prove or disprove or to have observations upon the question of unilateral weakness, and so far the figures do not show enough of change to consider it of any value. With reference to the improvement in gymnastics alone, there is one condition I think we often meet with, that is a child who will come for treatment and be given purely a gymnastic treatment as we have tried as a matter of observa-

tion. There is no doubt that for a while there is a decided improvement. I have been led to think that that is due simply to the improved muscular tone, or else to the improved energy and pride of the patients by which they are able to hold themselves more correctly, that is, the effort is continued for so much longer a time that the general condition of the case seems improved. But as to the actual weakness for which the muscular development is claimed by certain people, I have never yet been able to find any basis for it.

Recent Literature.

Dissections Illustrated: A Graphic Hand-book for Students of Human Anatomy. By C. GORDON BRODIE, F.R.C.S. With plates drawn and lithographed by PERCY HIGHLEY. In four parts. London and New York: Whittaker & Co.

The author's plan has been to offer the student a series of pictures of dissections, with a few diagrams and some short descriptions. The plates are reduced one-third from the natural size. We have received the first and second parts, which treat of the upper and lower limb. The illustrations are beautiful. The dissections are of the standard type. There are no sections nor "window-cuts." The areolar tissue and fat have been removed and the parts shown according to time-honored practice. Deep dissections follow more superficial ones, so as to give the student the successive layers. Such being the lines on which the work is undertaken, we have nothing but praise for its execution by both the anatomist and the artist. T. D.

The National Dispensatory. Containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, including those recognized in the Pharmacopœias of the United States, Great Britain and Germany, with numerous References to the French Codex. By ALFRED STILLÉ, M.D., LL.D., Professor Emeritus of the Theory and Practice of Medicine and of Clinical Medicine in the University of Pennsylvania; JOHN M. MAISCH, Ph.M., Phar.D., Late Professor of Materia Medica and Botany in Philadelphia College of Pharmacy, Secretary to the American Pharmaceutical Association; CHARLES CASPARI, JR., Ph.G., Professor of Pharmacy in the Maryland College of Pharmacy, Baltimore, and HENRY C. C. MAISCH, Ph.G., Ph.D. Fifth edition, thoroughly revised, according to the Seventh Decennial Revision of the United States Pharmacopœia. Imperial octavo, 1910 pages, with 320 engravings. Philadelphia: Lea Brothers & Co. 1894.

This encyclopedia of materia medica, therapeutics, pharmacy and the collateral sciences has, through the extraordinary energy of its editors and publishers, appeared only five months after the publication of the last revision of the United States Pharmacopœia, and but a single month after that official work went into legal effect.

As one of the best-known commentaries upon the United States Pharmacopœia, the late thorough revision of that work has necessitated a like revision in this commentary, yet the revision has been by no means restricted to such necessary changes, but the latest editions of the British, French and German pharmacopœias have been exhaustively searched for materials of

value, and ample space has been given to such, and to the new synthetic remedies and to the drugs, which although as yet unofficial in any pharmacopœia are being largely used. The present edition is thus more than one hundred pages larger than the previous one.

The descriptions of *materia medica* are clear, thorough and systematic, as are also the explanations of chemical and pharmaceutical processes and tests. The therapeutical portion has been revised with equal care and the statements of the action and uses have been arranged not only alphabetically under the various drugs, but for practical medical usefulness have also been placed at the instant command of those seeking information in the treatment of special diseases by being arranged under the various diseases in a therapeutical index. The readiness with which any of the vast amodnt of information contained in this work is made available is indicated by the twenty-five thousand references in the two indexes at the end of the volume.

For the physician and the pharmacist, for whose use it was specially prepared, this edition will no doubt prove to be more than ever valuable. B. F. D.

How to Use the Forceps. With an Introductory Account of the Female Pelvis and on the Mechanism of Delivery. By HENRY G. LANDIS, A.M., M.D., Professor of Obstetrics and Diseases of Women and Children in Starling Medical College, Columbus, O. Revised and enlarged by CHARLES H. BUSHONG, M.D., Assistant Gynecologist and Pathologist to Demilt Dispensary, New York. Illustrated. New York: E. B. Treat. 1894.

This book is divided into three parts: Part I, Mechanism of Labor; Part II, the Forceps; Part III, Application and Cases.

Part I is interesting not only as a sample of the way in which a single mind frequently strikes out new truths which meet too tardy acceptance, but also for its intrinsic worth. Although Dr. Landis's views of fifteen years ago are at variance with the accepted teaching of to-day in some minor points, as, for instance, in the importance which he ascribes to the parietal protuberances in the production of rotation, they are, in the main, in thorough accordance with the views now held by most progressive teachers. The exposition of the mechanism of labor contained in this little book is especially clear, and will be of value to every one interested in the subject.

Part II contains a set of excellent directions for the use of the forceps. It is clear, detailed and accurate, though some of the views expressed are perhaps not quite brought up to date. Most obstetricians of to-day would consider that the chapter on "When to Use the Forceps" is a little over-conservative.

The book so far is excellent, and will furnish valuable reading to any one interested in the subject. It is a pity that as much cannot be said for Part III, "Application and Cases," which adds but little to the book, is sketchy, and rather crude.

The printer and publisher have done good work.

Operation Blanks. Prepared by W. W. KEEN, M.D., Professor of the Principles of Surgery in the Jefferson Medical College, Philadelphia, Pa.

By filling up these convenient forms, instructions may be given to the nurse, the family physician and the attendant. The plan of operation blanks is a capital one, but we fancy that the majority of surgeons would prefer to select their own list of dressings.

THE BOSTON Medical and Surgical Journal.

THURSDAY, APRIL 5, 1894.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

ANTI-VACCINISM.

SCARCELY a year has elapsed during the past ten years in which the opponents of compulsory vaccination have not petitioned the Massachusetts Legislature for a repeal of the existing laws. The unusual prevalence of small-pox, and the consequent increased interest in vaccination during the present season, have led to a renewal of the opposition, and at least four hearings have been devoted to the subject by the Legislative Committee on Public Health. At the first hearing two of the petitioners spoke at considerable length. Their statements presented almost the same identical arguments which have been used for nearly a century in opposition to vaccination, and followed very closely after their predecessors, Birch and Rogers, who, as long ago as 1805, attempted to disprove the value of vaccination. The statements were made up chiefly of theory and denunciation, with such reasoning as the following:

"The vacciniest's statistics are worthless, and may be made to prove anything. You will find, if you look into this point of the controversy, that the vacciniest is hopelessly given over to a belief in the efficacy of vaccination, and that he constructs his statements unfairly, and solely with the view to support a preconceived opinion. After the mind has given itself up to this absurdity, all that follows is easy, and passes without scrutiny, without analysis."

As much as to say that the careful statistical investigations of the German Government upon this question (the most thoroughly vaccinated people in the world), together with those of the Local Government Board of England and those of the Hungarian statistician, Körösi, are all false and worthless.

One of these gentlemen made the remarkable statement that "vaccination increases small-pox." Dr. Alfred Russell Wallace attempted to prove the same proposition before the present Parliamentary Commission of England, but when asked by the Commission

to examine his figures more closely was compelled to retract his statements, and honestly admitted the worthlessness of his figures.

At the second hearing ten or a dozen persons presented testimony, prominent among whom was a member of the Boston School Committee (not, however, appearing as a representative of any action or sentiment of the Committee), who stated a considerable number of alleged injuries and deaths from vaccination, in not one of which was any evidence given that the alleged harmful results were anything more than a coincidence such as might occur in a very large number of vaccinations, and not necessarily a consequence of the operation.

Considerable stress was laid upon the death of Dr. W. Stokes, which occurred at the City Hospital in 1889, but which has been repeatedly shown to have had no connection with a previous vaccination in the relation of cause and effect.

At the third hearing, Ex-Attorney-General Pillsbury made a very brief argument for the petitioners, his principal point being that vaccination as a preventive against small-pox should not be compulsory, so long as similar preventive measures are not compulsory in the case of tuberculosis, rabies and other diseases.

A half-hour was then given to the remonstrants who supported the existing laws. Senator Buckley, of Holyoke, in a very convincing five-minute address, told the Committee of the practical necessity of vaccination in the paper-making, rag-consuming city of Holyoke, and of the defenceless position in which that city would be left without the protection afforded by the present statutes.

The fourth hearing was entirely devoted to listening to Mr. Pickering, an anti-vaccination missionary from London, who has spent considerable time during the past winter in Rhode Island, Indiana and Massachusetts as a vigorous opponent of vaccination. Much of his argument had little reference to the subject, consisting, as it did, of certain arrogant claims of ability to cure cases of small-pox in marvellously short periods of time by methods of his own. He appeared to be quite incensed at the city authorities, who would not allow him free admission to the Small-Pox Hospital of Boston.

It is quite remarkable that nearly all opponents of vaccination, not excepting those who have appeared at our State-House this year, in quoting foreign statistics, and especially those which relate to Germany, are wont to pass over in silence the period which has supervened since the Franco-Prussian War. As a matter of fact, the German compulsory law did not take effect till 1874, since which time small-pox has almost entirely disappeared from Germany, while the partially vaccinated neighboring countries have suffered severely from this cause.

On the day following the last hearing the Legislative Committee reported, "leave to withdraw."

As a comment upon this hearing before the Com-

mittee on Public Health of the Massachusetts Legislature, it is legitimate to quote the following from a very recent editorial in the *New York Times*:

"H. Hitchcock, M.D., writes to us from the executive office of the Anti-Vaccination League to ask a candid question, to which we will give a candid answer. 'Are you willing,' he asks, 'to open your columns to a discussion of the question of vaccination?' We reply: 'No,' for it would not be worth the doctor's while, nor ours. There is at the present day no question of vaccination except in the minds of the members of anti-vaccination leagues—gentlemen and ladies who are engaged with perfect sincerity, we have no doubt, in a futile attempt to head off human progress and to reopen a question about which pretty much all the world has made up its mind. The appeal of the American Anti-Vaccination League is, in our judgment, an appeal to ignorance and prejudice."

THE UNFAVORABLE SEQUELÆ OF CERTAIN RADICAL OPERATIONS ON THE GALL-BLADDER.

THE accidents and evils of biliary lithiasis are among the most general of all hepatic affections, being common to all nations and all climates. To rid the afflicted of these evils, three radical surgical operations have of late years been devised: cholecystotomy, cholecystectomy and cholecystenterostomy.

Cholecystotomy, first performed by J. L. Petit in 1748, in cases where the gall-bladder, distended by calculi, was attached by firm adhesions to the abdominal wall, afterwards (1859) proposed by Thudicum as worthy of wide extension, did not definitely obtain a place in modern surgery for the otherwise irremediable accidents of biliary lithiasis till the operation was successfully performed and advocated by Marion Sims in 1878. It is the simplest and safest of all the radical operations, is indicated in all cases of chronic lithiasis, attended with frequent attacks of hepatic colic and other troubles, where, on careful examination, there is found to be complete patency of the choledochus duct.

In this operation, an external fistula is established, by which there is an escape of bile, and the principal danger is that this fistula shall become permanent. This danger is emphasized by the author of a recent voluminous work on the liver, Labadie-Lagrave; such permanent fistulæ have occurred in the practice of Walker, Robeson, Terrillon, Tait and others, though infrequently, and Seymour, as the result of his personal experience, regards the danger as very slight, believing "that it is only when an obstruction in the common duct has been unrelieved that this can occur."¹ It cannot be said that "ideal cholecystotomy," in which the gall-bladder is opened and the calculi removed, then the organ is carefully sutured with catgut and restored to the abdominal cavity—it cannot be said that this procedure is to be recommended if, according to Langenbuch, it be attended with a very serious danger. The ductus choledochus, he says,

¹ Medical Record, December 6, 1890.

reacts to any excitation in a remarkable manner; this is the reason why this canal becomes swollen after the excitation caused by an operation, the tumefaction preventing the free flow of bile; there is a regurgitation of it, and the bladder fills up; finally the sutures give way and the bile is thrown into the peritoneal cavity, and the patient dies. Lawson Tait also, in a recent discussion on the surgery of the liver, regards "ideal cholecystotomy" and cholecystectomy "as based on fallacious reasoning and dangerous methods."² With regard to cholecystectomy, the principal reason why this operation should not be chosen in preference to cholecystotomy, *when the latter is feasible*, has been given above; and it seems agreed that the usefulness of cholecystectomy is limited to cases where the tissues of the gall-bladder are diseased and where this organ cannot be sutured to the abdominal walls.

Cholecystenterostomy is an operation of still more recent device, being first performed by Winiwarter in 1881, though Nussbaum, a year earlier, had conceived of the operation and advised it in the following words: "When the escape of bile through the natural duct is no longer possible, it will be practicable to make an artificial connection between the gall-bladder and intestine through which the gall can again escape into the intestinal tract." This operation, according to Murphy's statistics,³ had been performed by the old method of sutures twenty-three times up to December, 1893, with a mortality of thirty-five per cent., or eight deaths in twenty-three cases. Of the seventeen cases where the operation had been performed with Murphy's anastomosis button (from June 11, 1892 to December 1, 1893), there was in every instance a good recovery.

This record, of course, speaks favorably for the anastomosis button; but what the public would like to know more particularly is the after-history of the successful cases. Were these persons restored to a good degree of working vigor, or did serious infirmities follow? In one of Mayo Robson's cases, the gall-bladder was stitched to the colon; what was the effect on this patient of the constant diversion of the biliary secretion from the small intestine into which it is normally poured during a certain stage of the digestive process?

We have, fortunately, a full statement of results from a well-known member of the profession, who has lately gone through the operation for relief of jaundice by retention due to irremediable stenosis of the choledochus — we refer to the recent report of Dr. Dujardin-Beaumetz to the French Academy, March 13, 1894.

The patient, whose gall-bladder has been made to open into the intestine, is constantly menaced with biliary infection. In the physiological state, although the choledochus opens into the duodenum where microbes exist in abundance, yet owing to the peculiarities of its anatomical conformation, microbes rarely penetrate the duct; when there is a biliary fistula with a free communication between the gall-bladder and

intestine, the liability to microbic penetration and infection of the liver is much greater. This infection manifests itself by febrile accessions of a remittent or intermittent type.

There is also more or less intestinal dyspepsia, resulting from the fact that the biliary fistula opens into the intestine at a variable distance from the ampulla of Vater, and there is now want of concordance between the pancreatic and biliary secretions. Gastric dyspepsia, more or less intense, is certain to follow; this is likely to take the form of acid dyspepsia (hyperchlorhydria).

For the hepatic infections and the febrile symptoms resulting, Beaumetz advises intestinal antiseptics by salol and the administration of quinine in lavements. When there is acid dyspepsia, fifteen grains of bicarbonate of soda may be given one hour before meals. The diet should be mainly vegetable. It must, however, be borne in mind that the subject of this kind of biliary fistula will never be in a really normal condition again, either in respect to digestion or nutrition, but "they will be enabled to live, and in conditions relatively favorable, thus deriving incontestable advantages from surgical intervention."

MEDICAL NOTES.

SMALL-POX IN CHICAGO. — The number of cases of small-pox reported to the Board of Health of Chicago for the month of March was as large as that for both January and February combined.

ATTEMPT TO BURN A HOSPITAL. — The third attempt within a short time to burn the Topeka City Hospital occurred recently, but the fire was discovered in early season and no serious damage was done.

A VICTIM OF PROFESSIONAL ENTHUSIASM. — Dr. Adolf Meyer, assistant in the Schonborn's clinic at Wurzburg, died recently from diphtheria contracted in doing tracheotomy. The tube became obstructed by membrane; and to save the patient from asphyxiation Dr. Meyer put his mouth to the canula and cleared it by aspiration. He died a few days later.

SOAP AND WATER IN GLASGOW. — In a lecture at the London Institute, on "The Chemistry of Cleanliness," Prof Vivian Lewes said, when speaking of the wasteful action of hard water on soap: "The introduction of the new Loch Katrine water-supply to Glasgow has saved the city several thousand dollars a year in soap; and, mind you, Glasgow is not a place where they waste soap."

INCREASE IN SUICIDES IN NEW YORK CITY. — The mortality reports of the New York Board of Health show that while the total mortality of the city has risen since 1883 from 34,011 to 44,370 per year, the number of suicides has increased from 161 to 313. In the last ten years, while the general mortality has increased about one-fourth, the mortality from suicide has increased nearly one-half.

² Edinburgh Medical Journal, October, 1893.

³ Medical Record, January 13, 1894.

TYPHOID FEVER EPIDEMIC AT MONTCLAIR, N. J. — An outbreak of typhoid has occurred at Montclair, N. J., some thirty families having one or more patients each. Nearly all the cases are said to have occurred among the customers of a single milkman, in whose family two cases of typhoid fever are known to exist. The Board of Health has forbidden the sale of milk from this source.

LIQUOR RIOTS IN SOUTH CAROLINA. — The working of the new State Dispensary Law in South Carolina is not satisfactory to the people of that State, or at least to a certain proportion of them; and last week several riots occurred in various parts of the State between the people and the State police. At Florence a mob broke into the State Dispensary and destroyed the entire stock of liquors.

FIVE MALE GENERATIONS. — The five female generations recently reported in this column have their counterpart in a family in an English village where, according to the *Medical Press*, there are now living the following members of one family: T. D., aged ninety-seven; G. D., his son, seventy-three; G. D., Jr., grandson, forty-eight; J. D., great-grandson, twenty-six; and G. D., great-great-grandson, six years old.

SUICIDE IN THE GERMAN ARMY. — The number of suicides in the German army is 6.33 in every 10,000 men; while in the French army it is but 3.33, and in the English 2.09. Saxony and Silesia furnish the largest number of suicides. According to the published statistics, the causes lie, aside from the natural suicidal tendency of the German race, in the fear of punishment and the wretched treatment the private soldier has to endure.

DEATH OF COMMANDER CAMERON. — Commander Verney Lovett Cameron, who was sent out to Africa by the Royal Geographic Society in search of Dr. Livingstone, was killed last week by a fall from his horse while hunting in Bedfordshire, England. He was the first European to cross the entire breadth of the African continent, in its central latitudes, beyond the western shore of Lake Tanganjika, to the Atlantic sea-coast of lower Guinea, making the greater part of the journey on foot.

AN INCIDENT OF THE CHOLERA AT JEDDA. — An astounding instance of the unconcern which was shown towards the loss of life by cholera during the pilgrimage in the East last summer has come to light in the sentence by an English court of the captain of a vessel conveying pilgrims home from Mecca and Jedda. In a storm many were washed overboard and others died of disease, nearly two hundred in all perishing. The captain made no mention of this in his log, for which omission he was fined twenty-five dollars.

DAMAGES FOR INVALIDISM FROM SHOCK. — The Supreme Court of Minnesota has ruled, that where the evidence tends to show that prior to sustaining a personal injury a woman was healthy and active, but by such injury is rendered a helpless invalid, an award of

\$10,000 damages is not so large as to warrant a reviewing court in saying that they are excessive. In the case on trial the injury for which damages were awarded was in itself slight, but medical testimony supported the plaintiff's claim that the nervous shock resulted in cardiac and neurotic disease.

THE INTERNATIONAL MEDICAL CONGRESS. — Harold Frederic, in his London letter in the *New York Times* of April 1st, says of the International Medical Congress in Rome: "Italy may be wallowing in the mire of poverty, but she manages none the less to give the International Medical Congress the finest reception it has yet had in Europe. Not much money has been spent; but the King and Queen, Crispi, and the Court have been prodigal of personal attention and interest, which had a much greater effect than mere financial lavishness. Visiting doctors, both English and American, write me in terms of almost excited enthusiasm over their experiences in Rome, where they are treated as the guests of the whole city." As the Congress met on March 29th, Mr. Frederic's correspondents must have written very promptly on going home from their pleasant reception.

THE MICHIGAN STATE BOARD OF HEALTH AND TUBERCULOSIS. — The Michigan State Board of Health, in adopting its rule that hereafter all cases of consumption or other diseases due to the bacillus tuberculosis shall be reported by householders and physicians, has acted in a most rational manner in calling attention at the same time to the fact that isolation of the patient is not looked for or expected. The sole purpose of the new law is to secure to the various boards of health information of the locality occupied by each person affected with tubercular disease, with the view of giving him trustworthy information as to how he may avoid re-infecting himself and infecting others, and telling persons most endangered how to avoid contracting the disease. In a similar manner, the New York State Board compels the registration of all tuberculous persons, but does not attempt sanitary visitation and disinfection except under certain conditions. The Philadelphia Board does not require registration, but simply attempts an active educational campaign in the matter of preventing the disease.

THE PRACTICE OF MEDICINE IN MAINE. — A correspondent sends us the following clipping from the Rockland (Me.) *Courier Gazette*, concerning the social and financial status of the physician in one of the small island towns: "There is talk of getting up a time to raise money to help keep our doctor here another year. He cannot stay on what practice he gets, and we cannot afford to have him go. The most of us know what it is to go to the main and Carver's Harbor for doctors. Let's wake up and get up a good time and raise what money we can for the good cause!"

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — During the week ending at noon, April 4, 1894, there

were reported to the Board of Health of Boston, the following numbers of cases of acute infectious disease: diphtheria 38, scarlet fever 58, measles 4, typhoid fever 2, small-pox 6 and 3 deaths (all in unvaccinated persons). There are now twelve cases at the small-pox hospital on Canterbury Street, and three cases at Gallop's Island. No cases were reported to the State Board of Health from places elsewhere in the State.

BEQUEST TO THE LYNN HOSPITAL.—The Lynn Hospital and the Home for Aged Women have each received a bequest of one thousand dollars, by the will of the late Edward H. Johnson, of Lynn.

THE POPULATION OF BOSTON AND ITS VALUE.—According to the *Census Bulletin on Finances of Municipalities*, just issued at Washington, the population of Boston is 448,477, and the assessed valuation of real and personal property in the city is \$822,041,800, which is an assessed valuation of \$1,832 *per capita*, not including the Public Library twins, who possess no personal property.

NEW YORK.

THE ACADEMY COMMITTEE AND THE BILL FOR A NATIONAL BUREAU OF HEALTH.—On March 28th a delegation of the New York Academy of Medicine, among whom were Drs. William H. Thomson, George F. Shrady and Richard H. Derby, went to Washington and argued before the House Interstate Commerce Committee in favor of the Academy's bill to establish a National Bureau of Public Health. Dr. T. Gaillard Thomas, the chairman of the committee of the Academy having the matter in charge, was not able to leave New York, and a paper prepared by him was read by Dr. Derby.

TUBERCULAR MENINGITIS FROM MILK.—An apparently well authenticated case of tubercular meningitis, the direct result of drinking milk from a tuberculous cow, is reported from Yonkers. The patient, the four-year-old son of Mr. William A. Harper, of the publishing house of Harper & Brothers, who married a granddaughter of the late Rev. Henry Ward Beecher, gave no sign of ill health until the 1st of March, when the family physician was called in. The symptoms presented were those of tubercular meningitis, and later the diagnosis of this disease was confirmed by Dr. M. A. Starr, Professor of Diseases of the Nervous System in the College of Physicians and Surgeons of New York, who was called in consultation. The child died March 27th. The milk used by the family was supplied by two fine Alderney cows which were purchased about a year ago, and which had always seemed to be perfectly healthy. After the child's death, however, the Koch lymph test was applied by Veterinary Surgeon J. B. Lamkin, and the presence of tuberculosis was indicated in both animals by the rise of temperature following the injection. A careful examination also revealed evidences of tuberculosis in the udder of one of them; and it is claimed by Dr. Brush and other authorities that the milk of a tuberculous animal cannot convey the disease unless the mammary gland

is affected. It is stated that several weeks ago Dr. Lamkin reported to the Board of Health that he had found tuberculosis among the cattle of Yonkers.

Miscellany.

PERFORATION OF THE HEART, WITH CONTINUANCE OF LIFE FOR THIRTEEN HOURS.

AN unusual case of prolonged existence with a perforated heart is reported by Dr. Thompson, of San Bernardino, Cal.¹ The man was a Mexican, twenty-nine years old, five feet seven inches in height, weighing one hundred and sixty pounds. After the shooting he complained of internal pain over the abdomen and of great thirst. He was given morphia subcutaneously for the pain and shock, and was carried by wagon and train to San Bernardino, a distance of some length. He died a few moments after reaching the hospital, *thirteen hours* after being wounded.

The autopsy, four hours later, showed "a bullet-hole two and-a-half inches inside and one-third of an inch below the centre of the nipple line; size of wound at point of entrance, five-sixteenths of an inch, almost round. The bullet penetrated the cartilage of the sixth rib, near its juncture with the rib, breaking it, and chipping a small piece out of the upper part of the seventh rib. Entering the pleural cavity, the course of the ball was downwards and slightly inwards; this cavity was filled with blood. Passing through right side of the pericardium, penetrating the right ventricle of heart, one-and-a-half inches from apex, it passed through the anterior wall, severing the right coronary artery. Leaving the heart, the ball passed directly downward, penetrating the diaphragm, entering and passing through the left lobe of the liver from above downward, entering the small intestines. The ball having perforated the wall of the intestines, followed them through their action, and was found about two inches up the rectum."

HYPNOTIC SUGGESTION IN THE CURE OF ASTHMA.

THE astonishing effect of hypnotism in the relief of symptoms is well illustrated by a case of asthma reported by Creed.¹

The patient had received very little benefit from treatment of any kind, even "Himrods' Asthma Cure, which was resorted to by the late Earl of Beaconsfield during his last illness," failing to more than mitigate the paroxysms. He was hypnotized daily for ten days, and appropriate suggestions made. On the third he was much relieved, and slept on only one pillow; while on the tenth he was free from respiratory distress, and could walk with considerable speed.

Nevertheless, the cure was not perfected, as he has occasional modified attacks of dyspnoea so that he is now provided with a written order "to sleep when he reads it and to awake after five minutes, breathing freely." This he always carries, and says that it never fails him. There are numerous polypi in both nostrils, which have not been removed for fear of making the cure by hypnotism questionable.

Correspondence.

PROPOSED REDUCTION OF THE ARMY MEDICAL CORPS.

AN ATTEMPTED LEGISLATIVE OUTRAGE.

MR. EDITOR:—It is with indignation that all lovers of justice will look upon the latest endeavor of certain members of Congress to injure the efficiency of the Medical Corps of the United States Army by reducing its numbers 35 men.

This measure, now pending, is a buncombe attempt to gain credit for economy with political constituents; and the medical men are selected for attack because they, and more is the pity, do not combine politically for self-defence, and are therefore a safe mark. In this case the bill is a most insulting one to these honorable physicians, implying as it plainly does that 35 of their number draw pay without earning it.

It is well that the facts of the case should be clearly formulated. The Army Medical Corps consists of 193 members, attending to various hospital routine work, drilling the hospital corps detachment in field and other duties, and ministering to the medical and surgical needs of the 28,000 soldiers, constituting the present United States Army; and also attending their wives and families; a total of soldiers and adult male civilians at United States Army posts being to-day 43,431.

These 193 doctors are scattered over an area greater than all Europe, and divided among the 120 military posts.

In event of field duty at any time, it is plain that one surgeon, at least, must accompany the troops, from each post, and another should stay behind to take medical supervision of the hospital and of the women and children. It will thus be seen how small—even too small—is the present corps. Moreover, it occasionally happens that a doctor (being human) falls ill; and thereby reduces the effective list. Several are thus incapacitated at this time. And again, the law permits officers to take a month's vacation in each year without loss of pay. Therefore this reduces by one-twelfth the list actively on duty, and about 16 medical officers are thereby relieved for a time. As a matter of fact, such is the pressure of duty that the Surgeon-General must often refuse this well-earned vacation, compelling continual duty.

A simple calculation will suffice to show that these various factors, and the present five vacancies, reduce the number of the active medical corps much below its nominal strength of 193 members; and should the present bill removing 35 more become a law, a grievous injury will be inflicted, not only on the efficiency of the corps, but also on the soldiers and their families, who must look to the United States Medical Corps for attendance in sickness.

If it be alleged that contract surgeons—civilians—might be appointed to fill these vacancies at a lower cost, the reply is obvious; that there is now no appropriation made for contract doctors, though formerly this was the case; and even if there were, there is no provision of law whereby they can be placed in charge of the medical department at a military post. Therefore they cannot take charge of the discipline and field drill of the hospital corps detachment, nor be responsible for the post hospital with its supplies. To effect economy as far as practicable, the Surgeon-General has long employed only private physicians at all the arsenal posts in the country; these being small ones. A further grinding down of medical estimates is worthy of the hearts and intellects from which the thought emanates.

Should this bill pass, it will, of course, stop the operation of the new Army Medical School which is doing such good work and which employs itself with the special education in sanitation of hospitals and troops, commissary knowledge, bacteriology, military surgery and other subjects urgently needed by the new men among the assistant surgeons.

No further comment is needed save the statement that

upon March 15th, the Commanding General of the United States Army, Gen. J. M. Schofield, addressed a letter to the Secretary of War stating that this bill would be "seriously injurious to the Military Service," also "the Medical Corps of the Army is none too large for the necessities of the Service." And yet it is considered likely that this measure will pass the House! MEDICUS.

METEOROLOGICAL RECORD.

For the week ending March 24, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Deaths reported 2,642; under five years of age 1,015; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fever) 393; diphtheria and croup 145, measles 47, scarlet fever 47, diarrhoeal

diseases 46, whooping-cough 32, typhoid fever 32, small-pox 15, cerebro-spinal meningitis 15, erysipelas 10, malarial fever 4.

From diarrhoeal diseases New York 20, Fall River 7, Philadelphia 6, Brooklyn and Nashville 4 each, Washington and Cincinnati 2 each, Boston 1. From whooping-cough New York 8, Brooklyn 7, Philadelphia 5, Washington 4, Fall River 2, Boston, Cincinnati, Nashville, Charleston, Cambridge and Gloucester 1 each. From typhoid fever Cincinnati 7, New York 6, Philadelphia 5, Cleveland 4, Milwaukee and Charleston 2 each, Boston, Washington, Fall River and Lowell 1 each. From small-pox New York 7, Brooklyn 4, Boston 3, Lynn 1. From cerebro-spinal meningitis New York 5, Cleveland 3, Milwaukee 2, Boston, Worcester and Lynn 1 each. From erysipelas Boston 4, Brooklyn 3, New York 2, Somerville 1.

In the thirty-three greater towns of England and Wales with an estimated population of 10,458,442, for the week ending March 10th, the death-rate was 19.9. Deaths reported 3,983; acute diseases of the respiratory organs (London) 434, whooping-cough 145, measles 111, diphtheria 82, scarlet fever 52, fever 39, diarrhoea 30, small-pox (Bradford 4, West Ham 3, Birmingham 2, Bristol, Oldham and Leeds 1 each) 12.

The death-rates ranged from 11.1 in Huddersfield to 25.1 in Liverpool; Birmingham 17.4, Bradford 18.9, Bristol 20.9, Croydon 17.2, Hull 16.9, Leeds 17.2, Leicester 19.3, London 20.4, Manchester 21.7, Newcastle-on-Tyne 19.6, Nottingham 14.9, Oldham 18.8, Portsmouth 14.6, Salford 22.0, Sheffield 19.1, West Ham 20.1, Wolverhampton 23.9.

In the thirty-three greater towns of England and Wales with an estimated population of 10,458,442, for the week ending March 17th, the death-rate was 19.2. Deaths reported 3,855; acute diseases of the respiratory organs (London) 373, measles 124, whooping-cough 118, diphtheria 71, scarlet fever 47, fever 39, diarrhoea 34, small-pox (Birmingham 8, London 3, West Ham 2, Cardiff and Oldham 1 each) 15.

The death-rates ranged from 12.1 in Croydon to 25.6 in Liverpool; Birmingham 19.3, Bradford 18.6, Bristol 20.5, Leeds 18.2, Leicester 16.8, London 19.3, Manchester 21.1, Newcastle-on-Tyne 12.1, Nottingham 16.3, Sheffield 18.2.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 24, 1894, TO MARCH 30, 1894.

By direction of the President, LIEUT.-COL. SAMUEL M. HORTON, deputy surgeon-general, will report in person to the President of the Army Retiring Board at San Francisco, Cal., for examination by the board.

CAPTAIN WILLIAM R. HALL, assistant surgeon, is relieved from duty as attending surgeon and examiner of recruits at San Francisco, Cal., to take effect upon the completion of his examination for promotion and will then report in person to the commanding officer, Whipple Barracks, Arizona Territory, for duty at that post.

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—A regular meeting of the Society will be held at the Medical Library, No. 19 Boylston Place, on Monday, April 9, 1894, at 8 o'clock, P. M. Drs. M. H. Richardson and G. L. Walton: "The Operative Treatment of Spasmodic Wry-Neck." Discussion opened by Drs. C. B. Porter and J. J. Putnam.

Under oral communications Dr. W. L. Burrage will report "A Case of Tuberculosis of the Female Bladder, Diagnosed and Treated by Howard Kelly's New Method of Direct Inspection and Catheterization of Ureters through Large Endoscopes."

JOHN T. BOWEN, M.D., Secretary.

SUFFOLK DISTRICT MEDICAL SOCIETY.—The annual meeting will be held at 19 Boylston Place, on Saturday, April 28, 1894, at 8 P. M.

Papers.—Dr. F. S. Watson, "Some of the Clinical Features and the Surgical Treatment of Primary Tuberculosis of the Urinary Organs." Discussion by Dr. P. Thorndike and others. Dr. F. H. Williams, "Diphtheria." Dr. W. A. Morrison, "The Value of the Stomach-Tube in Feeding after Intubation"—based upon twenty-eight cases. Discussion by Dr. F. B. Harrington, Dr. Gannett, Dr. C. M. Whitney and Dr. Prescott.

Business.—Report of the treasurer and the librarian. Election of officers. Appointment of delegates to the American Medical Association.

Supper after the meeting.

A. L. MASON, M.D., President.

JAMES J. MINOT, M.D., Secretary.

PHILADELPHIA PATHOLOGICAL SOCIETY.—The semi-annual conversational meeting of the Philadelphia Pathological Society will be held in the upper hall of the College of Physicians Building, Thirtieth and Locust Streets, on Thursday, April 26th, at 8 P. M.

Dr. Simon Flexner, Associate in Pathology in the Johns Hopkins Medical School, will deliver an address entitled "An

Experimental Study of the Nature and Action of Certain So-called Toxalbumins." Members of the medical profession are cordially invited to be present.

AUGUSTUS A. ECHNER, Secretary.

THE CARTWRIGHT LECTURES.

The Cartwright Lectures of the Alumni Association of the College of Physicians and Surgeons for 1894, will be delivered at the New York Academy of Medicine, No. 17 West 43d Street, on Wednesday evenings, April 4th, 11th and 18th, at 8 o'clock, by Prof. Russell H. Chittenden, Ph.D., of Yale University.

Subject: "Digestive Proteolysis." I. General Nature of Proteolytic Enzymes; General Nature of Proteids. II. Proteolysis by Pepsin—Hydrochloric Acid—with a Consideration of the General Nature of Proteoses and Peptones. III. Proteolysis by Trypsin; Absorption of the Main Products of Proteolysis. Physicians are cordially invited to be present.

FRANCIS P. KINNICUTT, M.D.,

WALTER B. JAMES, M.D.,

D. BRYSON DELAVAN, M.D.,

} Committee.

MUTTER LECTURESHIP OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

The next course of ten lectures under the bequest of the late Prof. Thomas Dent Mutter, M.D., LL.D., "on some point or points connected with Surgical Pathology" will be delivered in the winter of 1896-97, before the College of Physicians of Philadelphia. Compensation \$600. The appointment is open to the profession at large. Applications, stating subjects of proposed lectures, must be made before July 1, 1894, to

WILLIAM HUNT, M.D.,

Chairman, Committee on the Mutter Museum,
8 E. cor. 13th and Locust Sts., Philadelphia, Pa.

HARVARD MEDICAL SCHOOL.

EVENING LECTURES.

The next lecture will be given on Wednesday evening, April 11th, at 8 o'clock, by Dr. F. C. Knapp. Subject, "Traumatic Nervous Affections." Physicians are cordially invited.

RECENT DEATH.

EDWARD BROWN-SEQUARD, M.D., died in Paris, April 24, aged seventy-six years. He was born in the island of Mauritius, but received his medical education in Paris, graduating in 1840, at which time he had already acquired considerable reputation as an experimental physiologist. He received five prizes from the French Academy, and twice received the queen's grant for the encouragement of science from the British Royal Society. He engaged in the practice of medicine in Mauritius until 1864, when he travelled extensively in England and in this country, lecturing and giving private medical instruction. In London he did much work as the head of the Hospital for the Paralyzed and Epileptic. In 1864 he was made Professor of the Physiology and Pathology of the Nervous System in the Harvard Medical School, a position which he held for four years. In 1869 he returned to France, where he was appointed professor in the School of Medicine at Paris, and in 1873 came back to the United States and began practice in New York, and with Dr. Seguin commenced the publication of the "Archives of Scientific and Practical Medicine." After a short residence in London he returned to Paris where he has since resided. In 1878 he succeeded Claude Bernard as professor of experimental medicine at the College of France. In 1881 he was awarded the Baly Medal by the Royal College of Physicians of London. He was for several years president of the French Academy of Sciences. He wrote much and was a most enthusiastic investigator in questions of physiological medicine. Among his published volumes are "Lectures on the Physiology and Pathology of the Nervous System," "Paralysis of the Lower Extremities," "Lecture on the Nervous Affections." He established in Paris the *Journal de la Physiologie de l'Homme et des Animaux*. A few years before his death he discovered the true elixir of life which should rejuvenate and prolong human existence.

BOOKS AND PAMPHLETS RECEIVED.

Retinitis Albuminuria. By L. Webster Fox, M.D. Reprint. 1894.

Original Articles.

THE CHARLES RIVER IN ITS RELATION TO THE ETIOLOGY OF INTERMITTENT FEVER.¹

BY R. W. GREENLEAF, M.D., BOSTON.

THE etiology of intermittent fever is so little understood to-day, that, excepting that a micro-organism has been discovered in the blood of patients suffering with the disease, we know but little more about it than did our predecessors of fifty years ago. Indeed, as evidenced by certain articles in our journals and discussions in our medical societies, it would appear that we do not know as much.

With our present knowledge of micro-organisms it is a little singular that this corner of medical literature should still be clothed with the phraseology of the past, oftentimes containing a partial truth, but so imperfectly expressed as to be misleading and inadequate for practical purposes.

Not a few writers are still urging, in otherwise excellent papers, hypotheses as diverse from each other as inconsistent with observed facts.

Among supposed causative agents we still hear of "atmospheric conditions," "marsh miasma," "river mists," "sewage contaminations," etc.; also that intermittent fever is an "exotic of tender growth," a "stranger in this part of the country," and the like. It would be of the greatest interest if some one could present a perfectly demonstrated theory of the whole course of events, from the taking of the causative agent from its habitat outside the body to its mode of entrance into the body, and through the various stages of its history in the body. The difficulties in the way of so complete a demonstration are so great that I am encouraged to present the following views as to this question, which, though not wholly proven, will serve to co-ordinate distinct data and to give us a "working hypothesis," sufficiently complete for practical purposes. They were derived from a study of the conditions found during a house-to-house inquiry along the banks of the Charles River in the vicinity of Boston, and from a comparison of the data thus ascertained with the reports of observers elsewhere.

In common with other regions in and about Boston, intermittent fever has not been present in the area under consideration for a long time, until within the past six or eight years. A common impression prevails that the Charles River is in some way responsible for its introduction. For instance, even in the utterances of the profession, we hear of the disease "creeping up the valley of the Charles." The offensive conditions due to the refuse of various factories, starch, grease, etc., also the sewage contaminations and the exposure of mud flats have all been held responsible as at least having furnished a nidus for a causative agent "introduced from elsewhere." There is no question that each of these unsanitary conditions has existed, though some of them have since been removed. My studies have led me to conclude that there is equally no question that none of these conditions are causative agents, *per se*; moreover, that we need not look elsewhere to find the offending cause. In other words, that it is right here at home, has been here all along, and is likely to show itself (as it has of late with us), just as it does elsewhere, whenever we establish the

conditions of its existence and introduction to our bodies.

Before presenting these views in detail, permit me to call to your attention what appears to be a fully demonstrated law applicable to, and most useful in the study of the causes of epidemics; namely, that when a cause is general in nature, such as the contamination of a water-supply, as in the case of the cholera epidemic in Hamburg, that the distribution of the cases, when plotted on a map, is widespread, and shows what may be called a markedly characteristic "curve." This is most graphically shown in the data furnished by Professor Sedgwick in the last Report of the State Board of Health, which marks an era in the American study of epidemiology. I will pass about the maps showing the distribution of typhoid fever in Lowell and Lawrence. In these cases the cause was fully demonstrated. Furthermore, since the measures suggested by the Board were adopted in the city where their advice was fully taken, typhoid fever has practically become non-existent. On the other hand, locally acting causes give rise to cases which when plotted are seen to present an equally characteristic "curve." Professor Sedgwick has also demonstrated this in connection with epidemics in which the milk-supply was shown to be the probable agent in the spread of the disease. (See same Report.)

To apply this law to the conditions under consideration, Townsend's exhaustive analysis of the 106 cases in Boston in 1892 shows that two areas were particularly affected, namely, the South Cove and the West End near Poplar and Brighton Streets. He did not explain their distribution. He simply considered that many of them were imported, as from the Newtons; but the points applicable to our inquiry are that he does not report any cases immediately along the river's bank, moreover, that his cases were for the most part grouped around local centres. In the discussion following Dr. Townsend's paper, Dr. John Homans, 2d, referred to a few cases occurring on Marlborough Street, subsequent to the digging up of the street. These, with a single exception on Beacon Street, are the only cases I heard of as having originated near the water front. Further negative evidence as to the river being a causative agent for Boston's cases is that the park police, who pass a considerable part of their time along the Charles-bank have had no cases of the disease among their number. That this is not a question of their lack of susceptibility is evidenced by the fact that several of them were ill with it during the war.

Careful inquiry for some distance along the banks failed to find a single case; though in places unsanitary conditions were found, yet intermittent fever was unknown. Several families had lived in the same places for many years, even twenty and thirty, and had been free from malarial disease. The first locality I found affected was at Barry's Corner. Here in a damp neglected settlement, six cases had occurred within the past three years. An interesting fact was, that still nearer the river, on the same marsh, was a more cleanly and drier settlement. In this place those of whom I inquired knew of no cases.

No other cases of importance were found on this side of the river until reaching Watertown. Here in an extremely unsanitary area, including two sub-areas near at hand, about a dozen cases were found. It is noteworthy that in this area seven of Watertown's nine cases of diphtheria and one case of her seven cases of

¹ Read before a meeting of the Cambridge Society for Medical Improvement, February 26, 1894.

scarlet fever had occurred since the first of the year. Further along the river were cases close by a pond whose level had recently been much lowered. Still further along, in a particularly dry and apparently healthy place, the only case near at hand was in the person of a gentleman whose occupation called him daily to a particularly damp part of Newton. As you are aware (and the details will doubtless be presented this evening), there have been a great many more cases in the Newtons away from the river's banks than in its immediate neighborhood. Some occur near ponds and some occur on hillsides, but their relative infrequency near the banks of the river certainly tends to show that the river, *per se*, is not a causative agent.

The last cases to which I would especially call your attention on the south side of the river, occurred among workmen engaged in digging up around a brook (the Cheese-Cake Brook) in connection with sewer improvements. Five or six men were affected during the summer of 1892, when the soil was first dug up.

Following down the north bank, a very similar outbreak occurred among workmen engaged in "improving" a large estate in Waltham near the Watertown line. It is to be noted in passing that they were digging up what was practically a primeval soil, that is, undisturbed, damp, forest soil.

Along this north bank long stretches were found with no, or only a few cases. In the mills and at the arsenal about one in fifty persons had had the disease, but they were found to live in some especially malarious centre elsewhere.

Passing down to Cambridge, a very interesting relation was found, similar to that referred to on the south bank, namely, a far less number of cases near the river than at a distance from it. You will recall the valuable paper of Dr. Stevens on "Malaria in Cambridge and Vicinity," published in the *Boston Medical and Surgical Journal*, December 29, 1892. He showed the prevalence of the disease in North Cambridge near the clay-pits and near Fresh Pond. In some places so many men were ill as to seriously cripple the working forces. You will observe, however, that he has nothing to say of cases near the river. Moreover, inquiry of other physicians assured me that very few of Cambridge's cases had occurred there. My personal inquiry for the most part verified their statements. Foul odors and other unsanitary conditions, even *in extremis*, had existed in places along the banks but intermittent fever was relatively rare. About the only cases I found were in a settlement just to the west of the Cambridge Hospital. Here, in a little valley formed by the sloping banks of a small water-course, were several. At this place, besides the attendant dampness, the most unsanitary conditions existed, for example, one of the houses, a double one, had an un-walled privy in an old shed, just behind the rear and on the shady side of the house; on this side also were the kitchens; and on the easterly side was an old cess-pool. In this house both families were sufferers, and intermittent fever had also attacked the persons who had lived there the year before. The other cases had occurred further along the settlement. The only other case I heard of in this neighborhood was in the household of the landlord of these houses. This case may have arisen from the Fresh Pond centre, and skipped over the intermediate households; but certainly its origin is far better explained as in some way due to the infection among the tenants.

It would thus appear, first, that all the cases of intermittent fever on the immediate banks of the Charles River are localized about special foci. This shows most clearly when they are plotted as on this map, and, according to the law expressed above, excludes any cause that is general in its action, as would be the river *per se*, or any of its especially unsanitary conditions; and, secondly, that in each centre there was present some local condition of especial dampness, as by recent disturbance of the soil, as a possible associate of a causative factor.

Let us next consider what light is shed upon the subject of the origin of these cases by studying the data furnished by others.

Intermittent fever is a very widespread disease. It occurs in one form or another in various tropical countries. It ascends through the temperate regions of both hemispheres, reaching into Canada in our hemisphere, and into the countries bordering on the North Sea in the eastern. One of the best accounts on this part of the subject is that of Boudin in "*Géographie et Statistique Médicale*," published in Paris in two volumes in 1857. Though notably a disease of swampy lands, as around the Isthmus of Panama, and the Pontine Marshes about Rome, yet mountainous regions are not exempt. But wherever found, the cases are localized about special foci. Another fact stands out prominently in all accounts, namely, that some condition of dampness is invariably mentioned. Either an old mill-pond has been dried up, or a river has overflowed its banks and subsequently exposed an expanse of damp soil, or a mass of forest vegetation has recently been dug up, or a sewer or other excavation has been made. No matter what the views of the author may have been, whether he upholds the "ground-water" theory, the "clay subsoil," "atmospheric agencies," or whether he has taken pains to tabulate the temperature, rains, winds, etc., one is almost sure of finding mention of some condition of dampness.

Other facts in the distribution of intermittent fever are closely correlated with the above. One of these is that certain localities, even if surrounded by water, if their soil is well drained, that is, is not marshy, are notably free from the disease; for example, in many oceanic islands it is practically unknown. A similar fact is that sailors and marines have a much smaller percentage of cases than is found among troops stationed on shore. Data of this sort show that dampness, *per se*, is not the cause of intermittent fever, but is only an associate of the cause; in other words, it appears to be only such dampness as occurs on land in association with organic matter, whether the dampness itself is due to rainfall, or to pond or river overflow. Moreover, portions of countries if particularly dry, as the Cape of Good Hope, or if with abundant river drainage but without much marshy land, are notably exempt from malarial diseases. Still another fact showing the close relation of the disease with dampness is, that where it has prevailed and the soil later has been well drained the disease has disappeared. This has been abundantly shown in the experience of Brooklyn, N. Y., in Washington, and in places in other countries, as in the various parts of England.

In this connection I would call your attention to the fact that in a new country, as in our West, intermittent fever is very common; indeed, in Wisconsin, as I am informed by a physician whom I intend to quote at length presently, this has so forced itself upon

the notice of settlers that they are unwilling to occupy dwellings constructed over cellars recently excavated through the *débris* of vegetable growth, whether such growth is in swampy land or on a mountain side. Their experience has taught them that to do so would most likely result in malarial illness in their household. They wait till all is dry before occupying their houses.

In the long respite from malarial diseases which is now being broken in upon hereabouts, I fear we are losing sight of certain facts which have a most important bearing on the subject. We forget that when our ancestors settled here they found conditions practically the same as we are now finding in the West, and that they found intermittent fever here. This is clearly shown in the Boylston Prize Essay of our venerable and honored poet-teacher, Dr. Oliver Wendell Holmes, written in 1838, nearly sixty years ago, but standing to-day as one of the best expositions of the etiology of intermittent fever for practical purposes extant.

We forget that all through our State, as shown in the admirable reports of the Drs. Adams of Pittsfield and Framingham, Dr. Cook of Natick, Dr. Chase of Brookline, and others, that malarial diseases have been found in several places much longer ago than for the past six or eight years. Indeed, a comparison of the various papers shows that at no portion of the century has there been a time when some towns in New England have not furnished cases, which if the disease had an etiology anything like that of small-pox or scarlet fever, or to that of the supposed mysterious stranger, a "*materies morbi*" which is said to be "creeping up our river courses" in some extraordinary way to-day, all of us would probably have been stricken with the disease by this time.

We forget that the present renaissance of New England activity, with its construction of metropolitan sewers, its building of many suburban homes for merchants of our large cities, and the many problems incident to gas-pipe, drain-pipe and electric-railway construction has practically arisen hereabouts within the past six or eight years, and that previous to that time Boston and Salem and Plymouth and Cambridge, as regards building operations and the like, were practically in the condition that certain of our suburbs, as Chelsea and Charlestown, are in to-day. Indeed to-day intermittent fever is heard of chiefly in their newer parts or those recently disturbed in connection with local improvements, as digging up streets and the like.

The next point in our search for a causative agent must be studied with the patients themselves. Not to prolong this paper unduly, let me at once call your attention to the researches of Drs. Osler and Thayer of Johns Hopkins, and of Professor Councilman formerly there also, but now with us; let me refer to Professor Binz of Bonn, and to Dr. Dock of Texas, and to the repeated confirmatory observations of the microscopists of our home hospitals in the last year or two. They have demonstrated beyond a shadow of doubt that in the blood of an intermittent fever patient is a micro-organism which attacks the red corpuscles and is a causative factor of the disease. This is known as a hæmatozoon. At one stage of its life-history it closely resembles an amoeba, and passes through a variety of stages (crescentic, granular, etc.), and then appears outside the corpuscle as a flagellated form. This is not a bacterium. Its affinities are with the monads, the lowest of organisms in the ascending scale of animal life. The action of cinchona alkaloids in destroy-

ing its life is known, but how it gets into the body and where it lives when outside, are still matters of conjecture. Certain formidable, if not insurmountable, difficulties are in the way of settling these points. One of them is that as far as known no animal can be successfully inoculated with the disease from human blood. The other difficulty is equally formidable. When one learns that there are many micro-organisms in the ground, one is apt to conclude that it would prove an easy matter to solve the problem: I at first so concluded on finding in earth taken from the surroundings of the instructive series of cases I am about to call your attention to, amoeboid forms, granular bodies, flagellate organisms, etc., looking very similar to those found in blood. For a moment I was greatly rejoiced, thinking I could soon solve the difficulty, but on consulting the authorities I learned that all previous inoculation experiments had failed because the soil in all places is apt to be teeming with the bacillus of tetanus, which soon kills the animals experimented upon. At this point of the argument one is forced to say that demonstration wholly fails. I do not see how these points can be fully demonstrated.

When evidence such as has been advanced up to this point in the inquiry fails, it is proper, for the purposes of a "working hypothesis," to rely on what the lawyers call "circumstantial evidence." It would appear that such evidence justifies us in assuming that the hæmatozoon has for its habitat outside the body some form of animal or vegetable life such as is found in swampy land or in decaying vegetation, as on a forest-clad hillside. It is known that such micro-organisms live in organic tissues, both living and dead, and it is not necessary for practical purposes to say just what particular organism the hæmatozoon lives in.

Our complete argument would then stand in this way:

(1) Intermittent fever is a disease always originating locally, thus excluding as etiological factors all causes of a general character.

(2) Intermittent fever is always found to have associated with its origin some conditions of local dampness.

(3) A micro-organism, namely, the hæmatozoon, has been demonstrated as occurring as a causative factor in the blood of patients ill with intermittent fever.

(4) These organisms belong to a group of animals, many of whom are known to live in damp soil, or in animals and plants living in damp soil, thus rendering it extremely probable, especially if we consider our first and second propositions, that the "hæmatozoon" has a similar habitat.

(5) Such micro-organisms may readily be taken into the system in either of the following ways: (a) By drinking water contaminated with moisture from such damp, decaying soil. (b) By entering on food which is contaminated from unclean hands. It seems to me quite probable that, in view of the uncleanly habits of laborers who sit down to their dinner-pails without a thought of washing their soil-stained hands, we may quite sufficiently account for what appeared to be the case in my inquiry, namely, that, relatively speaking, far more cases occurred among hearty laborers than among other classes of people. Professor Sedgwick refers to this method of self-inoculation under the name of "secondary infection," as accounting for a considerable number of cases of typhoid. (c) By cur-

rents of air blowing within limited areas from soil rich in the supposed germs. In view of the widespread opinion that air from malarious marshes is liable to cause the disease, also in view of the cases to which I shall soon call your attention, and of other cases which have come to my notice, this latter seems a probable way also.

You will observe that the first, second, third and a portion of the fourth propositions in the argument may fairly be considered as fully demonstrable and practically already demonstrated; you will also note that the supposition in the fourth, also the fifth proposition, while not to be considered in that category, are in a class of circumstantial evidence of the strongest kind, namely, being wholly in agreement with similar classes of data which have been demonstrated in other lines of argument.

It is an axiom of science that if an hypothesis is sufficiently strong to permit prediction which subsequent data confirms, and that if observations are sufficiently numerous to guard against the probability of individual mistakes, that such an hypothesis explaining a sequence of phenomena, even if incapable of demonstration at every point, ceases to be an hypothesis, but takes the rank of a theory. Indeed, it may become a law; such is the law of gravitation which at first was the Newtonian hypothesis. Such is the theory of evolution, which is an outgrowth with modifications of the Darwinian hypothesis. The view presented in this paper can scarcely yet be called a law, perhaps not even a theory. I would summarize the present state of our knowledge regarding the etiology of intermittent fever as in the stage of strong hypothesis, almost a theory; at all events, quite sufficient for practical purposes, and what naturalists would call a "working hypothesis."

In support of the view that the hæmatozoon lives in a damp soil outside the body, and whether in a swamp or on a mountain side, let me offer the following cases. They nearly complete the chain of evidence.

I did not see any of them personally, but state them as reported to me by the physician in charge of the institution where they occurred. This institution consists of several buildings standing on hilly land, much of which, just prior to their construction, was covered with forest growth. The cellar of one of the buildings was excavated through boggy soil containing much decaying vegetable material, though situated near the top of the hill. Intermittent fever broke out among its inmates soon after it was occupied. Two of the dormitories are situated on the highest hill, and form sides of a quadrangle. The one occupied by the boys was built on land which had been cleared for many years, and was well dried. In this scarcely any cases occurred. The other, the girls' dormitory, was built under exactly similar conditions as to date, plan, etc., except that it was on damp forest-land, a considerable amount of the *débris* of which was disturbed in excavating for the cellar. In this five or six cases occurred daily, until nearly all the girls were ill. The epidemic ceased on digging a trench around the side of the building towards the woods, so that no moisture from them could enter the cellar. These cases may be considered as examples of air-transmission. Another interesting series, illustrating the probable origin from a cause associated with damp soil and decaying vegetable material, occurred in this same institution, in an old stone house situated near the foot of the above-men-

tioned hills. At the very foot, some hundred yards or more from the house, was a swamp. No cases had occurred in this house for many years, nor have occurred within the past year, thus disproving any connection with the swamp. But, just as with the other series, numerous cases occurred in this house when local conditions of a similar character were at hand. In this series, the local conditions were the digging up of soil rich in decaying vegetable matter necessitated in the construction of a roadway and a sewer next to the house.

In judging of the etiology of these cases, it is to be noted that the institution is situated remotely, more than a mile, from the Charles River, and that, although cases were to be found in neighboring towns, yet none were particularly near at hand.

Had such a combination of presumably causative factors, as were found here, existed in the West, such cases would probably not have been allowed to occur. Measures, such as delay in occupancy, and others to ensure dryness of immediate surroundings, would have been taken. In this case the physician in charge feared intermittent fever, but he was overpersuaded, having been informed that, though the disease had been "creeping up our river valleys in the past few years," that it was almost unknown in that immediate neighborhood, and never occurred on hill-tops. He permitted the immediate occupancy of the buildings, and the results proved it to have been a sad mistake. Such cases ought not to occur again in this locality. A due attention to the steps of the hypothesis advanced this evening, though it be not proven at every point, certainly promises us a safeguard. With the present activity in park and metropolitan improvements, and with the growing tendency to building suburban residences, it is well to bear so promising a safeguard in mind. It may prove that the present epidemic may subside at once, as it is already beginning to in several of the places already attacked. Such local subsidence is to be expected in accordance with this hypothesis. It is certainly the wise and prudent course to assume that we have no more immunity from attacks of intermittent fever than is the case with the rest of the world, and that to guard against it we, too, must take the best measures that experience teaches are protective.

TWENTY-SIX CASES OF INTUBATION OF THE LARYNX.

BY FRANK L. DAY, M.D., PROVIDENCE, R. I.

UP to the first of January, 1894, since October 10, 1890, I have seen (each time in consultation with one or more physicians) 31 cases of laryngeal obstruction. These do not include four cases where the child had died previous to my arrival, once each with Drs. Godding, Carpenter, Moore and McKenna, nor one case with Dr. Acres, where operation was refused.

Of the 31 cases seen, in five operation was not advised; of these, three recovered and two died, as follows:

One child, age six, with Dr. Hanaford, of Apponaug, recovered.

Two with Dr. G. E. Carpenter, in East Providence, recovered.

One case seen with Dr. H. P. Abbott was instructive. Male, age five-and-a-half years. A septic case where there had been laryngeal symptoms for twelve

hours. Seen by Dr. Abbott but a few hours before my visit. As the dyspnoea was but moderate, we decided to try steam-inhalation and other medical means for a while. Everything went on well, until twelve hours later the parents took him away from the steam and saw him choke to death without notifying Dr. Abbott, as had been agreed if anything went wrong. The lesson is this: Environment is an important factor in estimating the advisability of operation; and in another case where competent nursing and care was not available, I should operate, even where the dyspnoea was very moderate.

One case seen with Dr. S. A. Welch. A child of two years had been sick but a few hours, a septic case with only moderate obstruction. We decided first to initiate medical means, and saw marked improvement for some hours. The child died of sepsis within twenty-four hours.

In twenty-six cases operation was advised, and these are reported in the table which accompanies this paper.

This series is far too small to be, by itself, of any statistical value, but can only go to help make up, with the reports of others, the great mass of statistics.

Nearly every case served to open up suggestions or to enforce well-recognized points, and some of them I have appended to this report.

Case 1. Here the child's strength had been nearly exhausted by vomiting from repeated doses of ipecac, persisted in the entire night previous to Dr. Munro's first visit, by advice of the former attendant, an uneducated man. It is not the inexperienced only, who even to-day, when called to a case of diphtheritic croup, administer an emetic, as often as otherwise to satisfy the family. There may be cases where a single emetic dose may be useful in helping the expulsion of membrane; but to persist in the use of emetics, or to give them in a routine way, seems to me unjustifiable and inexcusable. I believe the heart-failure in this case is attributable to the weakness induced by emesis.

Case 2. This is the only case where the dyspnoea was not relieved, at least temporarily, by the tube. At first a three-to-four-year tube was inserted, quickly removed, and a five-to-seven-year tube at once introduced. Neither gave relief, and tracheotomy was at once done, partially relieving the breathing for a time. This case serves to emphasize what has been repeatedly said, that the tracheotomy instruments should always be at hand.

Case 4. No urine was voided here for twenty-four hours preceding entrance, nor was any treatment efficient to re-establish renal activity after entering the hospital.

Case 13 also had suppression of urine, coming on two days after the tube had been removed, and when the child was doing well in every way. The family attendant exhausted every means to establish the function of the kidneys without avail.

Case 6 was a very interesting one. The child was desperately ill, and only recovered after a long stay in the hospital. While wearing the tube, it seemed daily, for several days, that he would die, and on one of these days several consultants advised that the tube be removed, lest it be found obstructed. The character of the respiration, which was very rapid, though shallow, and the sound, inclined me to the belief that the tube was clear, and that any extra manipulation would weigh against recovery. The look of a child

struggling for air, usually a slower and labored respiration, is far different.

Case 8. Here the tube became plugged on the tenth day. There was cyanosis and labored breathing. Prompt removal of the tube showed its lumen to be nearly occluded by membrane, and was followed by relief. It was not required afterwards.

In Case 16, could I have foreseen the great dysphagia which was to follow intubation, I should have done tracheotomy at the start. It was the only one where there was so great difficulty in swallowing as to cause me to remove the tube for the purpose of feeding—this after it had been in but eight-and-a-half hours. For two days he did well without it, having only moderate dyspnoea; then I was summoned in the middle of the night, and found him struggling desperately for breath. I had no assistance at the time, and the surroundings for immediate tracheotomy were unfavorable, so the intubation tube was reinserted without any assistance, medical or lay. I decided to leave the thread attached for a few minutes, to facilitate removal if necessary. In a fit of coughing the patient pulled it out, and with it came much membrane. This case well illustrates the danger of leaving the thread attached. Fortunately, the tube had so reamed out the trachea that the obstruction was removed. Had anything been required later, I was prepared to do tracheotomy, owing to the O'Dwyer tube interfering with the taking of nourishment.

Cases 17 and 21 were moribund at the time of operation. They were cases where tracheotomy would never have been considered. It seemed doubtful if the latter would survive intubation even. The whole operation did not require fifteen seconds. The child rallied well, and lived a day and a half. These two cases seem to me to justify the claim of intubation to a definite place in surgery not occupied by tracheotomy.

In Case 18 the tube was coughed up, and did not require to be replaced for twenty-four hours. This child finally died from sepsis. In Case 20 the tube was likewise coughed up after sixty-six hours, but was not needed afterwards. The child recovered.

Case 19 was an unusual one. The whole family had been having influenza, and three weeks previous to operation she had an attack. Her symptoms were anorexia, weakness, insomnia, much gastric irritability and fever, with a general eruption of petechiæ, maculæ, papulæ and blotches. The eruption disappeared, but she did not regain strength. I saw her first November 11, 1892. She had been croupy the day before, but in the evening there was less dyspnoea. Same thing repeated next day. My visit was in the evening, and, as she was breathing pretty well, Dr. Munro and I agreed that it was best not to operate. The following day there was more dyspnoea, increasing towards night, when there was marked cyanosis and retraction. No membrane nor glands. Vomiting constantly. Pulse 145, intermittent. Intubation gave entire relief to dyspnoea, and she soon fell asleep, having had little or no sleep for two or three days. Nourishment taken pretty well. She did well for six hours. We gave a hopeful prognosis. The following morning Dr. Munro was called, and found she had just died, having for the five hours previous grown progressively weaker, and having breathed more and more rapidly, the parents stated. No necropsy was obtained; but it seems probable

that death was from pulmonary oedema, following a catarrhal laryngitis attending influenza.

This series of cases has been especially interesting to me, in carefully watching the way in which the children took nourishment. It cannot be too frequently repeated, that once the tube is in place (whether by tracheotomy or intubation) and obstruction overcome, a case of laryngeal diphtheria resolves itself into the systemic disease diphtheria in the vast majority of cases, and now nourishment is the key to the situation, and the nurse holds that key. Everything else, even stimulation, is subsidiary only. I have been surprised to find in how large a proportion of cases the patient, if in a favorable posture (usually lying on the back or side, with feet elevated a little) can swallow with very little difficulty if fed rather slowly. Here everything depends on the tact and patience of the nurse.

In 25 cases of intubation noted, there was

No dysphagia in	10
But little dysphagia in	13
Much at first, none later in	1
Impossible to swallow in	1

So, in 23 out of 25 cases, these children could take nourishment without great difficulty from the first. This leads me to believe that the difficulty in feeding has been overestimated by most writers. However, much care and patience is often requisite on the part of the attendant.

The tube, then, merely overcomes one of the incidental symptoms, if you please. The disease itself must be fought with food and stimulants, the latter in very large quantity often. The only drugs necessary, from our present knowledge, seem to be mercury and iron. Peroxide of hydrogen is useful locally in the throat.

While in most of the cases the introduction of the tube has been easy, there have been enough trying ones to enforce what is well known, that in young children and in densely infiltrated throats it may be attended with much difficulty.

Case 9 was especially difficult; the fauces were greatly swollen, particularly on the left side, making the glottis seem to be far out of the median line. Here the tube was coughed up after two or three hours, and was found plugged with a single piece of membrane, which showed the bifurcation of the trachea.

Almost without exception, after operation the child coughed a few minutes, then fell into a quiet sleep. The relief of dyspnoea was complete in 22 cases, nearly complete in 2 cases, incomplete in 1 case, and none in 1 case.

By consulting the table, the size of the tube used will be seen in many cases to have been larger than that indicated by the O'Dwyer gauge for a child of that age. The development of the child is more important than the age. I always use as large a tube as can be placed with ease, and leave it in as short a time as is consistent with unobstructed breathing.

As far as I know, there has been no permanent impairment of speech. The average time of wearing the tube in the eight cases which recovered was about five and a half days. The percentage of recoveries was 30.8, but this is of little import. To illustrate the fallacy of statistics in a limited number of cases, the first 20 cases show 40 per cent. of recoveries. Again, the last 6 all died. These were all in the country (in East Providence and Rehoboth), and in a locality

where the type of cases I have seen has been especially septic and malignant, these being a small part of all the cases of diphtheria I have been asked to see (the others not laryngeal) there during the past few months.

The cause of death has been

Sepsis in	7 cases
Extension to bronchi in	5 cases
Uremia in	2 cases
Sepsis and extension in	1 case
Sudden heart failure in	1 case
Oedema of lungs in	1 case
Extension and exhaustion in	1 case

Especially true is it that the type of the disease prevailing at the time determines the death-rate after either intubation or tracheotomy. This is apparent especially from the greatly varying percentages reported by operators in Europe, where intubation has been steadily growing in favor during the past three years.

By no means do I believe that tracheotomy is to be driven into disuse by intubation, in relieving the obstructive symptoms of diphtheria. It is a severer way of accomplishing what, in a large proportion of cases, intubation does; but I would never intubate without having the tracheotomy instruments ready for an emergency, as their use may be imperative in any case.

Intubation involves less shock, requires no anæsthetic, requires no cutting, and is therefore often consented to by parents who would not allow tracheotomy. In very young children it holds out some hope, where tracheotomy is almost always fatal. Being a less severe measure, it may be resorted to earlier, as well as later, than tracheotomy would be justifiable. There is no wound to heal after the tube is removed.

FOUR UNUSUAL CASES: I

- I. IMPERFORATE HYMEN WITH HÆMATOCOLPOS.
- II. MUCOUS CYSTS OF THE VAGINA.
- III. RECTO-VULVAR FISTULA.
- IV. SALIVATION OF PREGNANCY.

BY CHARLES M. GREEN, M.D., BOSTON.

I.

THROUGH the kindness of Dr. C. W. Swan I saw this case April 20, 1893. The patient was fourteen years and five months of age, was well developed, well nourished, and in excellent general health: she attended school regularly, took long walks, was fond of dancing and of the out-door sports of healthy young girls. Neither she nor her watchful mother had seen any symptom of the menstrual molimina; but for three months there had been a noticeable enlargement of the abdomen. For a week there had been a frequent desire to pass the urine; but there had been no disturbance of defecation, no bearing down, no pelvic distress, in fact no discomfort whatever. Advice was sought, however, on account of the gradually increasing tumor in the lower abdomen and the non-appearance of the menstrual flow. Dr. Swan found an abdominal tumor, reaching nearly to the umbilicus, but narrow, and not extending into the iliac regions: the hymen he found to be imperforate.

When I saw the case, I was unable to determine positively whether we had to deal with a distended

¹ Read before the Boston Society for Medical Observation, February 5, 1894.

vagina simply, or whether the uterus and possibly the Fallopian tubes were involved; but the absence of distressing symptoms and the probability that the girl had passed but a few months beyond the age of puberty led me to believe that probably the retained menstrual blood was limited to the vagina. The hymen was found to be bulging convexly outward: this I punctured with a small trocar, and a dark-brown fluid escaped. The discharge was not of tarry consistency, as usually described in the books, owing, I presume, to the fact that it had not been retained sufficiently long for the blood serum to be absorbed to any great extent. After the abdominal tumor had somewhat subsided, I enlarged the opening in the hymen by multiple incisions and thus thoroughly evacuated the vagina. After washing out the vagina with a weak carbolic solution I explored with an aseptic finger: the uterus was found of normal size and the os non-patulous; the tubes could not be felt: it was clear, therefore, that the case was one of hæmatocolpos simply. The vagina was enormously distended and seemed to fill the whole pelvis.

The evacuated fluid was carefully collected and was found to measure three and one-half pints. Assuming that there had been no marked absorption of the serous constituent, and accepting the common statement that the normal average amount of each menstrual flow is about six ounces, we may infer that the fluid evacuated represented approximately nine monthly periods, and that the girl began her menstrual life at the age of thirteen years and eight months.

After operation the patient was kept in bed for five days and the vagina was carefully syringed with carbolic water. There was no febrile reaction and no evidence of sepsis. Twenty days after operation a normal, painless, and free menstruation took place, lasting six days. Three days thereafter I found that the vagina had contracted a good deal, but was still quite capacious: the vaginal walls were now more or less thrown into folds, and gave off a thin, glairy secretion: the uterus was normal in size and position.

These cases of congenital hymeneal atresia are rare. Carl Braun observed only four cases in his extensive experience, and Lombe Atthill, Master of the Dublin Rotunda, only one. Among careful, intelligent people the anomaly should be recognized early; and when thus recognized, and aseptically treated, the results should be good. In neglected cases, however, the uterus and Fallopian tubes may become distended, blood may thus escape into the peritoneum, and fatal results ensue. In these cases, too, of hæmatometra and hæmatosalpinx, there is danger of rupture of the tube either by over-distention or by the force of a rapidly contracting uterus after the hymen is incised. To avoid this latter danger it is prudent to make at first only a small opening in the hymen, thus allowing the fluid to escape very slowly, and also to avoid all pressure over the uterus, either by the hand or by the abdominal bandage which has sometimes been advised. The greatest danger in all cases of menstrual retention from hymeneal atresia, and the one most fatal in former days, can now most happily be averted by rigid surgical asepsis.

It is probable that in earlier times these cases of menstrual retention were sometimes overlooked and the patient treated with iron and the various emmenagogues until distressing symptoms demanded a physical examination. Sometimes the hymen has ruptured

spontaneously, and a natural cure thus resulted. Mitchell² has recently reported the case of a girl of sixteen who had never menstruated, and who had had monthly attacks of spasmodic pains in the lower part of the abdomen, irritation of the bladder, and a constant feeling of bearing down, associated with abdominal enlargement. During an attempt at vaginal examination the hymen was ruptured, a large amount of retained menstrual flow gushed out, and recovery followed.

II.

Mrs. H., aged thirty-five, who had borne one child several years before, was referred to me in the autumn of 1893, by Dr. J. H. Woods, of Brookline. She had been for some time in poor general health, and there was well-marked nervous debility: the pelvic symptoms were backache and a constant feeling of bearing down. Vaginal examination revealed a second degree of retroversion with old adhesions, a slight laceration of the cervix requiring no treatment, and two cysts of the vaginal wall. The cysts were seated, the one on the anterior wall just in front of the cervix, the other on the right posterior wall at its upper third: the size of the two cysts was about equal, that of a large horse chestnut or small hen's egg. These cysts had probably been growing for several years; but it was only in the past year or so that the patient had been conscious of some obstruction in the vagina.

It was obvious that what was most needed in this case was general treatment directed to the neurasthenic condition; and incidentally it was thought best to free the uterus, if possible, and restore it to its normal position. The cysts probably added little to the patient's discomfort, except in so far as possibly to increase the sense of weight in the pelvis and to interfere somewhat with physiological functions. It was evident, however, that their presence would interfere with measures to raise the uterus and the subsequent wearing of a pessary; and it was reasonably probable that before long they would reach such a size as to occlude the lumen of the vagina. It was therefore thought best to remove them. Under ether anæsthesia the cyst walls were freely laid open, there appearing to be no sac which could be dissected out. The contents of the cyst on the right posterior wall were of a thinish, mucoid character, of a light chocolate color, and without odor: those of the cyst on the anterior wall, thick, viscid, and almost semi-solid, of albuminous color, and likewise without odor. This latter material was submitted to the examination of Dr. W. T. Councilman, who reported as follows: "Contents of cyst consist of a glairy mucus, enclosing great quantities of so-called Drysdale's corpuscles and large leucocytes filled with fat granules. It is very probable that the cyst had an epithelial lining, and that these Drysdale's corpuscles are the nuclei of cells which have been destroyed."

The cyst cavities were gently curetted, cleansed with Dobell's solution and weak corrosive, and lightly packed with iodoform gauze. After ten days the cavities had markedly shrunk, there was very little mucous discharge and the openings were still patent: the patient was then sent home for general treatment preparatory to dealing with the adherent retroversion.

Mucous cysts of the vaginal wall are fully treated in the text-books, and I am able to contribute nothing

² British Medical Journal, December 16, 1893.

new to the knowledge of the subject. They must be regarded as somewhat rare, although some observers, notably Lee, of New York, consider them fairly common: in an experience of sixteen years I have met with but this one case. They occur, as a rule, singly, more rarely two or three at one time. The anterior wall of the vagina is the most frequent seat, the lateral wall the least common. In sixty-six per cent. of the cases the cyst is situated between the middle of the vagina and the vaginal introitus, and when thus seated may simulate rectocele or cystocele: in my case both cysts were at the upper third of the vagina. The cysts may vary in size from that of a pea to that of the fist: isolated cases are also reported of still larger cysts; but they are usually discovered by the time they reach the size of a hen's egg. They may be superficially or deeply seated: in my case both cysts were superficial. The contents of the cysts may be thin, resembling that of hydrocele fluid, and of reddish, brownish, greenish or chocolate color; or they may be thick, viscid and albuminous.

Opinion is still divided as to the existence of glands in the vaginal wall; but the weight of authority seems to be that in all probability there are no true glands, but what are called vaginal crypts. Vaginal cysts are probably not, therefore, retention cysts properly so called, like wens or cysts of Bartholin's glands, but are developed in the vaginal crypts, which are lined with flattened epithelium, and which have in some way become occluded, either by inflammatory processes or by epithelial plugs. This subject is fully discussed in an able paper by Rutherford, which is the latest contribution I have seen.

Vaginal cysts, as a rule, grow very slowly, and when small cause no symptoms: small cysts are therefore discovered only by accident. Large cysts may cause uterine displacements, may interfere with the bladder or rectum and cause various pressure symptoms, may make coitus difficult or impossible, and, when seated low, may protrude from the vagina and cause discomfort: they may also constitute an obstruction in labor.

The best treatment of vaginal cysts of any size is undoubtedly enucleation; but this is often difficult or impossible when the cyst wall is thin or the cyst is deeply seated. In such cases free incision and evacuation is the most reliable measure, followed by curetting and packing with iodoform gauze: it is well also to excise a small portion of the cyst wall to prevent closure of the incision, after the patient has passed from observation.

These tumors should be recognized without difficulty; but Winckel points out that they may be mistaken for cystocele, rectocele or small ovarian cysts. Careful examination, however, will usually remove all doubt, and doubtful cases should be aspirated before incision. In large cysts there is well-marked fluctuation.

III.

A. C., aged thirty-two, single, a bookkeeper by occupation, consulted me in November, 1891, and gave the following history: The general health had always been fairly good, and the menstrual function normal; she had suffered more or less with hæmorrhoids, and twelve months previously had been operated on for the cure of a fistula in ano. Since the operation she

had suffered with soreness about the vulva, and also with incontinence of intestinal gases and semi-liquid discharges. It was from this last annoyance that she especially sought relief.

Physical examination disclosed a short fistulous tract extending from the lower border of the sphincter ani to an opening about two inches to the left of the anus: further, the sphincter was entirely laid open at its upper left border, and a gaping sulcus extended from this point upward toward the left, along the inner border of the left labium majus to a point opposite the lower third of the left labium minus. There was a small button-hole opening through the left nymphæ: the hymen was intact. The symptoms and lesions presented were essentially those of a complete rupture of the perineum, although the vagina was in no way involved. It was obvious that there had existed a fistula in ano extending from within the sphincter upward and to the left between the labia, that this fistula had been laid open, and that the sulcus had subsequently failed to unite, although the surfaces had cicatrized.

Through the kindness of Dr. E. J. Forster, who was then on duty, the patient was admitted to the Boston City Hospital, and I operated to close the sphincter and restore the integrity of the parts. The necessary denudation was made, the rectum was closed in with catgut sutures, and the sulcus above with silver wire. The superficial fistula in ano was successfully treated with the elastic ligature. The wire sutures were removed on the tenth day, good union had taken place, the deformity of the parts was removed; and on discharge, two weeks later, the patient had entire control of the sphincter ani as regards both liquid feces and intestinal flatus.

This case is unique in my experience, and I have never seen a similar one reported. Should a case of recto-vulvar fistula ever present itself to me before the sinus had been laid open I should adopt the method of treatment proposed by Dr. E. W. Jenks, of Detroit, in 1883,* for the cure of fistula in ano. In view of the fact that in so many cases treated by incision alone the sphincter ani fails to unite, and the deplorable condition of incontinence of feces and flatus thereby ensues, Jenks recommended the following method of procedure: The sinus is laid open, care being taken to incise at right angles to the sphincteric muscular fibres; the so-called pyogenic membrane and all adjacent abnormal tissues are dissected away; and the sulcus is then closed with buried sutures passed entirely around the fistulous tract, the sphincter to be closed as in cases of complete rupture of the perineum. Dr. Jenks does not claim that this method is applicable to all cases of fistula in ano; but it would seem to be especially applicable to cases like the one above reported.

IV.

Mrs. A. D., aged twenty-seven, first came under my observation just prior to her first labor in 1891. She was a fine specimen of womanhood, well developed, accustomed to long walks, and, with the single exception to be presently mentioned, in robust general health. Early in her pregnancy, in place of the morning nausea and vomiting so commonly observed at this time, she began to be troubled with salivation. This symptom gradually increased in severity, interfering

* Transactions of the Obstetrical Society of London, 1892, page 364.

* Transactions of the American Gynecological Society, Vol. 8.

with her comfort by day, but especially disturbing her at night. In fact, the flow of saliva finally became so profuse at night that the patient dared not lie down for fear of choking, but sat bolstered up in bed with a towel placed to receive the saliva. She was thus able to sleep but little, although towards morning the flow diminished somewhat, and she was enabled to sleep for two or three hours. In spite of the loss of sleep, however, the general health continued good, and the appetite was unaffected. The submaxillary glands were markedly enlarged and the contour of the face thereby distorted; the eyes, too, were somewhat heavy from loss of sleep, but otherwise the patient looked as well as usual.

During all this time the lady had been under the care of a well-known and able physician, who had tried all the drugs recommended for excessive salivation without appreciable effect. The patient said she had received more than a dozen prescriptions. It did not therefore seem worth while for me to attempt any further treatment. I found that the urine was markedly diminished in amount, without other abnormality, however. This diminution was undoubtedly due to the great derivation of water through the salivary glands, and I advised the free use of Apollinaris or lithia water, which increased the amount of urine somewhat. The labor was in no way remarkable: the os uteri was fully dilatable after twenty hours of first stage labor; but the head did not descend, and after two hours of fruitless maternal effort I delivered a ten-pound girl with high forceps and axis-traction rods. During the next three days salivation occurred two or three times, the flow lasting only a few minutes; it did not appear after the third day, when lactation was fully established; from this time the convalescence progressed normally, and mother and child were discharged well.

Early in 1893 this patient became pregnant again, and at the end of the second month salivation began again as in the first pregnancy: there was no morning sickness. By the fifth month the flow of saliva had become so excessive as to cause great discomfort and loss of sleep; but, as before, the general health continued good. In view of her former experience, the patient was indisposed to submit to drug treatment, especially as I could offer no assurance that any treatment would prove effectual. As before, lithia water was found to be the most refreshing drink for the swollen gums and oral mucous membrane. Labor began just 280 days from the first coitus after the last menstrual period, and with the invasion of labor pains salivation ceased. The labor was uneventful, except that as before it was necessary to deliver with high forceps, the child, a boy, weighing ten pounds. On the second day there was some return of salivation, and with the establishment of lactation the salivary flow did not cease, as in the former pregnancy; on the contrary, it continued for two weeks more or less profuse, never absent for an entire day, and sometimes sufficient in amount to cause vomiting when the patient was recumbent. After two weeks the flow gradually diminished in amount; but it did not cease altogether until the end of three months. Aside from this discomfort the convalescence was normal, and mother and child were discharged well.

I have met with but one other case² of excessive

salivation in pregnancy, and that was seventeen years ago when I was a medical student. My experience is therefore that of others, that excessive ptyalism of pregnancy is a very rare affection. Winckel, in his text-book of midwifery, says that salivation is mostly associated with extreme nausea and vomiting; but these latter symptoms were absent both in Dr. Richardson's case and in my own. The disorder is probably a reflex neurosis, like many of the cases of uncontrollable nausea and vomiting. The amount of the salivary flow in twenty-four hours may reach several quarts and seriously impair the general health. In some cases of ptyalism, as in some of nausea and vomiting, the disorder may cease spontaneously in the fourth or fifth month; in others, as we have seen, it may continue throughout pregnancy, and cease soon after the birth of the child or on the establishment of lactation. Charpentier³ mentions seven cases in which ptyalism began with the pregnancy (as in Richardson's case), and persisted after delivery, once fifteen days, once eighteen days, twice for two to three weeks, and three times in the same woman for from three to four months.

In regard to the treatment of this affection, while many drugs are recommended by various writers, reliance can be placed upon none. Galatin truly says that pregnancy salivation "is apt to resist remedies." Astringent mouth washes of tannin or quassia may palliate, but cannot be expected to cure. Charpentier recommends the frequent use of brandy as a gargle, and the keeping in the mouth of small pieces of dry, bitter, orange peel. Other recommended remedies are pilocarpin (perhaps on the *similia similibus* theory), iodide of potash, fluid extract of viburnum prunifolium, belladonna, and atropia, the latter being best used by hypodermic injection near the affected glands. But if the affection is a reflex neurosis, it would seem that nerve sedatives would hold out most promise of successful results. Schramm is said to have cured a case in 1886 with bromide of potash, after the iodide and pilocarpin had both failed; but if I remember rightly Richardson used the bromides in his case, to which I have alluded, without apparent effect. If I were to meet with another case, however, I think I should place most reliance on bromides and on large doses of chloral hydrate, the latter exhibited preferably by rectum.

REMARKS ON SURGICAL SPLINTING.¹

BY EDWARD A. TRACY, M.D., BOSTON, MASS.

THAT illustrious surgeon, Frank Hastings Hamilton, whom I delight in quoting — for his work on "Fractures and Dislocations," the first of its kind in the English language, does honor to American surgery — he, speaking of the ordinary manufactured wooden splints, said: "I wish at once, and for all, to disclaim any intention of giving even a qualified approval of any of those carved, polished, and generally patented wooden

¹ Read before the Malden Medical Society, January 29, 1894.

Richardson, at that time instructor in clinical obstetrics, was summoned to my assistance and delivered with forceps a face presentation, M. D. P. He recognized the patient as one whom he had been treating for salivation in the out-patient department of the Massachusetts General Hospital, and who was also affected with excessive ptyalism in her former pregnancy. In this case salivation ceased within half an hour after delivery. Dr. Richardson's report of this interesting case may be found in the Boston Medical and Surgical Journal for July 12, 1877.

² Cyclopædia of Obstetrics and Gynecology, vol. II, page 67.

³ This case was assigned to my charge in 1877 by the Obstetrical Department of the Harvard Medical School. Prof. William L.

splints, which are manufactured and sold by clever mechanics, and which one may see suspended in almost every doctor's office, whether in the city or in the country. Constructed with grooves and ridges, and variously inclined planes, for the avowed purpose of meeting a multitude of indications, such as to protect a condyle, to press between parallel bones, to follow the subsidence of a muscular swelling, etc., they never meet exactly a single one of these, whilst they seldom fail to defeat some other indication of equal importance. . . . If carved wooden splints are employed, they ought to be made especially for the case under treatment."

These strictures apply, it seems to me, with somewhat lessened force to the metal splints we frequently see nowadays. Hamilton further states his preference for strips of wood cut to the proper length and width by the surgeon, and so padded as to fit the inequalities of the limb treated. This surgeon was an adept in the use of gutta-percha for splinting; and the point to note is that whatever he used, he made his own splints. Most surgeons, I believe, think as Hamilton did in this matter; and Dr. Henry O. Marcy's dictum, "The surgeon must make a splint to fit the limb—and not the limb to the splint," aptly defines the proper practice in surgical splinting.

The subject of surgical splinting is a vast one, whether looked at from an historical or a practical point of view. Had I the time and qualifications needed, and you the patience, it might be clearly shown you that surgical splinting, like navigation and printing, had attained perfection undreamed of, in the happy era preceding that of the Chinese philosopher Confucius. But doubtless you will be better pleased if, fancy being restrained, the practical aspect of the subject be dwelt upon. Indeed, I shall use further restraint, and confine myself to remarks on surgical splinting as exemplified in the use of my wood-pulp material, and that, I hope in a manner interesting and profitable to you all.

First, the material and method used shall be described, and later a variety of splints made in accordance with this method shall be shown you; finally, if time permit, I shall demonstrate the method by making a splint before you.

In describing the material, time is saved by quoting from a paper (to be published later) contributed by me to the recent Pan-American Medical Congress.

THE MATERIAL.—The basis of the material is wood-pulp made preferably from the crushed fibre of the poplar tree, and rolled in sheets in such fashion that the broken fibres intertwine in every direction and loosely, so that an increase of plasticity is thus given to the product. These sheets are further strengthened by having a fabric introduced between the layers of the pulp, or by interweaving with the short, crushed wood-fibre, a long jute or other tough fibre.

The sheets are rolled of different thicknesses, for adaptability to all splint conditions. For convenience I shall designate the thickness by number, each unit representing a thickness of one millimetre: thus sheet No. 1 represents the material with a thickness of one millimetre,—sheet No. 2, with a thickness of two millimetres, and so on.

Characteristics of the Material.—The chief characteristics of this material are stiffness or rigidity when dry, and plasticity when moist. Its rigidity can be increased *ad libitum* by the use of a silicate solution as a moistener. Its plasticity has a limit. The limit is rarely experienced, and only when moulding the material over certain complex curved surfaces. To exemplify: a splint cannot be directly

moulded over the ankle-joint anteriorly, for there are two large curves in opposite directions to be followed simultaneously—the convex curve from malleolus to malleolus, and the concave from above downwards over the leg and instep. This difficulty, when met, can be obviated in various ways. I shall mention three of them. Take the case of the ankle-joint: an anterior splint is required for it. The proper-shaped blank shall be cut from sheet No. 1, and moistened with one of the solutions described later. It then should be applied to the limb, care being taken to keep its outer border in contact with the skin, while the superfluous material over the anterior of the joint should be pinched between the thumb and forefinger, and all of it laid or pressed over to one side; a bandage should be singly applied to perfect the moulding of the splint. This method of "pinching and folding over" has an important application in the making of spinal jackets. A second method consists in cutting away the superfluous material, in this case an elliptical figure, and bringing the edges of the cut portion together, to retain them so by means of a strip of the material fastened over the cut edges. A third way is to cut a blank for each important curve and after moulding to properly unite them.

The material possesses, besides the above characteristics that *desideratum* of a splint material—extreme lightness. Its cheapness also deserves a passing mention.

MOISTENERS.—Water or a stiffening solution can be used to moisten the material.

Water.—The advantage of water is its omnipresence. A serviceable splint can be made with its aid. Such a splint should be protected from perspiration or other moisture, lest it be softened and its usefulness destroyed. It can be so protected by a covering of oiled paper or silk, mackintosh, or best by a coat of varnish.

Silicate Solution.—A stiffening solution having several qualities to recommend its use is that of silicate of potash (silicate of soda is almost as serviceable). Any desired degree of rigidity can be imparted to a splint by using this solution, the amount of rigidity depending on the strength of the solution. A splint rendered rigid in this manner, is not affected by perspiration, nor indeed by momentary contact with fluids, as in washing. Another advantage, especially in cases of compound fracture, is that this solution renders the splint antiseptic. In practice, the solution of silicate of potash generally sold for surgeon's use, and further diluted with water, can be employed. (The commercial solution spoken of in this paper is regarded as a 100-per-cent. solution, and the percentage solutions spoken of in this paper are to be made by diluting the commercial solution with the proportion of water called for by the percentage: thus a 70-per-cent. solution is made by mixing 70 parts of the commercial solution of silicate of potash with 30 parts of water. The commercial solution should have a specific gravity of 1.3 to 1.4.)

Dextrin Solution.—Another useful stiffening solution is that of dextrin, in the proportion of about eight ounces to a pint of water. This solution adds some tenacity besides stiffness to the material treated with it. A splint made with its aid can be remoistened with water and remoulded, quite an advantage in cases where from subsidence of swelling or other cause, a closer approximation of splint to the limb is desired. In practice, dextrin (to be had of paint wholesalers) can be carried about in powdered form, and a solution in water extemporized when needed. An addition of eight grains of corrosive sublimate to a pint of the dextrin solution will render it antiseptic.

MOISTENING PROCESS.—A few words descriptive of the proper manner of moistening the material. The aim should be to get barely sufficient moisture into the material to render it semi-plastic. If more moisture be absorbed, it becomes more difficult to maintain the moulded splint in the desired shape while drying, and also unnecessarily lengthens the time required to dry the splint. I find the best way of moistening the splint blank, is to apply the fluid used, on each side of it, alternately, by means of a flat paste-brush. A little practice will enable us to judge the precise amount of moistening best suited for our purpose.

DRYING.—The time required for drying the moulded blank varies, for the different sheets employed, from ten to forty minutes; the thicker sheets, holding the more moisture, require the longer exposure to heat to drive it out. Any source of sufficient heat can be employed; a good kitchen fire is very efficient and, generally, convenient. While the splint is drying it is serviceable to have yarn or string wound around the moistened form after its removal from the body, to aid it to maintain the desired form, until drying permanently fixes it.

FIG. I. A Claviculo-Scapular Splint.

Having thus described the material and method used, instead of quoting further the dry technique for the various head, trunk, upper and lower limb splints, I shall show you some made in accordance with that technique, "the observation of one of which is better than a large demonstration of words," to quote old Isaac Walton.

The most of the splints here shown were exhibited at the Columbian Exposition; your Society, and I am grateful for the honor, has been the first to give me an opportunity to display and explain them to brother practitioners. [Splints for various parts of the body, all of them moulded on the living subject, were shown and discussed; the following three are selected for illustration here.]

A CLAVICULO-SCAPULAR SPLINT.

This splint is part of an apparatus devised for the treatment of dislocation (upwards) of the acromial end of the clavicle. The apparatus is fully described in the *Boston Medical and Surgical Journal*, Vol.

CXXXVIII, p. 186. An apparatus for fracture of the clavicle has been devised on the same principle, that is, to regard the shoulder as a pyramidal body, and to

FIG. II. A Thumb Splint.

so treat it. In a fracture, however, there is such short bone leverage for effective pressure, that a modification is introduced by which the apex of the pyramid is raised upward and backward, and by suitable splinting fixed effectively in the desired position.

A THUMB SPLINT.

This splint is intended for fixation of the thumb, including its metacarpal bone. It embraces the thumb, that portion of the dorsum of the hand shown in the engraving, and somewhat more than the thenar eminence of the palm, care being taken to keep below the cross-palm lines that mark the region of the meta-carpo-phalangeal joints, so as not to hinder finger motions.

A SPINAL JACKET.

The blank for this splint is of the simplest pattern, having width sufficient to envelop the patient's body once and a quarter around, and its length governed by the amount of spine we wish to control. This particular jacket was made for and worn by a boy of six years.

It was moulded on the boy's body and completed at his home in less than forty minutes. The jacket's edges are covered with chamois skin glued on. The straps are of chamois skin also, and this material was used because of the ready manner it can be attached

FIG. III. A Spinal Jacket.

to the jacket, and its toughness and friction preventing the giving or slipping of a bow-knot.

Before attempting a demonstration of splinting by this method, I must state that it is handicapped by the amount and quality of the material at hand. That manufactured so far has been finished by hand-labor at the pulp mill. It has been distributed among Boston surgeons, several of whom have kindly signified to me their pleasure in testing it. The supply is now exhausted, I hope not for long. Mr. Charles H. Fisk, of Manchester, N. H., the gentleman who has undertaken to put the material on the market, has written me that machinery will be constructed to manufacture it cheaply and expeditiously.

[The making of a palmar forearm splint was here demonstrated. The splint meets the indications which Cheever emphasizes in the treatment of a Colles' fracture. He says: "The important point would seem to be . . . not to press the back of the wrist down in such a way, by splints, that we shall lose sight of this arch, which is so marked, under the radius. . . . This arch must be well supported. . . . The splint should terminate at the head of the metacarpal bones, and the thumb and fingers should be left free."²]

In concluding, fellow-practitioners, I thank you for your kindness and energy in braving to-night's snow-storm, to meet here; and I ask you, if pleased with this splint material, to take hold of it and develop its various applications, which have been so briefly hinted at; then, perhaps, in later years we can all look back on work done, and done well, and feel that we have done some little to advance surgery — American surgery.

Clinical Department.

A CASE OF MYXŒDEMA.

BY ROBERT E. BELL, M.D., LOWELL, MASS.

THERE has been so much written on this subject, and it is so prominently before the profession, that I wish to report my one case, as it has presented some features that I have not seen mentioned.

Mrs. B., fifty-four years of age, consulted me first January 7, 1894. Family history good. Father and mother both lived to be almost seventy; two brothers and four sisters living. She dates her symptoms from about eighteen months ago. She comes to me because she cannot see to read, and thinks her glasses need changing. $V=\frac{1}{2}$; glasses do not improve her vision. Ophthalmoscopic examination simply shows the fundus somewhat paler than normal.

Patient says that about eighteen months ago her face and hands began to bloat, and she had difficulty in keeping hold of objects in her hands, was constantly dropping dishes, etc. Then her limbs began to swell; and finally she noticed she could not get her clothes on alone, her arms were so useless. She had become very sensitive to cold. Her hands and arms pained her so she could sleep but a few hours. Was dizzy, and felt like falling if she attempted to walk. No appetite. Urine at times was very heavy and almost black. She could not go up stairs without getting out of breath. When she came to me, there was pallor of

the face and a puffiness about the eyes. There was œdema about the ankles and legs. The skin of the hands was dry and rough. The hair had no lustre. She talked very slowly and deliberately, and walked as though completely tired. Examination of urine was negative.

Supposing I had a case of myxœdema to deal with, I ordered the thyroid extract of Parke, Davis & Co., in doses of five grains twice a day. At the end of one week patient was better, but complained of some nausea, and pain in her back and legs. I decreased the extract to three grains twice a day, and kept it up until the middle of February, then reduced it to about two grains a day.

At the present time she considers herself well. I certainly never saw a more marked improvement in any patient. She eats well, sleeps well and breathes well. Her vision is now all right with the lenses suited to her age.

Medical Progress.

REPORT OF PROGRESS IN GYNÆCOLOGY.

BY F. H. DAVENPORT, M.D.,

Instructor in Gynæcology, Harvard University.

THE CAUSE OF PERITONEAL ADHESIONS AFTER ABDOMINAL SECTION.

WALTHARD¹ has conducted a series of experiments in the Pathological Laboratory of University College, London, to ascertain the cause of peritoneal adhesions after abdominal section, with a view to discover the way to avoid that complication. He found that prolonged contact of normal peritoneum with atmospheric air caused necrosis of the superficial layer of cells. This injury, even when strict asepsis is carried out, favors the formation of adhesions. It speaks in favor of rapid operating, but many gynæcological operations and procedures for disease and damage to the intestine cannot be performed quickly; hence there must always be danger of peritoneal adhesions when the course of the case is aseptic, and of suppurative peritonitis when accidental infection occurs. The great aim of the operator is to make sure that the peritoneal cavity is thoroughly cleared of all fluid or semi-fluid material by the usual "toilet." In short, the serous membrane must be kept from the contact of fluid, but not allowed to become dry by exposure to air. This Walthard calls "dry asepsis."

When the cavity cannot be kept dry, as in many long operations, "moist antisepsis" is required. In other words, the peritoneum is flushed out with water at 100° neutral, and preferably containing chloride of sodium. The loss of its shiny appearance is the evidence that the serous membrane is becoming dry.

URETERO-VAGINAL FISTULÆ.

Hochstetter² has been able to find records of thirty-nine cases of uretero-vaginal fistulæ, of which twenty-three were caused by difficult labors, ten followed total extirpation of the uterus, two the opening of a pelvic abscess, one the spontaneous breaking of an abscess, one from ulceration caused by a pessary, and in one case the cause was not given.

The frequent performance of vaginal hysterectomy

¹ Lectures on Surgery. By David W. Cheever, M.D. See Lecture X, Boston Medical and Surgical Journal, vol. cxxix, p. 2.

² Correspondenz. Blatt f. Schweiz. Aertze xxxiii, 1893, reported in British Medical Journal, December 2, 1893.

³ Arch. für Gyn., xiv Band, 1 Heft, 1893.

makes the study of fistulæ from this cause of interest. Ligature of the ureter of one side is difficult of recognition in the first days after the operation, since there is often from other causes a diminution in the amount of the urine. The cystoscope, or catheterizing the ureters, would assist materially in making a diagnosis. Ligature of both ureters is recognized by absolute anuria. If such a diagnosis is made early, the immediate removal of the ligatures may result in a restoration of the function of the ureters and the avoidance of a fistula. Two such cases are referred to.

The diagnosis of a ureteral fistula is an easier matter. The patient loses only a part of the urine, about a half, the bladder is intact, as shown by injecting it full, and the sound does not pass from the fistula into the bladder, but from the bladder through the fistula into the vagina.

The treatment of such a fistula is, in the first place, by cauterization, care being taken not to cause so much swelling as to close the ureter. If the ureter is not wholly cut through cure may follow, and several such cases have been reported. If this fails, operative treatment should be tried. Simon advised changing the ureteral fistula into a uretero-vesico vaginal fistula, and then closing, but his attempts failed. Landau suggested passing a thin catheter from the vagina into the ureter, carrying the free end through the lower segment of the ureter into the bladder and out through the urethra, refreshing the tissues on both sides of the catheter and uniting them. There have been several successes by this method.

A modification of this procedure by Schede consists in making a vesico-vaginal fistula, and then turning the open end of the ureter into the bladder. The details of this method should be read in the original in the *Centralblatt für Gynäkologie* for 1881, No. 23. A case operated on by Schede, and one the account of which is given in the article under review and three by other operators were successful.

If such attempts at cure fail, there are two courses open, the closure of the vagina below an artificial vaginal fistula, and the extirpation of the kidney of the affected side.

VENTRO-FIXATION OF THE UTERUS.

Napier and Schacht^a divide ventro-fixation into two great varieties, indirect and direct. The first fixes the uterus by means of its ligaments or the pedicle of an ovarian cyst, etc., in the course of another operation; the second requires suturing of the uterus itself. Direct corporeal uterine fixation may be either lateral or median. The authors favor the median method, and the essential feature consists in passing three sutures through the edge of the rectus muscle, the fascia, peritoneum of the left side, the uterine wall, and the same structures of the right side, one at the fundus, one as near the intra-peritoneal cervix as possible, and one midway between these.

The conditions which justify such an operation are when uterine retroflexion or procidentia occasions such symptoms as unfit a woman for her life-work, provided other forms of treatment and minor operative measures have proved non-curative. Age is an important factor. Of twenty cases operated on by the authors, seventeen were under forty years of age. There were eleven cases of retro-displacement, nine of prolapse. Ten had been done long enough before the report to judge

of permanent results, and of these only one was a failure, and that was due to the dragging of cervical fibro-myoma. There were extensive adhesions in five cases, in fifteen there were none or they were easily separated. Two deaths occurred in the series, one from sepsis and one from hæmorrhage and shock.

CONSERVATIVE TREATMENT OF DISEASES OF THE UTERINE APPENDAGES.

Pozzi⁴ refers in this paper, in addition to operations on the tubes and ovaries themselves, to methods of treatment of the uterus diseased at the same time as the tubes, which have for their object the cure of the latter, such as curetting, cauterization and electricity. Such measures Pozzi believes may be useful in the first phases of acute catarrhal salpingitis, but illusive in pus cases or in chronic cases where the walls are thickened. Massage and electricity should be applied to diseased appendages only in chronic cases where the tubes contain no liquid. The conservative operation which has been proposed in cystic salpingitis in order to induce the evacuation of the liquid by dilatation of the uterus and of the ostium internum of the tubes, is dangerous on account of the likelihood of provoking inflammation of the neighboring peritoneum and is usually impracticable by reason of the extensive obliteration of the tubes in the vicinity of the uterine cavity.

In discussing the main topic of the paper, namely, operations bearing directly upon the ovaries or tubes for removing the diseased and respecting the healthy part, he considers two procedures, resection and ignipuncture of the ovary.

With regard to partial resection of the Fallopian tubes, Pozzi eliminates it from the number of conservative operations. He believes that once having been attacked by acute inflammation, it has become definitely incapable of fulfilling its physiological rôle. The rôle of the Fallopian tube is not that of an inert duct; it is essentially active; the integrity of its texture, the persistence of its vibratile epithelium and its contractile fibres are conditions indispensable to its function. Therefore an inflammation of some duration must surely destroy or definitely paralyze these active elements.

It is entirely otherwise with the ovary. It is well known that a small quantity of ovarian tissue suffices to assure the regularity of menstruation and to permit fecundity, hence there are more than theoretical considerations in favor of partial resection of the ovary. The persistence of menstruation is constantly remarked if a fragment, however small, is left, and several observations prove that its fecundity is preserved.

It remains to be determined in what cases of lesions of the ovary a partial operation can be made, and to decide the nature and technique of this operation. The first general consideration is that whenever the Fallopian tube is healthy and the ovary alone diseased, it is wise to preserve a part, and only at the last extremity make a total sacrifice.

The most favorable cases are those in which the diseased process has affected one region of the ovary leaving an entire segment of the organ intact. A typical lesion is an isolated cyst, in which case, after it has been ascertained that the tube is completely permeable by the passage of a stylet, the surgeon performs the resection of the diseased parts by two incisions

^a British Medical Journal, October 14, 1893.

⁴ British Medical Journal, September 16, 1893.

which circumscribe a cuneiform segment. The two lips of the wound are reunited by a continuous suture in catgut. Resection may also be employed in cases of microcystic degeneration, in which the disease has left a zone of ovarian tissue intact. It is frequently found that a large part of the organ is thus affected, whilst in the region of the hilum, a band of tissue exists untouched by disease. An incision can be made along this line, removing the greater part of the ovary, but preserving the base of the organ. Pozzi, in addition, in cases where it has been necessary to liberate the Fallopian tube by tearing off adhesions, fixes the ostium of the tube upon the ovarian stump by means of a few points of suture, in order to prevent the tube from falling away from the rest of the ovary and contracting adhesions.

Lately, Pozzi has practised ignipuncture instead of resection. He considers it more expeditious and doubtless more efficacious than resection. When the ovary presents dispersed lesions such as cysts of small volume, they are opened successively by the small knife or thermo-cautery, and burned on their internal surface. Where there is diffuse ovaritis it is advisable to make the point of the cautery penetrate rather deeply into the oedematous stroma. He has no doubt that the actual cautery has a distinct influence in producing an energetic melting of the chronic inflammations.

In answer to the objection that the cautery would be liable to produce sclerosis, Pozzi says: "Assuredly this might be the case were the cauterization followed by the falling away of the eschar from suppuration and granulation. But in the interior of the peritoneal cavity the process is quite different; it is essentially aseptic. The eschar is reabsorbed, molecule by molecule, without inflammatory process or embryonic proliferation susceptible of becoming a nodule of fibrous tissue."

The practical results in Pozzi's cases have been satisfactory. He has performed resection of the ovary six times and ignipuncture eight times. All the patients recovered, and in all, either immediately or later, the pains ceased or were greatly diminished, and in those who before had suffered from menstrual irregularities there was improvement. One patient became pregnant, in whose case he made twelve deep points of ignipuncture in the left and eleven in the right ovary. The ovaries were white, smooth and enlarged and affected with diffuse ovaritis.

His experience is recent and extends over a period of a little more than two years. The results are, however, very encouraging, and taken together with those of Martin, may serve to encourage operators in a new path.

THE SO-CALLED "CONSERVATIVE OPERATIONS" ON OVARY, TUBE AND UTERUS.

The partial operations on ovary, tube and uterus in case of tumors and other diseases, have, according to Martin,⁶ found so little favor that he has been led to call attention to them again. The resection of one ovary after extirpation of the other, in particular puncture of hydropsical or hemorrhagic follicles, has been performed by Martin twenty-seven times; of twenty-four operated on in the last method, eight became pregnant later. As soon as the disease of the ovary has left no functionally-active ovarian tissue and especially where a purulent process has been recognized

the extirpation of the whole ovary is indicated; for the small number of cases in which there is chronic oöphoritis or circumscribed new growths, Martin recommends partial resection. The resection of occluded tubes after extirpation of the other diseased tube Martin has performed forty times; one woman conceived later. Of the one hundred and forty-one enucleations of intra-parietal myomata, twenty-six women died; of the one hundred and fifteen that lived, five developed new tumors and two conceived again.

Martin claims that these conservative operations offer no greater dangers than the radical, that the women are almost universally freed from their sufferings and remain so, that relapses or affections of the resected organs rarely occur, that the feminine functions remain intact, that pregnancy is possible even with such partially preserved organs and that finally the birth occurs without especial danger.

ENDOMETRITIS IN THE MENOPAUSE.

Jacobs⁶ is opposed to the view that the menopause has a curative effect on endometritis and leucorrhœa, that being the exception and not the rule. He describes the degenerative changes of the genitalia in the menopause, the symptoms of endometritis and their differential diagnosis from carcinoma, and calls especial attention to the fact that even in non-malignant disease the discharge may be foul-smelling. As general symptoms he mentions pallor, wasting away, indigestion and obstinate constipation; occasionally neuralgia and mental disturbances occur. Chronic eczema, urticaria, acne, pruritus vulvæ and mucous polypi in the uterus are frequent accompaniments. Usually the disease has existed before the menopause. As therapeutic measures the author advises at first building up the general health, then curetting followed by local treatment.

ENDOMETRITIS PURULENTA SENILIS, SEU ATROPHICANS.

Patru,⁷ under this name, describes a disease which has been noticed by only a few authors, notably Fritsch. It has clinically, as well as pathologically, a resemblance to ozæna and occurs in women over sixty, especially in those who suffer from cardiac affections. It can be caused by bacteria of a type very little studied, which develop in the atrophied mucous membrane and cause a more or less foul purulent discharge which occasionally is bloody. In the discharge are found various forms of bacteria, red and white blood corpuscles and a polygonal, atypical, uterus epithelium. The discharge is either constant and scanty, or intermittent and profuse. The patients complain of moderate pain in the back lower abdomen, the uterus is usually normal in size and moderately tender. The complexion is sallow and can, in connection with the fetid discharge, simulate malignant disease, although the cervix is small and soft and shows no swellings or ulcerations.

The vagina may be inflamed and adhesions of the walls may occur; perhaps the little studied vaginitis adhesiva is only a secondary affection and result of senile endometritis. The prognosis is favorable and the disease gradually disappears with age; whether malignant degeneration occurs is not known. The thing to be feared is sepsis from retained secretions and cachexia from chronic secretion of pus. To avoid

⁸ Deutsch. Med. Woch., xix, 30, 1893, reported in Schmidt's Jahr.

his the treatment should consist in dilatation of the cervical canal, curetting, cauterization of the inner surface of the uterus and daily vaginal injections.

Reports of Societies.

CAMBRIDGE SOCIETY FOR MEDICAL IMPROVEMENT.

ALBERT E. TUTTLE, M.D., SECRETARY.

A MEETING of the Society, February 26th, with DR. HENRY O. MARCY in the chair, was specially devoted to a discussion of

THE MALARIAL DISEASES OF THE CHARLES RIVER VALLEY: THE BEST METHODS FOR THE IMPROVEMENT OF THE SANITATION OF THE RIVER.

DR. R. W. GREENLEAF read a paper on

THE CHARLES RIVER IN ITS RELATION TO THE ETIOLOGY OF INTERMITTENT FEVER.¹

DR. H. C. ERNST: By common consent, we must consider the cause of most malarial diseases is a micro-organism. My experience with the subject under discussion is derived mostly from cases seen at the Massachusetts General Hospital, most of which came from Newton and regions about there already shown this evening on the map, and described in Dr. Townsend's report.

A plasmodium is not a form of bacterium; its existence in the blood has only been discovered a few years, and it has no relation to the bacterial forms of micro-organisms. They require special study, by new methods yet to be worked out. In many instances it is impossible to make a diagnosis between typhoid fever and malaria except by means of the microscope, which may reveal with proper preparation the hæmatozoon of malaria.

In order to make this examination, a bottle containing equal parts of alcohol and ether, and cover-glasses should be taken to the bedside of the patient; the cover-glass is to be carefully cleansed, a slight puncture of the patient's finger is made with a fine needle until a small drop of blood can be squeezed out, a thin layer of blood is spread over the cover-glass and carefully dried; then the glass is placed in the bottle containing the alcohol and ether, and kept until time for examination. To examine the specimen, it must be doubly stained by first immersing in a saturated solution of eosin in alcohol, or placing a few drops of the same on the cover-glass and allowing it to remain for ten to fifteen seconds; it is then washed off with water and treated with a saturated alcoholic solution of methyl-blue, when it is finally washed, dried and mounted. By this means the red corpuscle is stained red and the plasmodium blue. Under the microscope, it is found to be an amœboid form with dark pigment spots in the centre, which divides, and just before complete division assumes a seven-petalled, daisy-like form.

Dr. Ernst exhibited under the microscope the plasmodium of malaria.

DR. STEVENS said he could endorse the observations of Dr. Greenleaf. Most of the cases he had seen were a long way from the river, near fresh-water

brooks, old water-courses which were now drained or filled up, and standing water (as the old reservoirs in Cambridge and on College Hill, Somerville, and especially in Arlington). Before 1886 he had seen very few cases of intermittent fever in Cambridge; then it rapidly increased; but during the last five years it had greatly fallen off, so that at present there was not over one-quarter of the cases that formerly existed.

DR. DURGIN, in discussing the question of improvement of the sanitation of the river, said that official attempts had been made to remove the drains which emptied into the river from the Boston side along Beacon Street, and that these attempts had succeeded in part. The sewerage from the abattoirs of Brighton was no longer poured into the river. Some drains along Beacon Street were under discussion, and action was delayed in their removal to prevent unnecessary expense on the part of the land-owners in case the property behind their houses on the river bank should be taken by the Park Commission for improvements on the river.

DR. H. J. BARNES said he was glad to hear that Boston had done so well toward improving the sanitary condition of the river. Last year 80 drains emptied into Stony Brook, and thence into the Charles River. It was not long ago that he looked into the brook and saw a great amount of fecal matter floating about, which made him think of the conditions at Moon Island as he found them last summer.

During every great rainfall the flood-gates are opened into the Charles; the idea is maintained that by this means a large quantity of water is forced through the sewers, which are thereby flushed clear of their contents and maintained in a good condition. This is an erroneous conception, since except, perhaps, in times of drought, the ordinary circulation in the sewers is sufficient to keep them clear; and as their discharge into the river causes the accumulation of a great quantity of slimy, dirty material about the mouth of the drains which at times is very offensive, they should be done away with. He would not like to live in his house on Beacon Street in the summertime from this cause alone. What he had said about the mouths of the flood-gates was equally true of the condition of Stony Brook outlet in the Charles. Some people had informed him the smell about the place was simply that of dock odor, and not injurious to the health; but obviously it was a product of decomposing organic matter, and undoubtedly it was the reason that the organisms so useful in purifying the river no longer existed. At one time there was an extensive bed of oysters in the river, but they could not live where the sewerage rendered water so impure; and he had made the same observations at Moon Island, the shell-fish about the gateway having all died out.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.

JOHN C. MUNRO, M.D., SECRETARY.

REGULAR Meeting, Monday, February 5, 1894, DR. INGALLS in the chair.

CANCER OF THE CERVIX. — PATHOLOGICAL SPECIMENS.

DR. SWIFT: I thought this specimen would be of interest as it shows a number of pathological condi-

¹ See page 363 of the Journal.

tions occurring in one patient. It is a case of cancer of the cervix, in which there is also a fibroid on the anterior wall of the womb. On the right side there was a tubo-ovarian cyst, and on the left a hydro-salpinx. The case was also interesting as showing how easily in these pelvic troubles a wrong diagnosis may be made. This patient was first seen a year ago by a gynecologist in this city, the complaint being back-ache. It was found that she had an epithelioma of the cervix. He evidently felt this fibrous nodule and these tumors in the sides of the pelvis, for he told her that she had cancer of the uterus, and that the disease had extended so far that she could not be cured, but benefit would be derived from operation, and he was willing to undertake the operation of hysterectomy. She consented, but her friends objected. As time went on she became worse, and was taken into the City Hospital. There the same diagnosis was made and a radical operation was refused. The cervix was curetted, but the symptoms (pain) continued. She was practically bedridden. She came to me at the dispensary a while ago, and demanded that something be done. She said that with the history no hospital in the city would take her in. They refused her on the ground of her having cancer, an incurable disease. I examined her and made the same diagnosis that had been made previously. She was anxious to have the operation performed. Under ether it was found that these masses on the side were movable, evidently not attached to the pelvic walls, and there was some hope of getting out the whole mass. The disease by this time had extended down onto the anterior wall of the vagina, and I began the operation by dissecting up the vagina and removing all the diseased tissue that I could. I opened the peritoneal cavity from below, and putting my finger in there, found this large cyst on the right side perfectly free, and a smaller cyst on the left side, also free. On opening the abdomen these things came out without any difficulty at all, and if the operation had been done a year ago, probably her chance of ultimate recovery would be much greater than it is now. The operation was done last Friday, and the woman to-day is in very good condition.

DR. C. M. GREEN read a paper entitled

FOUR UNUSUAL CASES: I. IMPERFORATE HYMEN WITH HÆMATOCOLPOS; II. MUCOUS CYSTS OF THE VAGINA; III. RECTO-VULVAR FISTULA; IV. SALIVATION OF PREGNANCY.¹

DR. FORSTER: I was present with Dr. Green and saw the third case. It was a very interesting one and I took a sketch of it at the time which I think gives a pretty fair idea of the condition of the parts. It looked like a rupture of the perineum following labor, except that the vagina was entirely intact.

DR. WHITTIER: I was very glad to hear Dr. Green's paper on this form of reflex neurosis. I have never been able to understand why in the same individual it should be so constant in succeeding pregnancies when the chief of reflex neuroses, vomiting, is so inconstant and so variable. I have had three cases corresponding to the disorder described, and I think Dr. Green will remember I ventured last season to ask him with reference to the remedies that might be employed. The first case was seventeen years ago and in the succeeding pregnancy it was quite as un-

manageable. Four years ago a lady with her first pregnancy had among the earliest symptoms salivation, which continued during the whole period of pregnancy to an extreme degree, without the slightest sign of reflex disturbance in any other direction, and continued several weeks after the completion of pregnancy. I was of the opinion at that time that the continuance after the birth of the child was coincident with and dependent upon sub-involution of the uterus, which was present to a notable degree in that case. In the succeeding pregnancy, the earliest symptom of pregnancy preceding even the absence of the menstrual period, was salivation. This continued during the whole of pregnancy and lasted seven weeks after the completion of it. A lady consulted me last week who for five successive pregnancies, none of them completed, had as the first intimation, salivation. I need not say that we shall all accept Dr. Green's statement that this condition is, so far as remedies are concerned, quite unmanageable. I doubt if we may, with any degree of hope, expect to apply to this any remedy, such as those employed in the other so-called reflex neuroses of pregnancy, with fair success, for from all that I can learn of this disorder, it more nearly than any other deserves the title, incoercible.

DR. WASHBURN: I have been very much interested in this series of cases. In regard to the last one, I have now under my care a patient who has been troubled very much with salivation, and in that case there was an excessive amount of nausea and vomiting accompanying the salivation. The salivation was not as excessive as in some of the cases Dr. Green has spoken of, but it was constant and extremely annoying, and would amount to from a pint to a quart in the course of twenty-four hours. I tried a series of different things to see if anything would have any effect. Nothing had much effect, but I thought what gave the most relief was a combination of bromide of sodium with the effervescent bromo-cafeine, given in doses of ten grains of the bromide of sodium dissolved in water, to which afterwards a teaspoonful of the effervescent bromo-cafein was added. In that way it seemed to agree with the stomach perfectly, and it gave a little relief to the salivation.

In regard to the cases of cyst of the vagina, I saw a case about two years ago, that showed the possibility of error in another direction. A woman came to me with a small enlargement on the anterior wall of the vagina, about the junction of the outer and middle thirds, which apparently was a vaginal cyst. Examination, however, showed that the contents of it could apparently be squeezed out, and I found that a fine probe passed into the urethra could be gotten to enter this little sac. It would often be quite distended with the urine and a little *débris* that collected there. It gave her a great deal of discomfort in various ways and I finally opened it and denuded the surface, and sewed up the little fistula into the urethra, and the thing healed very well, and she has been perfectly comfortable ever since. But the first examination of that gave every appearance of being a vaginal cyst. A vaginal cyst which I saw recently was situated almost at the vaginal outlet, and the size of an English walnut. In three or four cases I have seen, the cyst has been along about the middle third of the vagina. I think that the way to reach these always is by the operative method, and my experience has been that of Dr. Green, that very often you cannot find any cyst

¹ See page 356 of the Journal.

fall to dissect out. You simply have to lay it open and take off a piece of the outside, scrape it out and let it granulate up in that way.

DR. BUCKINGHAM: I have met with one case of salivation in pregnancy, and like those of Dr. Green and Dr. Whittier, it had appeared in a former pregnancy as well. It was so severe that the patient spent her whole time on the bed, with her head over the edge, and her mouth draining into a basin. She was much emaciated and the condition would have been alarming but for her assurance that she had suffered even more in her former pregnancy. Each time salivation ceased about the fifth month. She was treated with a number of drugs commonly used for the neuroses of pregnancy, the only one doing any good being atropia. I do not believe that that hastened recovery, but it gave considerable temporary relief, and it could be repeated.

Recent Literature.

A Text-Book of the Theory and Practice of Medicine. By American Teachers. Edited by WILLIAM PEPPER, M.D., LL.D., etc. In Two Volumes. Illustrated. Vol. II. Philadelphia: W. B. Saunders. 1894.

The second volume of this important work makes its appearance somewhat later than had been anticipated. It is a year since the publication of the first volume. In a certain measure this is compensated for by the incorporation of the latest investigations and studies in some subjects. The first 69 pages are devoted to general considerations concerning the biology of bacteria, infection and immunity, by Dr. W. H. Welch. It is interesting to compare this contribution with those from the same pen on kindred subjects in the last edition of Flint's "Practice of Medicine," published in 1886. One may thus get a striking illustration of the activity and advance of research in this department of medical science during the short space of eight years. Dr. William Pepper contributes 325 pages out of the 1,000 pages of text contained in the volume, and writes on diseases of the heart and its membranes, of the blood-vessels, of the mediastinum, of the mouth and tongue, the salivary glands, the pharynx and tonsils, of the esophagus, the stomach and the intestines. Dr. R. H. Fitz treats of diseases of the peritoneum, the liver and the pancreas. Dr. Francis Delafield has considered diseases of the lungs and of the kidneys; Dr. James C. Wilson, diseases of the nose, larynx, pleura and bronchi; Dr. William Osler, diseases of the blood, of the supra-renal capsules and ductless glands; Dr. James W. Holland contributes a chapter on practical urinary examination; and Dr. Henry M. Lyman chapters on dietetic diseases, the acid dyscrasia, rickets, osteomalacia, obesity, biliary lithiasis, gravel, saccharine diabetes, polyuria, rheumatoid arthritis, gout and rheumatism.

The title-page states succinctly the plan upon which the work is made up; the names of authors embrace a number of the prominent teachers of clinical and theoretical medicine in the chief medical schools of this country, and may be held in a measure as a guarantee of the character of the work.

The paper, the letter-press, and most of the illustrations, which are numerous—are first-rate. Each volume has a separate and full index.

Holden's Manual of the Dissection of the Human Body. Edited by JOHN LANGTON, Surgeon to, and Lecturer on Anatomy at, St. Bartholomew's Hospital, etc. Sixth edition, revised by A. HEWSON, M. D., Demonstrator of Anatomy at Jefferson Medical College, etc. 311 illustrations. Philadelphia: P. Blakiston, Son & Co. 1894.

This new edition of a well-known work calls for no very extended comment. The bulk has been reduced by putting the more minute points in smaller type. The binding is more simple and well adapted to the dissecting-room. There is a great deal in this work that explains its continued success. For our part we think it would have been wise to omit all minute anatomy. The dissector can have nothing to do, for instance, with the plan of the renal tubules, nor the blood-vessels of an intestinal villus. All this is out of place, if the book is intended to be merely a manual of dissection. We are least pleased with the treatment of the abdominal viscera, and would particularly protest against the implication that the back of the cæcum is often or usually destitute of peritoneum. T. D.

Healthy Hospitals: Observations on Some Points connected with Hospital Construction. By SIR DOUGLAS GALTON. With illustrations. Oxford: Clarendon Press. 1893.

The author's object in writing this book was to place on record those principles which ought invariably to be followed in every good hospital, and to point out those conditions of construction which according to recent practice represent the minimum standard required to be followed in building a new hospital. The author does not enter upon the detailed requirements of hospitals for special diseases, entailing in some cases separation of patients, in others special curative adjuncts. He recognizes the probability that a large number of new hospitals for infectious and other diseases will have to be built in the next few years, and endeavors to impress the importance of simplicity of design and moderation in cost. The book is one which those interested in hospital construction should consult.

The Physician's Wife; and the Things that Pertain to Her Life. By ELLEN M. FIREBAUGH. With portrait of author and 44 photo-engravings of original sketches. In one crown octavo volume of 200 pages. Philadelphia: F. A. Davis Co. 1893.

Mrs. Firebaugh has expanded what was probably a very interesting paper, as read to a club, into the proportion and dignity of a book.

It is difficult to believe that the author is really the wife of a physician, so much has been omitted that could have been said in regard to the peculiar duties, hardships and rewards of the life of a doctor's wife, and so many anecdotes contained in the 186 pages could have been related as well of the wife of a banker or a grocer. For instance, it is not clear why the fact of being a physician's wife should cause the lady in question to insist that cabbages should not grow in her front-yard, or why her husband, because he is a physician, should be equally determined that they should.

For a busy doctor's young wife, who is beginning to learn that her husband's time, and, it often seems, his interests also, must belong to his patients rather than his home, there is little to aid or comfort; while to the wife of many years much in the book will appear trivial and commonplace.

BROWN-SÉQUARD'S TEACHING.

IN the recent death of Brown-Séguar — so well known personally to many of the readers of the JOURNAL as having been a citizen, practitioner and medical teacher for several years in this city, and a frequent visitor to this country — the world has lost the last of a distinguished band of experimental physiologists, with all of whom he had been contemporary, and who have helped to make this century fruitful in scientific discovery. The mere mention of the names of the most conspicuous in this band — Flourens, Magendie, Claude Bernard, Vulpian, Longet, Charcot — recalls some of the most valuable acquisitions in neuro-physiology of the past sixty years.

We shall not repeat the facts in Brown-Séguar's medical career mentioned in the JOURNAL of last week. His memoirs on the physiology of the nervous system in both French and English (he wrote with equal facility in both languages) are very numerous. He is best known in this country by his work "On Paralysis of the Lower Extremities," his "Experimental Researches applied to Physiology and Pathology" (New York, 1858), and his "Lectures on the Physiology and Pathology of the Central Nervous System," first delivered in London in 1858, and published in this country in 1860. This is an "epoch-making" book, and sums up his most important investigations on the spinal cord. In 1856, he delivered a course of lectures in Boston, on "The Pathology of Epilepsy," which attracted much attention; these were published in the JOURNAL in 1856 and 1857.

Probably of all his works, that on the "Physiology and Pathology of the Nervous System" has been the most read, and we well remember the eagerness with which it was sought for and read by students of medicine at the time of its publication, thirty-odd years ago.

It is impossible to overestimate the advantage which has accrued to science from these researches, so replete with originality, on perhaps the most difficult part of nervous physiology. We may point particularly to the

anatomical and experimental facts set forth in those lectures, showing the relative share of the gray matter and of the various columns of white matter in the transmission of both sensory and motor impressions, and to the demonstrations there given: (1) That the conductors of sensory impressions from the trunk and limbs decussate in the cord and not in the encephalon [Brown-Séguar, by the way, subsequently took this all back, and affirmed that the decussation does not exist¹]; (2) that in the dorsal region, the various parts of the cord except the posterior columns are instruments of volition; (3) that a small part of the cord may contain conducting elements from all parts of the body on the same side; (4) that the anterior columns have a share in the transmission of sensory and, particularly, tactile impressions; (5) that in cases where the gray matter is destroyed, sensibility is lost; (6) that the fibres of the sympathetic going to the blood-vessels of the head originate in the spinal cord from the roots of the last cervical and first and second dorsal nerves, etc. Brown-Séguar's investigations of the vaso-motor and cervical sympathetic nerves, and his doctrine on the "Transfer of Sensibility" are of the highest interest. With regard to the vaso-motor nerves, following Claude Bernard, he established that the effects of excitation of these nerves consist essentially in a contraction of blood-vessels with diminution in the blood flow, in the temperature, and in the activity of nutrition. He was the first to galvanize the sympathetic nerve. He showed, also, that irritation of the nervous system is a powerful direct or reflex cause of a great many morbid changes in nutrition, secretion, etc.

Brown-Séguar was the first artificially to produce epilepsy in animals by injuries to the spinal cord in certain regions, and to demonstrate the existence of an "epileptogenous zone" in guinea-pigs. His views as to the pathogeny of epilepsy are of the highest interest, though they have been in many points contested. Thus the "contraction of the blood-vessels of the brain proper," precursor of the loss of consciousness, was disputed, if not disproved by Vulpian, and the weight of authority to-day is against the view that the primary seat of epilepsy is in the medulla oblongata instead of in the cortex cerebri.

Dr. Brown-Séguar followed the teachings of Flourens respecting the functions of the cerebrum. According to Flourens, all the properties of the cerebrum are inherent in every part, and from this standpoint he made vehement war on the localizationists of the time, the phrenologists. Brown-Séguar was never willing to accept the modern views of localization, as they were expounded by Ferrier, Nothnagel, Charcot, Seguin and others; in fact, he always bitterly opposed these notions of cerebral physiology; and he has been cited as a striking example of the baneful influence of a strong prepossession or bias. As Agassiz could never see any force in the arguments of the evolutionists, so, to Brown-Séguar, Ferrier's experiments on monkeys

¹ London Lancet, August, 1880 (Am. Ed.), p. 188.

were only illustrations of reflex inhibitory action, not of direct irritation or of destruction of well-defined centres. He had accumulated facts which led him to believe that paralysis, anæsthesia, amaurosis, aphasia, and other effects of brain-disease are not dependent on loss of function of either the centres or conductors specially employed in voluntary movements, perception of sensations, power of expression of ideas by speech, etc. He taught that a lesion of any part of the brain may produce any symptom, and that, on the other hand the same symptom may appear, no matter where the seat of lesion may be. A lesion in any part of the brain can produce paralysis, either on the same side or on the opposite side of the body. A paralysis may appear on one side, then on the other side, although the lesion remains in one-half of the brain. As regards vision, facts, according to Brown-Séquard, show that a disease in one-half of the brain can produce hemiopia either in both eyes or one, and in the corresponding or the opposite halves of the retina, or a complete amaurosis of either of the two eyes or of both together, so also, anæsthesia, aphasia, loss of consciousness, etc., may arise from lesions in almost any part of the brain. One of the doctrines that he stoutly maintained was this, that the seat of each special function of the brain, instead of being a cluster of cells localized in a small part of the brain, is disseminated, so that the cells belonging to each are spread over a considerable extent, if not the whole extent of the brain.²

We have not space here to comment on these views; the work has been done by Charcot, Seguin, Foster, Soury, Luciani, Ferrier and others. It is enough to say that Brown-Séquard had a comparatively small following; that his peculiar teachings in which he combated with acerbity the views of his opponents were always listened to with respect and patience, but with incredulity by medical audiences; and that the physiology of to-day is moving farther and farther away from his positions. Brown-Séquard will always deserve a large place in the annals of medicine for the many facts with which he has enriched science, but, like Magendie, he was not a philosophic thinker, and though a good observer, he did not always correctly interpret the facts which he observed.

THE INTERNATIONAL MEDICAL CONGRESS.

THE Twelfth International Medical Congress came to a brilliant close on April 5th, and there seems to be little doubt that as regards the friendly relations of all the members and the generous hospitality of the entertainers, it has been the most successful meeting yet held.

The Congress was formally opened on Thursday, March 29th, in the presence of the King and Queen of Italy and the officers of the Court. Professor Baccelli delivered his inaugural address in Latin to an audience of six thousand persons. Prince Ruspoli,

the Syndic of Rome, extended to the members the welcome and hospitality of the city.

The immediate glory of the meeting; the dinners given by the foreign ambassadors to the officers of the various sections; the splendid lawn party given by the Queen to the whole Congress; the many private entertainments and public hospitalities of open gallery and museum; and the final banquet in the great court of the Baths of Caracalla when seven thousand persons were gathered together in the vast dismantled ruins of that unequalled athletic club of Imperial Rome, — all these, brilliant as they might be, were but rich appointments of the true feast.

Of the actual work of the Congress; its nineteen sections, each sitting for five days from 8 A. M. to 8 P. M.; its sixty-nine pages of titles of papers to be read; its five general meetings to listen to addresses by Babes, Bizzozero, Bouchard, Danilewski, Michael Foster, Abram Jacobi, Laache, Nothnagel, Stokvis, and Virchow, — it is too soon to speak. The value of such addresses and such extensive sectional work can only be appreciated after they have become widely known, thoroughly read and studied in full. Brief epitomes of such papers are apt to give, not merely unsatisfactory, but often false impressions of the statements, the arguments, the conclusions therein contained. On the arrival of our carrier pigeons, a thousand of which were set free at the close of the final banquet in the Thermæ, we may give our readers even more details than could have been sent by special cable. The list of speakers and papers was a most promising one for the real worth of the Congress.

MEDICAL NOTES.

A LONG MEDICAL LIFE. — Dr. Schupmann, who died recently in Geseke in Westphalia, was probably the oldest physician in Germany. During the first fifty years he was in practice it is stated that he never left his district for a single night, and he did not finally retire from active practice and the charge of the local hospital until he was past ninety years of age.

DANGER FROM HEATED CABS. — The introduction of heating apparatus in some of the public carriages of this city, while of great comfort to the rider, makes worthy of note the following cases reported to the Académie de Médecine of Paris, by M. Dr. Brouardel: "On the 31st of last December a cab-driver who went to sleep in his cab for half an hour after closing the windows was found dead, and the autopsy showed that the death was due to poisoning by carbonic oxide gas from the heating apparatus. On the same day a physician, after an hour's consultation, entered his heated carriage without noticing that the windows were closed. In a few minutes he became dizzy, nauseated, and was seized with such muscular weakness that he could scarcely lower the window. The serious effects of this brief exposure to the gas lasted some ten days." In the discussion following this report it was stated

² See Brown-Séquard's lecture in the *Lancet*, April 5, 1876, and the *Lancet's* comment on the lecture.

that from five to eight deaths are reported every winter in Paris from gas-poisoning in heated cabs. Another physician since then has nearly lost his life in a similar manner, being found by the driver, unconscious on the seat.

MEDICAL CHARITIES OF LONDON.—The present discussion in English medical journals on hospital and dispensary abuse can be better appreciated after realizing the large number of institutions of direct medical charity. The *Directory of Metropolitan Charities* gives the following list of hospitals and dispensaries in London, not including foundling asylums or diet-kitchens: "Twenty-five charities for the blind, seven charities for deaf and dumb, five charities for incurables, two charities for idiots, sixteen general hospitals, eight consumption hospitals, five ophthalmic hospitals, three orthopedic hospitals, five skin hospitals, sixteen hospitals for women and children, four lying-in hospitals, twenty-nine miscellaneous special hospitals, twenty-nine general dispensaries, thirteen provident dispensaries, six institutions for surgical appliances, twenty-six convalescent institutions, seven nursing institutions." They number 206 in all.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—During the week ending at noon April 11, 1894, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 42, scarlet fever 45, measles 9, typhoid fever 10, small-pox 3 (with 3 deaths). There are at present ten cases in the Small-Pox Hospital. During the week one case of small-pox was reported to the State Board of Health from Chicopee.

THE MASSACHUSETTS HOMŒOPATHIC MEDICAL SOCIETY.—The programme of the annual meeting of the Massachusetts Homœopathic Medical Society included a luncheon at the State Insane Hospital at Westborough.

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF PHYSICAL EDUCATION.—The ninth annual convention of the American Association for the Advancement of Physical Education was held last week in New Haven, Conn., with an attendance of nearly four hundred delegates.

A SUIT FOR DAMAGES IN A CASE OF SMALL-POX.—A suit for \$15,000 damages has been brought against the Selectmen of Ansonia, Conn., by the father of a boy who was taken to the small-pox hospital of that town by order of the selectmen in 1892. The boy died of the small-pox, and the father claims that the removal was the cause of death.

NEW ENGLAND ALMSHOUSES.—The Boston Almshouse is not the only one at present under investigation as to the methods employed to give the inmates the full benefit of money appropriated for their care. The Portland, Me., city government has been asked to investigate the almshouse, and to restrain the board of overseers of the poor from holding their regular

monthly dinners at the almshouse at the cost of the city.

A CASE OF CATALEPSY IN LOWELL.—A woman was found apparently dead in Lowell last week; and on the arrival of the ambulance gave none of the ordinary symptoms of life when examined by the surgeon. Just as the ambulance drove up to the undertaker's establishment, the surgeon noted a flicker of the eyelids, and the patient was carried, still insensible, to St. John's Hospital, where after several hours' treatment she rallied from her cataleptic state.

TOWN CLERKS AND MEDICAL ORTHOGRAPHY.—Massachusetts town clerks have a fearful struggle with the nomenclature of disease as presented to them in the certificates of death returned to them by physicians. The following are some of the diseases of which citizens of this commonwealth were said to have died in the year of our Lord 1893, taken *verbatim et literatim* from town reports: In Wellesley—taber dorsalis, extensive bronis, acute ayetitis, asphyxia neonatonim, gastirentiritis, chronic parenchymatoes; in Milford—sewicility (aged seventy-two), nutral disease of the heart, gastertis, caranomia, suppressaricella [Query, Was this Ayer's Sarsaparilla?].

REPORT OF THE PERKINS INSTITUTE.—The sixty-second annual report of the trustees of the Perkins Institution for the Blind shows a continued increase in the number of pupils and in amount of work done at the school and kindergarten. There are now one hundred and forty pupils in the school proper at South Boston and sixty-four in the Kindergarten at Jamaica Plain and seventeen in the workshop for adults. The director's report says that the progress of the three blind and deaf children, Edith Thomas, Willie Robin and Tommy Stringer, has been more than satisfactory. They have been placed in the regular classes and subjected to the same rules as others, the only difference being the presence of their special teacher as interpreter. Their progress compares favorably with that of their classmates, and doubt can no longer be entertained of the feasibility of educating children thus deprived. The number of these is sufficient to make it a duty to seriously consider the means of their education. The schools for the deaf generally have no provision for the blind child, or the schools for the blind for a deaf pupil.

NEW YORK.

TUBERCULOUS CATTLE DISCHARGED BY THE STATE BOARD OF HEALTH FOR LACK OF FUNDS TO INSPECT THEM.—It is greatly to be regretted that the present Legislature has neglected to make a suitable appropriation for the further carrying out of the act passed last year, which conferred extraordinary powers on the State Board of Health for the purpose of stamping out tuberculosis and other contagious diseases among cattle. For some time past the Board has been seriously crippled for lack of funds, and last month, when it was notified of the existence of tuberculosis in the cows of Colonel

Beecher, at Yonkers, whose grandchild died of tubercular meningitis, the Secretary of the Board, Dr. Balch, wrote in reply that it would be impossible for the State officials to make an examination of the animals mentioned for some months at least. "This department," he said, "is working under a very small appropriation for tuberculosis, and unless the present Legislature makes an additional appropriation, it will take us several months to attend to the requests already on file." And now, under date of April 6th, the Board has issued an order directing the release of cattle suffering from tuberculosis and the discharge of cattle inspectors, because of the insufficiency of the funds at its disposal. This order has naturally caused great indignation among cattle-owners, many of whom have sacrificed some of their most valuable stock for the purpose of exterminating the disease, and it is feared that the most serious consequences will ensue. A large number of tuberculous animals have been quarantined awaiting slaughter, and the order to release them permits their sale and distribution throughout the State and the country at large.

A COMMISSION TO INVESTIGATE TENEMENT-HOUSES.—The Legislature has passed a bill which provides for a committee of seven citizens, including Dr. Cyrus Edson, Commissioner of the Board of Health, for the purpose of investigating the condition of tenement-houses in New York. The commission is authorized to employ counsel and a stenographer, and to compel the attendance of witnesses, and \$10,000 is appropriated for its expenses.

Miscellany.

THE USE OF ANTIPYRETIC METHODS IN THE TREATMENT OF SCARLATINA.

DR. JOHN CARSLAW, of Glasgow, in a paper on "The severer forms of scarlet fever, with special reference to antipyretic methods of treatment,"¹ based on the study of six hundred and thirty cases, draws the following conclusions in regard to the external use of applications of cold and tepid water:

(1) That, in the large majority of cases, they are not required.

(2) That, even in simple cases, and in anginous cases, tepid spongings are useful in allaying restlessness and giving comfort — if the rash has not developed, the addition of mustard being an advantage.

(3) That mustard spongings are particularly useful during the earlier stages of an attack in which nervous phenomena are prominent.

(4) That for the hyperpyrexia of such (nervous) attacks, especially if the rash has developed, repeated cold wet packing is a convenient and efficacious method of treatment, general improvement often following its use.

(5) That local applications to the head may sometimes be of assistance.

(6) That, in all cold applications, there is need for the exercise of the greatest care.

¹ Glasgow Medical Journal, Nos. I and II, 1894.

THE INTERNATIONAL SANITARY CONFERENCE.

THE closing session of the International Sanitary Conference at Paris was held on April 4th, and an international convention was signed by all the delegates, those from the United States and Great Britain making reservations in regard to a few details.

The measures deal with three aspects of the cholera question, and are reported to be minute in their requirements. The first series provides for a thorough inspection and control over the embarkment of all pilgrims from Indian ports for Mecca, and for proper medical service on all vessels carrying pilgrims. The second series provides for the reorganization of the Turkish lazarettos on the Red Sea. The quarantine of pilgrim ships from India, formerly varied from two to seven weeks, whether the vessel had a clean bill of health or not. By the terms of the new convention a ship with a clean bill of health will be delayed only long enough for medical inspection, and contaminated or suspected vessels will not be detained in quarantine more than five days. The third series relates to precautionary measures in the matter of the return of pilgrims from Mecca by the lazaretto of Tor in Arabia Petrea, on the east shore of the Gulf of Suez. The conference has earnestly urged the Turkish Government to reorganize its sanitary administration thoroughly, with the view of preventing the introduction of cholera into Europe by land. With what result?

THE TREATMENT OF CHRONIC RINGWORM OF THE SCALP.

IN the Dermatological Section of the British Medical Association, held at Newcastle-on-Tyne, August 2, 1893, the above subject was introduced by Dr. Calcott Fox, and discussed by various members. Dr. Fox, in considering the parasiticide treatment, asked whether it was possible to make strong parasiticides penetrate the hair follicle and to bring them into contact with the diseased root and thus to destroy the parasite, as has been denied by Besnier. He was not wholly prepared to accept the latter's view, but yet regarded purely parasiticide treatment as a slow means of cure. Irritative treatment was commended as effective, but would be more advisable if the desired amount of irritation could be produced at will. He also recommends shaving. Treatment by croton oil in obstinate cases had yielded the speaker brilliant results, but it should always be kept in the hands of the physician.

Some of the speakers who followed favored the use of strong irritants and croton oil, others did not. Dr. Alder-Smith declared that in 90 out of every 100 cases that he had really cured, he had had to employ some croton oil sooner or later, or had had to needle out some isolated stumps left after other remedies had failed. Dr. Radcliffe Crocker considered croton oil a valuable remedy, most useful in very disseminated cases, but one which must be very carefully employed. He recommended oleate of copper, and for older children, salicylic collodion. Dr. Brooke uses as a base a modified Lassar's paste, with kaolin substituted for oxide of zinc, so as to make the preparation more sticky; he adds to this sulphur or creolin as a parasiticide. He was doubtful as to the value of epilation, and considered the croton oil treatment admissible only when the patient could be seen daily by the physician. Dr.

Thin considered it necessary for the cure of ringworm to set up an inflammation about the hair follicle sufficient to kill the parasite; but this inflammation must be carefully controlled, as he had seen cases where large areas of permanent baldness had been produced by croton oil. He did not favor therefore the use of croton oil, except in very exceptional cases, and in very exceptional hands. He had found that ringworm hairs that had been soaked in croton oil for a week, still caused a growth of the fungus in cultivating media, and therefore its effect must be due to its irritating and not to its parasitocidal properties.

A FAMOUS COUNTRY OBSTETRICIAN TWO CENTURIES AGO.

In the second volume of the "Philadelphia Hospital Reports," recently published, Dr. Theophilus Parvin contributes a sketch of the work of Manquest de La Motte, a famous French obstetrician of the last half of the seventeenth century. Although he was educated in medicine at the Hôtel-Dieu in Paris, he returned to the small country town of Valognes in Picardy to practise. Leading the busy and arduous life of a country doctor, he gradually acquired fame as an obstetrician "by adding reading to practice, observations to reading, and reflections to observations."

In 1726, when he was seventy-one years old, he published his "*Traité des Accouchements*," making this modest claim for its merits: "I have waited a longer time to publish this work, hoping to make greater progress; but my advanced age has decided me to issue it as it is, fearing that unforeseen death may deprive me of the pleasure of giving some light to my successors, trusting that the Lord will reward, not living in a place in which fortune can fulfil the desires of those who sacrifice to this idol."

What was the variety of work done by this physician, who frequently rode twenty or thirty miles on horseback to attend a case of labor, is exemplified by the reports of over 400 cases, written in a most interesting and vivid manner. The following passages will meet the ready appreciation of the tired doctor of to-day:

"Mother and child saved, but I almost died; and I was so fatigued and exhausted I could not use my legs and arms for eight days. . . . I believe I would have died when this accouchement, in which I had exhausted my knowledge and my strength, ended. I could scarcely breathe, and it was necessary to put me upon a mattress in front of the fire and to rub me with warm cloths. . . ." Of the closing moments of a labor he says, "The child escaped from the vulva as readily as an eel slips through your hand." So great was his regard for the feelings of his patient in conducting a labor, that it was said that "he would not so much as see the patient's feet when her slippers were off."

He was a master in podalic version, which was his favorite and chief obstetrical operation; and he asserted that, in obstructed labors, "in any other presentation than that of the head, the Lord had given him the means of extracting living children if he were called in time." The forceps devised by Palfyn he had heard of, but condemned, as he said he did not see "how an instrument of steel or other material could be passed to the place where the head is arrested and

wedged, usually in the strait formed by the ischia, the sacrum and the pubis, so closely that a sound to evacuate the urine which has been retained for several days cannot be introduced, nor a canula for rectal injection, not even a myrtle leaf; how can such an instrument be applied and used to remove the infant from the peril to which the narrowing of the parts exposes it? . . . Its use would be as impossible as to pass a cable through a needle's eye."

He was one of the first to recognize the narrowed pelvis as a cause of dystochia. Throughout his book are related unusual and interesting cases; one woman dying of fright consequent on his attendance; one woman who had thirty-two children before she was forty-five, when she lost her husband. Patience and refraining from meddlesome midwifery were the chief characteristics of his work. His self-independence and practical opinions he recorded in these words:

"As I have lived at the extremity of a province surrounded on almost all sides by the sea, and have worked most frequently in the depth of a country without physicians or surgeons who could aid me by their counsels, I have been compelled to conduct my practice most frequently in seeking to aid nature and to calm the accidents of pregnancy and labor, so far as common-sense and my reflection have furnished the means, without too great subjection to authorities and making myself a slave to common usages, at least when I did not know the necessity for conforming to them in reference to the disease, the constitution of patients and other circumstances from which practical considerations can be drawn."

THE NECESSITY FOR A WELL-PAID MEDICAL PROFESSION.

In an address before the Southwest London Medical Society Mr. Thomas Bryant urged the importance of physicians being well paid for their services.¹ He said:

"Let us never forget that our patients' interests are those we should always primarily consider, and that in all our practical and scientific professional work the public good is its ultimate object; but at the same time let us bear in mind that in order to realize this leading purpose it is all important for the interests of the public, as well as for the due exercise and dignity of our profession, that every practitioner of medicine should hold a perfectly independent but responsible position, and that in his professional work he should be left perfectly free from lay control, although amenable to lay censure. It is also equally necessary that he should be adequately paid for his professional services by all classes according to their means. Under these circumstances all measures, whether under the guise of charity or called 'provident,' and all hospitals, general, special, or private, which encourage the public to seek professional advice for little or nothing, are to be discouraged as helping to pauperize and degrade the public at large; and all members of our profession who induce or tempt the public so to do by means of private hospitals, competing private dispensaries, touting clubs and associations, or who are ready to accept at a reduced figure, over the heads of their neighbors, appointments which have been put up by laymen, as it were, to auction or competition, adopt the surest means with-

¹ *Lancet*, February 10, 1894.

in their power to lower the position of their profession in the estimation of the public, and at the same time do injustice to the profession and public by not giving to the latter the best services the former can supply, whilst they must, in addition, lose their own self-respect, even if they happen to gain cash by their unworthy actions. For let me ask, How is it possible for a man who is ill-paid or overworked, or both, either to give, in the interests of the public, the professional attention it is essential for him to bestow on every case he has undertaken to attend; or to maintain, in the interests of the profession, the position to which he is entitled and his own self-respect? We all know that any measure which encourages, either in a profession or trade, underpay and overwork, leads to bad work. In our profession such deficiencies are no less harmful—nay, they are more so, as its issues to the public are either life or death, health or ill-health, and to the profession either a position of pleasure, honor and respect, or one of degradation and unrequited labor."

CROTALUS HORRIDUS.

THE following description of the initial steps in the securing and preparing of the "mother tincture of *Crotalus Horridus*" receives the sanction of two homœopathic medical journals. A box of twenty-four large rattlesnakes was received by a museum proprietor in Rochester. Having provided a long hempencord, a bottle of ammonia and some whiskey, "to be prepared for an emergency," the owner, known as "Rattlesnake Pete," unfastened the lid of the box and, as a large snake darted out, seized it by the neck and carried it to a table, while the long lithe body coiled round his arm and the rattles were "singing away like grasshoppers."

Now comes the interesting part of the performance. A piece of common window-glass was placed near the snake's open mouth, and the rattler struck his wicked-looking fangs, which were nearly an inch in length, against the glass, a thin stream of yellowish looking liquid spurting upon it at each stroke. "Oh, he's full of it," said Pete. "There's poison enough right there to kill twenty men." While he spoke he walked toward the den, and giving the snake a quick twist, released him. The poison on the glass was absorbed with sugar of milk, scraped into a bottle and carefully sealed. The poison thus obtained is sent to certain London homœopathic physicians, who use it in their practice as a medicine for diphtheria and other diseases of a similar nature. The poison is supposed to be very valuable. The process just described was repeated with snake after snake, until all in the box were transferred to the den. After the first three or four were taken out, Pete plunged his hand among the mass of wrigglers with seeming impunity, dragging out his next victim with a quick but certain motion. "These fellows will give up their poison more readily to-morrow; they are a little sluggish on account of having been kept in such close quarters for the past forty-eight hours," said Pete, in response to the writer's query.

"Besides selling the poison, which I have told you about," added Pete, "when a snake dies, I try-out the fat of the reptile, and obtain from one and a half to two ounces of a very penetrating oil, from a fair-sized snake. This oil is worth eight dollars per ounce, and is used as a specific for deafness."

METEOROLOGICAL RECORD.

For the week ending March 31, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Deaths reported 2,502: under five years of age 936; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fever) 369, acute lung diseases 416, consumption 239, diphtheria and croup 157, scarlet fever 52, measles 37, diarrhoeal diseases 36, whooping-cough 26, typhoid fever 21, erysipelas 15, small-pox 8.

From measles New York 24, Brooklyn 7, Philadelphia and Milwaukee 2 each, Cleveland and Pittsburg 1 each. From whooping-cough New York 7, Brooklyn 6, Philadelphia 4, Cambridge 3, Cleveland and Pittsburg 2 each, Somerville 1. From typhoid fever Philadelphia 5, Boston and Pittsburg 3 each, New York, Cincinnati, Cleveland and Lowell 2 each, Springfield and Malden 1 each. From erysipelas New York 6, Brooklyn 5, Boston, Cleveland, Pittsburg and Pittsfield 1 each. From small-pox New York 4, Brooklyn 3, Boston 1.

In the thirty-three greater towns of England and Wales with an estimated population of 10,488,442, for the week ending March 24th, the death-rate was 19.8. Deaths reported 3,979: acute diseases of the respiratory organs (London) 347, measles 162, whooping-cough 123, diphtheria 84, scarlet fever 39, fever 38, diarrhoea 25, small-pox (Birmingham and Oldham 5 each, London 1) 11.

The death-rates ranged from 10.6 in Derby to 26.1 in Salford; Birmingham 21.0, Bradford 17.5, Cardiff 18.2, Hull 16.2, Leeds 18.9, Leicester 19.8, Liverpool 23.0, London 20.3, Manchester 23.8, Newcastle-on-Tyne 20.1, Nottingham 18.0, Portsmouth 13.1, Sheffield 17.4.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 31, 1894, TO APRIL 6, 1894.

CAPTAIN EDWARD C. CARTER, assistant surgeon, will proceed at once to Fort Spokane, Washington, and report to the commanding officer for temporary duty.

Leave of absence for twenty-one days, to take effect on or about April 14, 1894, is granted MAJOR CHARLES L. HEIZMANN, surgeon, U. S. A.

The following named officers are detailed to represent the Medical Department of the Army as delegates to the Association of Military Surgeons of the United States, to meet in Washington, May 1, 1894: LIEUT.-COL. WILLIAM H. FORWOOD, deputy surgeon-general; MAJOR ROBERT M. O'REILLY, MAJOR JOSEPH K. CORSON and MAJOR WALTER REED, surgeons; CAPTAIN JOHN L. PHILLIPS, CAPTAIN G. L. EDIE, assistant surgeons.

FIRST-LIEUT. HENRY D. SNYDER, assistant surgeon, is relieved from duty at Fort Reno, Oklahoma Territory, and ordered to Fort DuChesne, Utah, for duty at post, relieving CAPTAIN SAMUEL Q. ROBINSON, assistant surgeon.

CAPTAIN ROBINSON, on being relieved by FIRST-LIEUT. SNYDER, will report in person to the commanding officer, Davids Island, New York, for duty at that post.

MAJOR PETER J. A. CLEARY, surgeon, will be relieved from duty at Fort McPherson, Georgia, by the commanding officer of that post, on the receipt by him of this order, and will report in person to the commanding officer, Fort Custer, Montana, for duty at that post.

FIRST-LIEUT. EDWARD L. MUNSON, assistant surgeon, will proceed without delay to Camp Merritt, Montana, and report to the commanding officer, for temporary duty at that post.

FIRST-LIEUT. CHARLES F. KIEFFER, assistant surgeon, having reported at Hdqrs. Dept. Dakota, is assigned to temporary duty at St. Paul, Minn., and will report to the medical director of the department for instructions.

SOCIETY NOTICES.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT. — The Section for Clinical Medicine, Pathology and Hygiene will meet at 19 Boylston Place, on Wednesday, April 18th, at 8 o'clock.

Dr. E. G. Cutler will report "Two Unusual Cases of Malaria, one of Remittent Fever followed by Death, the other Successfully Treated." Dr. W. T. Councilman will show pathological specimens and Dr. A. P. Chadbourne will report on "The Clinical Use of Malacine."

F. C. SHATTUCK, M.D., *Chairman*.
HENRY JACKSON, M.D., *Secretary*.

AMERICAN MEDICAL ASSOCIATION.

SAN FRANCISCO MEETING.

The Committee of Arrangements for Transportation report that after strenuous endeavors to secure for members of the Association a round-trip ticket to San Francisco for the cost of a single full fare, they have so far succeeded that about one-half of the railroads have favored the committee's petition. These are chiefly the lines west of the Missouri, from which points thirty-day tickets can be had over various lines for but little more than a single fare. If arrangements can be made with Eastern railroads, over which there is more local travel, the entire journey can be made for a very low price.

The Committee desire a concerted effort of the members in the East to secure such reduction over lines east of the Missouri River.

AN EXCURSION TRAIN FROM CHICAGO.

Dr. Liston H. Montgomery, of Chicago, announces that arrangements have been made for a special train to leave Chicago on Tuesday, May 29th, at 10.30 P. M., arriving at Omaha, Wednesday noon, and Denver on Thursday morning at 7.30 of the 31st. Stop overs will be granted to visit any of the sanitary

or pleasure resorts throughout Colorado. At Denver there will be opportunity for a side excursion to any of the sanitariums or to Silver Plume over the Georgetown loop. From Denver the route is via Cheyenne, Ogden and Salt Lake City, where a stop over will be made to visit the Lake and Garfield Beach. From Utah the route is over the Southern Pacific and the train is due at San Francisco. The return will be made by the Shasta route.

BOOKS AND PAMPHLETS RECEIVED.

Report of Board of Health, City of Seattle, Fiscal Year Ending December 31, 1893.

Twenty-sixth Annual Report of the New York Orthopaedic Dispensary and Hospital, 1893-94.

Sixteenth Annual Report of the Presbyterian Eye, Ear and Throat Charity Hospital, Baltimore, Md. 1893.

Original Articles.

FLAT-FOOT.¹

BY E. H. BRADFORD, M.D.

If both feet of a standing person are placed side by side, they, with the two hollows which constitute the arch, form a circle, the outer sides of the feet forming weight-bearing rims. If one of the feet is removed and the whole weight is thrown upon the other, it will be seen that the semicircular rim, or the portion which touches the floor, becomes wider as the whole weight of the body is thrown upon the limb. This is due to the fact that the centre of the axis of the leg falls to the inner side of the weight-bearing portion of the sole; when one leg carries the weight, the ankle sags to the inside slightly, and the portion of the foot which touches the floor is correspondingly widened. This increase in the width of the contact portion of the sole is accomplished chiefly by the eversion of the foot in front of the medio-tarsal articulation and is checked by the tibiales muscles and the ligaments. If these muscles are weakened, the eversion of the foot will increase if weight is thrown upon it, the check becoming the ligaments which bind the scaphoid and metatarsals to the os calcis and astragalus.

If for any reason the muscles which hold the normal position of the foot are weakened, whenever the superincumbent weight becomes too great for the muscles to bear, the strain falls upon the ligaments, and this in time causes pain and tenderness. This pain and tenderness varies in severity, also in location. In some instances it is felt on the inner side of the foot in the region of the scaphoid, often at the head of the astragalus; sometimes the pain is referred to the outer side of the foot beneath the external malleolus. In some instances it is felt at the insertion of the plantar fascia to the os calcis, and sometimes a contracted band in the sole of the foot, similar in all probability to the fibrous cords to be felt in Dupuytren's contraction.

An examination of a dissected foot will show that the so-called arch of the foot is in reality two arches, an outer and an inner, united to each other firmly by ligaments, the outer arch being much lower than the inner. The outer arch consists of a truss composed of the five metatarsals, the cuboid and the os calcis; weight falling upon this passes through the astragalus, which sits upon the end of the os calcis. What may be termed the key-stone of this arch is the os cuboid, which articulates with the head of the astragalus slightly in front of the centre of pressure transmitted through the middle of the astragalus.

In the inner arch of the foot, the bow consists also of the curve of bone from the head of the first metatarsal and the os calcis, but the key-stone is slightly anterior to that of its outer arch, and is the scaphoid, which articulates with the astragalus on one side and the cuneiform on the other. There is also a transverse arch of the foot which, as has been pointed out by Dr. Goldthwait, is of some importance clinically. When weight is thrown upon the foot, the foot and leg can be compared to a leg with two claws, the weight not falling directly over either, but passing through the astragalus, which sits side-saddle, as it were, over the end of the os calcis. When the weight of the body is

thrown upon both feet, but little sagging is noticed. When the weight is borne upon one foot, either the body is inclined to the outer side so as to bring the centre of gravity directly over the outer arch, or the foot falls to the inside and the base is broadened, the inner arch descending and a movement of the inside taking place at the medio-tarsal articulation. This sagging inward consists of the dropping of the front of the astragalus with the scaphoid, that is, the so-called plantar flexion of the astragalus occurs. There is also a slight amount of inward movement of the heads of the astragalus and os calcis. This motion of sagging would continue until the heads of the astragalus and the os calcis rested upon the ground, with complete eversion of the foot if it were not that this is checked by ligaments and by the tibiales muscles.

Flat-foot is developed not only by the weakening of these muscles, as by a gradual stretching of the ligament. Individuals stand in what Annandale has called the attitude of rest. In this attitude, if the muscles are weak and not in action, the foot may be turned outward, and a greater amount of strain comes upon the ligaments which are not relieved by the tension of strong muscles. After a while the ligaments stretch, and the exciting cause remaining the same, a deformity is produced by alteration in the shape of the bones. It is probable, also, that faulty attitudes, positions with the foot turned out, are brought about, not only by occupation, but also by imperfect shoeing.

If a number of people be watched where they can be seen walking towards the observer from a distance, it will be noticed that peculiarities of gait are quite marked, that at least four per cent. will be seen to toe-out badly; that an equal number will toe-in with one foot; a smaller percentage will toe-in slightly with both feet; a large number will be seen to walk straight, that is, without eversion of the feet; a number will be seen to turn one foot out and the other foot in; the majority of children will be noticed to walk with the feet straight. The percentage of persons walking with the feet out is larger among women than among men, probably on account of the imperfection of shoes worn by women.

Anything which may weaken the muscular strength of the legs, or the muscles which are attached to the feet, will indirectly influence the causation of flat-foot. An increase of the superincumbent weight beyond the muscular strength may directly cause flat-foot. Rapidly growing children frequently show everted and flattened feet. Athletes who lift unusual loads in feats of strength develop flat-foot. In neither of these instances, however, is pain usually observed, provided the strain upon the ligaments is not too great. If, however, the weight of a rapidly growing child increases out of proportion to the muscular strength, or if the muscular strength of the athlete is weakened in his legs, strain comes upon the ligaments and pain develops. Certain occupations develop flat-foot, especially those which necessitate continued standing upon the feet. Flat-foot is characteristic of waiters, and is frequently seen in hospital nurses. An important indirect cause of the development of flat-foot is imperfect shoeing, particularly the lacing of boots tightly around the ankle and some distance up the leg.

DIAGNOSIS.

Although there is no difficulty whatever in the recognition of flat-foot in its pronounced stage, yet in the

¹ Read before the Surgical Section of the Suffolk District Medical Society, February 7, 1894.

earlier stages, especially in children, it is not infrequently overlooked. A careful examination is therefore important, as not infrequently cases of flat-foot are not recognized, but also other affections of the foot are considered and treated as flat-foot. The following means will enable the physician to avoid mistake:

If a sheet of white paper is blackened over the flame of a piece of burning camphor, a sooty surface is furnished on the sheet of paper. If the patient be directed to stand with the bared foot upon this smoked sheet of paper, and the foot quickly removed without disturbing the paper, an exact imprint of the foot will be seen. In the normal foot not only is there a hollow extending two-thirds of the width of the foot and fully one-third of the length, but the line on the outer side of the foot should be straight or slightly convex with the convexity outward. When there is eversion of the foot this outer edge of the foot becomes slightly concave with the concavity outwards. Where in addition to this the scaphoid and the metatarsals come more in contact with the ground, the hollow of the foot will be diminished in size; in extreme cases it may be entirely lost.

It is important to recognize the amount of eversion of the foot and to what extent that is to be seen. This can be determined by examining the patient from behind, placing the child erect upon a table and drawing a line down the middle of the leg as far as the level of the malleoli, and then from the heel upwards along the middle of the line of the tendo-Achilles. In the normal foot these two lines should make nearly a straight line; if there is eversion of the foot, or rather, if the os calcis is thrown out of place, falling inwards, these lines form a noticeable angle. Eversion of the foot can also be recognized by marking a line along the middle of the front of the leg, and also along the middle of the foot. These in normal limbs should form one and the same straight line; if there is eversion of the foot, they form an angle.

It is also important to determine, for the purposes of comparison, the height of the hollow portion of the foot, that is, the distance of the scaphoid from the ground, both when the weight is applied upon the foot, and also when no weight is so applied. This can be readily done by measurements by means of a small caliper. It will be readily seen that the amount of inward sag when weight is thrown upon one limb varies with different people. It exists to a slight extent in all persons normally. The amount of inward sag is, of course, proportionate to the amount of eversion, and it is desirable to determine this, and also to note its increase or diminution.

To recapitulate then, the examination of the foot should consist first, of a sole imprint; second, in a determination of the amount of eversion; third, the recognition of the depth of the hollow of the foot, and next, of the amount of inward and downward sag of the inner malleolus or inner surface of the scaphoid when weight is thrown upon the foot. It is also advisable to determine the amount of motion at the mediotarsal joint. In severe cases of flat-foot no inversion is possible, and the foot is rigidly held everted.

PROGNOSIS.

In growing children, flat-foot not infrequently corrects itself. In many instances after flat foot has developed, no pain is caused and no acute symptoms, or the reason that the muscles are sufficiently strong to

prevent exaggerated strain falling upon the ligaments although the bones are displaced. Ordinarily, however, the affection is one which tends to become aggravated and to increase, developing disturbances of the foot in old age which cause much discomfort. Malformation in the shape of the bones is also observed, particularly in the head of the astragalus and os calcis. Disarrangement in the length of the ligaments following faulty position also takes place.

TREATMENT.

The treatment of this affection necessarily varies according to the severity. In the lightest cases in children no treatment is necessary beyond the furnishing of proper shoes, and gymnastic exercises to develop the tibiales and muscles of the feet.

As is well known, the shoe should be made with a sole which is straight on the inside. In cases with tendency towards flat-foot, the sole should be made not simply straight on the inner edge but with the inner edge forming a curve with the concavity inwards; all tight lacing of the boots around and above the ankle should be avoided. Gymnastic exercises of the feet and legs are advisable together with massage. In cases of children with pain in the feet and ankles, or where an increase of the deformity and osseous change is to be dreaded, support on the arch of the foot is needed. This is also true in adolescents, and in cases in adults, where, as it is usually termed, the arch of the foot is breaking down.

From the before-mentioned facts it would appear that the cause of the development of flat-foot is the inability of the arches of the foot to sustain the superincumbent weight without yielding more than is normal. This yielding is manifested by a dropping of the heads of the os calcis and astragalus downward and inward. If this is not checked a sensitiveness and strain of the ligaments must follow. An examination of the foot will show that, to prevent this sinking downward and inward, support must be given to the foot, to prevent this descent of the os calcis and astragalus. It is manifest that if a support is placed under the hollow of the foot existing when no weight is thrown upon the foot, and this support sufficiently strong, it will prevent any sinking down and in, when weight is thrown upon the foot. Where the foot is not flexible and is fixed in a position of eversion and such support is supplied, the normal flexibility and position of the foot must be regained.

The treatment of flat-foot consists, therefore, in the severer cases, first, of means to restore the normal position of the foot, and second, in means to prevent the abnormal sinking of the foot under the superincumbent weight. The first of these can be carried out ordinarily by correcting the position of the foot with the hand and applying of a plaster-of-Paris bandage. This bandage can be removed at the end of a week and a second one applied. Ordinarily in the course of three weeks, a sufficient flexibility of the foot will be attained to render further treatment by fixation unnecessary. Correction can, if necessary, be done under an anæsthetic; and in the severest cases osteotomy is rarely necessary.

The second stage of treatment, namely, the furnishing of proper supports to the feet is one requiring some little attention. The supports vary according to the shape of the arch of the foot. In the lighter cases, a leather sole-plate can be made to answer. This pad

can be made in the following way: a piece of dressed cow-hide is cut of a size sufficient to extend under the sole and up the inner side as high as the scaphoid. It is moistened and placed in the shoe, and the leather adapts itself in a measure to the shape of the foot. This is trimmed, dried, and the edges smoothed off. A piece of steel, which is bent so as to arch somewhat more than the foot when the patient stands, fitting the inner arch of the foot when the foot is slightly everted and sustaining no weight, should reach from the front of the portion of the os calcis which strikes the floor to a short distance behind the head of the second metatarsal. It should have arms which extend transversely across the foot from the level of the scaphoid to beyond the proximal end of the fifth metatarsal. The leather-sole which is designed to protect the foot can be moistened at any desired part and molded upwards as may be desired to fit the steel, the steel truss can be riveted to this. When this is done, a strong support will be furnished which, properly made, will not be uncomfortable and can be placed in any shoe. The steel after it is fitted should be spring-tempered and should be sufficiently strong as to bend but slightly under superimposed weight. If necessary, a second strip can be riveted to reinforce the first.

It will be seen, however, that these plates are not as firm as what can be furnished by metal. Metal plates are more difficult to apply, but more lasting after they are thoroughly fitted. In order to understand the exact method of furnishing metal plates, it is necessary to call to mind the anatomical conditions of flat-foot. It will be seen that the heads of the os calcis and of the astragalus should be prevented from descending, that is to say, a pressure upward and slightly outward should be exerted under the inner arch. In order that this should not be painful, this pressure should fall where the bones are less prominent, and it will be found that this is slightly behind and below the scaphoid. As the transverse arch of the foot at this point slopes in a curved line downwards and outwards, it is manifest that the support should transversely have this same curve.

It must also be remembered that the so-called flat-foot is in reality an everted foot, and that whatever plate or support is worn, eversion of the front of the foot must be prevented. In lighter cases this is readily done by means of the ordinary shoe, which supports the foot in a measure laterally. In the severer cases, however, this will not be sufficient, and shoes are necessary so constructed that they force the foot in the position of eversion of the front part. A combination of a metal plate and these shoes will be needed in the severe cases of flat-foot. The metal plate, it is needless to say, should be made so as to press only where pressure is required and not where pressure causes pain. The shape of the plate necessarily depends upon the shape of the distorted foot, and the amount of flattening of the arch as well as the amount of eversion of the front of the foot. The plate is made from a cast of the foot. It can be made either of silicon bronze which can be polished, and will not tarnish, or of hard rolled aluminum plates, but the strongest and best plates are made of steel hammered upon an iron cast of the foot taken from the plaster cast. Care is necessary in taking the cast of the foot that it should be put as far as possible in a corrected position, otherwise the plates will not fit accurately. In some instances it is necessary that the plaster cast

be shaved so as to increase the pressure at a desired point; this is, however, a matter which a little experience will naturally suggest.

In the severest cases, however, something more than this is required, for the reason that no plate can be worn which exerts, in these cases, as much upward pressure as is desirable. A series of successively higher plates can be used, but the result can be more speedily obtained by the use, in addition to plates of moderate height, of the oblique made by raising the sole on the inner side of the boots by lifts which are shaved off to the inner side so that the outer edge is not raised at all. In an adult the thickness should be in severe cases as much as three-fourths to one inch on the inner side. When this is applied, the patient is obliged to walk on the outer edge of the foot and eversion is prevented. As the patient's symptoms improve, the strained ligaments become rested, the weakened muscles strengthened, this sole can be removed and a metal plate substituted.

The satisfactory treatment of flat-foot does not consist simply in furnishing a support to the arch of the foot, but in placing the foot in such a position that the superincumbent weight does not fall upon a widened surface of the hollow of the foot which eversion at the medio-tarsal articulation brings in contact with the ground, but upon the normal semicircle which the outer part of the sole constitutes, together with the ball of the foot and the heel.

HEMORRHAGE INTO THE PANCREAS AS A CAUSE OF SUDDEN DEATH.¹

WITH REPORT OF A CASE OF HEMORRHAGIC AND GANGRENOUS PANCREATITIS.

BY W. F. WHITNEY, M.D., BOSTON.

FROM its hidden position, the pancreas is, perhaps, the one vital organ which is most frequently overlooked at the post-mortem, and yet its lesions are so important that no autopsy is regarded as complete without a distinct mention of its condition. This is especially necessary in a legal examination, where a person in previously apparent good health is found dead. And in making an examination, it should be the invariable rule after inspecting the greater peritoneal cavity to separate the layer of omentum between the stomach and large intestine, and explore the lesser peritoneal cavity. At the posterior part of this cavity the pancreas should be seen, extending from the duodenum almost to the hilus of the spleen. It can readily be made out as a lobulated gland, the separate lobules of which stand out in slight relief against the fat tissue in which it lies imbedded; its more reddish-gray color also distinguishes it. Its shape is roughly like a hammer, the head being spread out along the duodenum, and the handle (or tail) stretching towards the spleen. Its length is about $7\frac{1}{2}$ inches, its breadth $1\frac{1}{2}$ inches, and its thickness $\frac{3}{4}$ of an inch. Its weight is $2\frac{3}{4}$ ounces. Its duct, which will admit a fine probe, opens with the common duct of the liver in the papilla, about six inches below the pylorus, in the duodenum. The mouth of this duct is slit-like, and is not easily found. In practice, a good way is to pass a probe down into the intestine through the gall-duct, which can always be easily found by its bile-stained wall;

¹ Read at a meeting of the Massachusetts Medico-Legal Society, February 7, 1894.

then to slit up the papilla for a little distance on this guide; and upon careful search, a little opening will be found about one-eighth to one-quarter of an inch from the tip through which the probe easily passes into the pancreatic duct. Occasionally the duct has a separate opening of its own into the intestine, and then it is more difficult to find. But pressure on the gland will often force out a drop of fluid on the intestine near the papilla, and thus its seat can be located. Examination of the duct should also always be made, as its occlusion or inflammation may be the cause of important changes in the gland itself.

After death the pancreas rapidly undergoes decomposition, and its cellular elements are frequently so altered that but little reliance is to be placed on the microscopic examination.

The pancreas is often the seat of cancer, and fatty degeneration is recorded, an increase of the connective tissue causing a cirrhosis of the organ; then, too, the duct is frequently tortuous and dilated, or the organ may be partly or wholly transformed into a cyst. All of these changes require time for their completion, and the physician has usually been called long before death, not always able, perhaps, to diagnose the exact condition, but, at any rate, convinced in his own mind that death, when it came, was from natural causes.

There have, however, been a series of cases reported, rare, it is true, where a person died suddenly after an illness of which the time had been fixed as varying from half an hour to twenty-four hours, and where the only lesion found was a greater or less hæmorrhage in and about the pancreas. Fitz, in his monograph on acute pancreatitis,² gives sixteen cases which he has collected. Since then (1888) only three or four cases have been reported, showing that the condition is one of the rarest that occurs.

From an examination of these cases, it appears that the pancreas is red, usually somewhat enlarged, and the outlines of the lobules mapped out by dark-red lines, for the hæmorrhage almost always follows the interlobular connective tissue, which can be seen microscopically to be infiltrated. The amount of blood poured out was, in the majority of cases, comparatively little, perhaps one or two ounces, not enough to be the direct cause of death. There are two or three exceptions to this, one recently published by Seitz, where over two quarts flowed out upon opening the abdomen, and the source of the hæmorrhage was from the region of the pancreas. And this is the only case on record in which the hæmorrhage is sufficient to account for death.

As to the cause of the hæmorrhage, we are as yet entirely in the dark, and also as to the reason of death. None of the theories advanced cover all the cases. One, that the flow of the blood over the cardiac axis causes compression of the great sympathetic ganglion and arrests the heart, does not seem to be borne out by the condition of that organ, which is found filled with blood. Another, that the hæmorrhage is due to disturbance of the central nervous system, similar to the hæmorrhages of the lung, meets with little support, as it was associated with this condition in only one case. To say that it is due to a trophic nerve disturbance is to confess our ignorance, as the physiologists have failed to demonstrate any trophic nerve other

than the vaso-motor nerve. And until this is done, their lesions can hardly be spoken about. The alcoholic habit has been marked in a number of the cases, but drunkards are not the only ones who have died in this way. Fat persons and lean ones have alike succumbed; the preponderance of the sex, however, is male, and usually past middle life.

What we know on the subject can be briefly summed up as follows: In rare instances, death has suddenly followed attacks of greater or less severity referred to the epigastric region. At the autopsy, a hæmorrhage of varying amount has been found in the pancreas and its vicinity as the only lesion.

This was the conclusion arrived at by Dr. F. W. Draper several years ago,² and, as far as I have been able to learn, nothing new has been added to it. His cases are the best single series that have ever been presented and give us more real knowledge than any others.

Although the above covers the entire subject of pancreatic hæmorrhage, I should like to trespass a few moments longer on your time and call attention to the subject of acute hæmorrhagic pancreatitis and its sequelæ, which have been so well worked out by Dr. Fitz in his monograph. I have seen a number of cases, and I have the specimen here of a case of this comparatively rare lesion of which I made the autopsy last week. In hæmorrhage into the pancreas the extravasation is the only lesion found. There are no evidences of an inflammatory condition in the organ, no cellular infiltration. In acute hæmorrhagic pancreatitis, in which the symptoms are of longer duration, from twenty-four hours to two or three weeks, usually, however, terminating within the first week, we do find alterations in the organ which point to an inflammatory condition. The organ, as a rule, is enlarged. There are single or multiple hæmorrhages throughout its substance, but they are not recent. The blood is not fresh; it has already been changed and very often it can only be made out from its coloring matter and not from the presence of any of the red corpuscles. With these there may be more recent hæmorrhages, and a greater or less infiltration of the connective tissue with round cells—evidences of an inflammatory condition of the organ. With this is also almost invariably associated a condition which is called fat necrosis. Throughout the fat tissue, especially in the neighborhood of the pancreas, in its interlobular fat tissue, in the root of the mesentery, at times in the omentum, and (in one case reported, all the fat tissues of the body were involved) are found opaque, white areas, quite distinct from the ordinary tissue. The presence of this necrosis has given rise to a theory, advanced first by Balzer, that it is the primary condition, and the hæmorrhagic pancreatitis is the secondary one. He considers that the changes in the fat tissue are due to disturbance in nutrition in fat people (and it should be mentioned that these cases of acute hæmorrhagic pancreatitis are very frequently associated with an overproduction of fat) in whom the fat has gradually undergone degeneration, has eroded the vessels in their neighborhood, and in this way the hæmorrhage has occurred. Fitz, on the other hand, regards the areas of fat necrosis as due to the action of pancreatic juice or some of its products on the fat tissue itself. Fitz's theory has this point in its favor, that in the greater number of cases the necrosis seems to start first in the

¹ Fitz, R. H.: *Acute Pancreatitis*. Cupples and Hurd, Boston, 1889.

² *Trans. Assoc. American Physicians*, vol. 1 (1886), page 243.

neighborhood of the pancreas, where it is always the most extensive, and when it is found in moderate degree it is in that region alone. This would point to its being a local condition, and one referable to the pancreas rather than part of a general condition. On the other hand, such a case as Formad's, where the fat necroses were found throughout the entire fat substance of the body, does point to some cause, central in origin, which causes its destruction in these small necrotic areas. It is possible that some ferment of the pancreas may be absorbed into the blood, and in this way, of course, receive a general distribution. For the present, we have to consider each of these as a possibility. There is no question about the association of these fat necroses with hæmorrhagic pancreatitis. For the causal relation, we shall have to have more light on the subject from the careful observation of future cases, and now that attention has been attracted to it on both sides of the water, it will undoubtedly be found.

In the specimen I have just passed about, we find that the hæmorrhagic pancreatitis is largely of the organ as a whole; the size is rather increased if anything, but there is no question that it is the pancreas that we have to do with. On the other hand, there is a series of cases (I made the autopsy in one last week), in which, apparently after one of these attacks of pancreatitis, the pancreas became entirely necrosed, remaining simply a slough. It lies almost as a foreign body in the place where the pancreas had been, and if it were not for the knowledge of what might occur, we should have difficulty in recognizing that it was the pancreas. The notes of this case, which occurred in the practice of Dr. Bush, have kindly been given me by him, and are as follows:

"The case is that of a widow, aged thirty-three, whose family history is good, with the exception of father, who died of cancer of the rectum.

"December 18, 1893. The history obtained was that for a year and a half she had eaten very little food, having had a very small appetite, and had kept up with stimulants. She would not eat regularly; in fact, the sight of food or the odor of cooking produced nausea. Yet at times she would help herself to sardines, cold chicken and such cold lunches as she could pick up from the cold closet or the refrigerator.

"When I saw her she was suffering from an attack of vomiting, accompanied by urticaria, which was very troublesome. The wheals were all over her body. The legs were somewhat swollen about the ankles. There was insomnia. The tongue had a light brown coat, and there was constipation. These symptoms, with the exception of the inability to sleep, rapidly disappeared upon treatment.

"There were no renal complications and no pain. There was a great deal of lassitude. Under appropriate treatment, these features disappeared to a marked degree, and she was able to take nourishment, the quantity of stimulants taken being diminished, and with the exception of not being able to sleep, she was feeling better than she had been for two years.

"January 14th, she was up and about the house as usual, and in the afternoon was taken with severe pain in the left hypochondriac region. The pain was so severe that it required large doses of morphine, given subcutaneously, to quiet it. At one time two grains of morphine were given within forty-five minutes, the pain being so acute. There was emesis and abdominal

extension. There was pain on deep pressure over the above region, and the bowels were constipated. The abdominal pain and vomiting lasted four days, accompanied with marked tympanites; at the end of that interval there were a few movements of the bowels. The general pain seemed to subside, but there was always pain upon pressure from the left back through to the front. The temperature was taken twice a day regularly, and sometimes oftener, but was never found to be higher than 101.8°. The rate of the pulse averaged 90. She was able to take a certain amount of milk in small quantities, and there was no vomiting for eight days, at which time she obtained some whiskey, of which she drank considerable, and the pain, distention and vomiting recurred. The matter ejected was of a green color, something like crème de menthe, and was mixed with mucus. The stools were extremely fetid in character. There were no urinary symptoms. Death occurred February 1, 1894."

At the autopsy, the abdomen alone was examined. Upon opening it, there was no evidence of any general peritonitis; the whole lower portions of the bowels were perfectly smooth and free, but on looking at the upper part the stomach appeared to be very much distended, and was greenish in color. On puncture, there at once came up a yellowish, thin pus, by estimate two quarts, and, exploring further, it was found not to come from the stomach, but from the lesser omental cavity. Then I suspected it was a case of pancreatic disease. The specimen was removed entire, and afterwards dissected. The stomach and duodenum were opened, and nothing of marked importance found. A probe was passed through the gall-duct, and by this guide the opening of the pancreatic duct was found, which is a little whitish track running about one-half an inch and then opening freely, with a slightly jagged edge, looking as if eaten off, into the cavity of the lesser peritoneum. In this lies a sphacelated mass, all that remains of the pancreas. A little portion of pancreatic tissue is still adherent to the intestine, and the black discoloration is evidence of the hæmorrhage which had taken place at some time into that organ. The pus had burrowed into the root of the mesentery on both sides, but had not broken through into the general peritoneal cavity.

On looking at the case, there is no question that the grave symptoms are of only two weeks' duration; that this extensive destruction of the pancreas could have occurred within that time, seems almost incredible. But we have reason to think that is probably the case. It is possible and even probable that the earlier attack in December was one of acute hæmorrhagic pancreatitis, and the condition continued until the necrosis of the organ began at the time concurrent with the second attack (January 14th), when the pus began to form and the peritoneal cavity to be distended. So this gangrenous pancreatitis is to be looked upon as the result of the hæmorrhagic pancreatitis.

There is still one other form of inflammation of the pancreas associated with the formation of the pus within the organ, which is spoken of as suppurative pancreatitis, and in which the disease is usually of long duration. It is a question, perhaps, of months—some deaths, however, occurring within the first month. But, as a rule, it has a longer course than acute hæmorrhagic pancreatitis. It is very rarely associated with any evidence of bleeding into the organ itself, and only rarely with any evidence of fat necrosis.

THE LEACH CASE.¹

BY THOMAS M. DURELL, M.D., OF SOMERVILLE.

On the evening of April 26, 1891, about six o'clock, I was called to the house of Dr. H. M. Leach, in Somerville, by the doctor, who told me that a servant-girl at his house had been taken with a fit. He said that he had used ordinary restoratives and that they had failed. I went with the doctor to the house and upstairs into a back room. At the head of the stairs we were met by Mrs. Leach, wife of the doctor, who said, "The girl is dead, she died while you were away." Dr. Leach then told me a most plausible story, which was corroborated by his wife, of the girl's previous ill health—that she had had a severe attack of the grippé, was a sufferer from chronic lung-trouble, and was subject to attacks of fainting.

I examined the heart, and found that it had ceased to beat. I also examined the pupils, and in so doing noticed that the nose was very cold.

The whole story was apparently so straight—and there was really no cause for suspicion, except a very remarkable degree of excitement on the part of the doctor and his wife—that I told them that I would sign the certificate, and went away.

Later in the evening, the relatives of the girl called upon me, and told me an entirely different story about her sickness and death. According to their account, the girl had been well up to within two weeks of her death, and they had known nothing about her sickness except what had been told them by the Leach family. They said that the family had told them that Mary was sick, and that the doctor had given her ether to extract a tooth, but that no one of her friends had been allowed to see her before her death.

While this was going on, the undertaker came and said that the bed-clothes and the girl's clothing was saturated with blood.

With these statements I deemed a further examination necessary; and on the following morning I made an autopsy in the presence of Drs. W. D. Swan and John F. Couch.

Autopsy.—Mary Murphy, twenty-two years old. About seventeen hours after death. Rigor mortis present. Dependent parts of the body bluish-purple color. Bloody froth exuding from mouth and nose. Right side of neck swollen. Pupils moderately and equally dilated. Abdomen prominent. Breasts small and flat; areolæ slightly marked; whitish-yellow fluid exuded from nipples on pressure. There was a quantity of gas in the peritoneal cavity. The parietal peritoneum was opaque and gray. The blood-vessels were injected, and covered over with yellow, flocculent masses. The omentum was dark and friable, glued to the intestines; loops of the intestines were matted and glued together. There was considerable grayish, turbid fluid in the pelvic cavity. The lungs were normal. The heart was empty; its right side was flabby; there was a firm mixed clot in the right side; otherwise it was normal. Spleen soft. Kidneys normal. Liver soft; there was a circumscribed patch on the external aspect of the right lobe, corresponding to a spot on abdominal parietes, covered with sloughing yellowish material.

On raising the uterus an irregular shaped hole was observed in its posterior surface. Immediately behind

this, lying transversely in the pelvic cavity, was a laminaria or sea-tangle tent. This tent was about the size of the thumb; one end of it was irregular in shape and corresponded exactly in shape to a hole which was seen in the walls of the uterus. The vagina was of a dirty slate color, and at the posterior commissure was an abrasion through the mucous membrane, the result of violence. The os uteri was patulous and was lacerated by many radiating fissures (the result of violent dilatation). The uterus was three and three-eighths inches in breadth at the fundus and four and one-half inches in depth. The internal surface was covered with decomposing material; and near the fundus were portions of placental tissue, also decomposed. The tubes were normal. The left ovary was normal; the right contained a corpus luteum in the state of a cyst of about the size of a cherry. The hole in the uterine wall was plainly to be seen on the inner surface, and extended directly through the substance of the organ. The bladder contained a small quantity of bloody urine; the organ was normal. The brain was normal.

The death was due to septic peritonitis, the result of an abortion.

The case has been tried twice; and both times the jury have returned a verdict of "Guilty." The first verdict was set aside on exceptions, and the exceptions on the second case are now pending.

Some very interesting questions were raised at these trials. The most important of these was the denial of the pregnancy by the defence, and the attempt to show that the material found in the uterine cavity was the result of a membranous dysmenorrhœa. A disease which Dr. Thomas says that he *thinks* he has recognized five times in his whole life, and of which Dr. Davenport, in his very valuable book on "Diseases of Women," doubts the existence; and yet a disease with which the men and women who testified for the defence, were very familiar; one young homœopathic man having had fifty or a hundred cases of it in a town in Maine of about six thousand souls. This claim was readily set aside; yet I am convinced that in another such case I should have a microscopic examination made by an expert.

Another question was as to whether a girl, pregnant for the first time, advanced three or four months in pregnancy could introduce a sea-tangle tent into her own uterus. This was strongly denied by the government; and yet a man of good standing in Boston came onto the stand for the defence and swore that from statements made to him by other women, he considered it not only possible, but probable, that this could have been done.

Another of the questions was as to the method in which the tent got into the pelvic cavity. My own theory was, that the tent was put in, and after a time an attempt was made to withdraw it, and in so doing the string was pulled out (the string was gone, the end of the tent split, and there were marks of forceps-teeth or something of that kind on the same end); that then the operator became frightened and made a desperate effort to get the tent with the forceps, and that in his efforts he pushed the tent through the already softened uterine wall. This theory was supported by the direction of the wound, that is, in the axis of the outlet. The defence claimed that the girl put it in herself, and that it worked its way up into the cavity (?) of the uterus and then ulcerated its way through. If this were

¹ Read before the Massachusetts Medical-Legal Society, February 7, 1894.

possible, the direction of the hole would have been just opposite to what it was.

The case was most obstinately fought by all the forces which money could provide, with able counsel and all sorts of so-called medical testimony; and yet a verdict was secured in both cases.

NOTE.— Since writing the above the Supreme Court has overruled the exceptions in the second case, and the prisoner has been sentenced to seven years' hard labor in the State Prison.

T. M. D.

Clinical Department.

TWO CASES OF LITHOLAPAXY.¹

BY GARDNER W. ALLEN, M.D.,

Surgeon in the Genito-Urinary Department, Boston Dispensary.

THE following cases seemed to present some points of interest, and may, perhaps, be considered worth reporting.

CASE I. A. S., fifty-seven years old, has been under my treatment for chronic cystitis and stricture at intervals for about four years. Micturition has been abnormally frequent and more or less difficult for many years, requiring occasionally the use of a catheter. In February, 1893, I advised internal urethrotomy, as the stricture, which admitted a No. 24 sound with difficulty, was not only a source of irritation, but interfered with catheterization. This proposition was declined by the patient, and a little later he purchased a catheter at a price which seemed to him a bargain. The first time he used it, it broke off in the urethra. After many futile attempts at removal he was seen by Dr. Burrell, who the next day did perineal section and removed that portion lying in the urethra, an inch or more being still left in the bladder. Not being prepared for cystotomy, Dr. Burrell desisted from further attempts at removal, and urged the patient to go at once to the hospital, which he declined to do. After this he suffered considerable and steadily increasing discomfort until July 16th, when I found him in great distress. Micturition was very frequent and difficult, and accompanied by an amount of suffering which was painful to witness. The passage of a sound immediately disclosed the presence of stone. The patient refused to go to the hospital, and as I was obliged to be away for several days I was unable to arrange for an operation until July 25th. On that day I did litholapaxy with the assistance of Dr. W. E. Chenery and two sons of the patient. The possibility of being obliged to cut for the stone suggested itself, and I also rather expected to begin with an internal urethrotomy; but as the lithotrite and No. 23 tube would pass, though with difficulty, it was decided not to complicate the operation. The patient took ether very badly, and it was impossible to get him thoroughly anesthetized. His constant writhing and the difficulty of breaking up the stone with its rubber nucleus sufficiently to pass through the small evacuating tube caused considerable delay, so that it was two hours and a half before the bladder seemed clear. The detritus removed consisted of fragments of phosphatic material mixed with pieces and bits of red rubber and, when dry, weighed 124 grains.

The patient was much relieved by the operation, although, of course, he still had his cystitis, considerably aggravated by the experiences of the last few months.

He passed fragments of stone and bits of catheter at intervals, and an attempt to pump out the bladder without ether about two weeks after the operation was unsuccessful on account of pain. Internal urethrotomy was done August 31st, and the calibre of the urethra brought up to 34. After recovery from this, the searcher still seeming to show fragments in the bladder, the patient was etherized September 28th and the bladder pumped out through a No. 31 tube. Only a small amount of sand was brought away, — no fragments. After this, repeated examinations with the searcher failed to reveal any foreign body, and for a while the patient's condition seemed much improved. But the cystitis gradually grew worse, in spite of treatment, until marked relief was afforded by injections of iodiform.

CASE II. The patient was a Syrian, twenty-eight years old, totally ignorant of the English language, and apparently of rather less than average intelligence. Through an interpreter it was made out with some difficulty and vagueness that when ten years old he was supposed to have a stone in the bladder and that an American surgeon in Beyrout wished to do lithotomy, but the parents would not consent. After that he had no symptoms until about a year ago, when he began to have frequent and difficult micturition gradually getting worse until he was obliged to urinate every fifteen or twenty minutes, with great pain. When he came to the dispensary, August 15, 1893, he was having a mild chill and complained of abdominal pain. The temperature taken a few hours later was normal. The urine was loaded with pus and was very foul, filling the room with a fetid odor. Examination with the searcher showed stone in the bladder.

The next day the patient was seen at his home. He complained more of abdominal pain, most severe in the left inguinal region. Examination of the abdomen was negative; the abdominal walls were retracted and hard, and not especially sensitive to pressure. No great importance was attached at the time to this abdominal pain, which was supposed to be of a colicky nature. The temperature was now 101°, the pulse rapid and rather weak, and the tongue dry. There was evidently constitutional disturbance, which was attributed to septic absorption from the bladder; and it was thought best to remove the stone and wash out the bladder at once.

The operation of litholapaxy was done under ether, with the assistance of Dr. R. F. Chase and ten or a dozen Syrians, friends and relatives of the patient. After the first crushing there was some difficulty in removing the lithotrite, and there was then first noticed a bright red tumor, the size of a large orange, behind the scrotum. It was rather a startling discovery, but was soon made out to be a prolapsed rectum. It was easily reduced through the very patulous anus, but immediately reappeared every time the patient strained in the least, which was very often. One of the assistants was detailed to hold it constantly up, but it prolapsed as often as his attention was distracted by anything of interest in the proceedings, and it proved quite an annoying complication, delaying the operation considerably. The interior of the stone was very hard and was crushed with difficulty. The operation was rather long, but the patient stood it well. The bladder was washed out with a boric-acid solution.

The stone was apparently about the size of an English walnut, and consisted of superficial layers of phos-

¹ Read before the Surgical Section of the Suffolk District Medical Society, February 7, 1894.

phatic deposit with a hard, dark-brown nucleus as large as a hazel-nut, presumably uric acid. A good deal was lost during the operation; the remainder, when dried, weighed 138 grains.

The next morning the pulse was fair, temperature normal, and tongue coated but moist. The character of the urine was improved, and micturition was less frequent and painful. The patient complained less of abdominal pain. In the afternoon there was recurrence of abdominal pain accompanied with hiccough. The abdominal walls were still retracted and the pain continued most severe on the left side. The patient vomited once and had no appetite. Temperature normal. The bladder was irrigated with boric-acid solution.

The second day after the operation, August 18th, the abdominal pain had increased. There was great sensitiveness to the touch, and tympanites had developed during the night. There had been no more vomiting. The tongue was moist. The temperature was normal; the pulse very rapid and weak. The urine had become foul again, but there was no difficulty with micturition. The bladder was washed out as before. The patient failed rapidly during the day and died at 8 P. M.

Looking back at this case after it was all over, it seemed evident that there had been from the beginning a grave and probably necessarily fatal abdominal complication which was not appreciated, partly on account of the difficulty of communicating with him and partly because the urinary symptoms not only overshadowed all others but appeared to account satisfactorily for his general condition. That the state of the bladder had at least a share in the causation would seem to be indicated by the apparent temporary improvement after the operation.

Medical Progress.

RECENT PROGRESS IN SURGERY.

BY R. L. BURRELL, M.D., AND H. W. CUSHING, M.D.

ETHER AND CHLOROFORM IN ANÆSTHESIA.

KÖRTE¹ has read an interesting communication on this subject, in which he shows the tendency to substitute ether for chloroform. The statistics, as presented before the Association of German Surgeons, were: 133,122 cases of chloroform anæsthesia, with 46 deaths, or 1 death for 2,894 cases. According to the statistics of Kappeler, 53 deaths occurred in 152,260 cases, or 1 in 2,878.

He gives a subcutaneous injection of morphia before anæsthesia. In using ether, as much as from 30 to 50 grammes (1 to 1½ fluid ounces) should be poured on the apparatus at first, but once tolerance is established, the amount required is small. The patient should be allowed to make several deep inspirations at the beginning of etherization. At the end of one minute, the mixture of gas in the apparatus becomes constant, consisting of 2.8 to 4.7 per cent. of ether, 16.6 to 18.7 per cent. of oxygen, and 1.2 to 1.7 per cent. of carbonic acid; in other words, less than a tenth part of the carbonic acid necessary to exert an injurious influence. Tolerance is established somewhat more slowly with ether than with chloroform, requiring seven and a half minutes. Since Dr. Körte has used ether he has anæ-

sthetized 600 patients, each operation requiring from 100 to 200 grammes (3.25 to 6.5 fluid ounces) of ether, according as the operation lasts one-half to one hour. All the patients bore the anæsthetic well. There was no slowing or weakening of the pulse, blood-pressure being sometimes even elevated.

However, there is a special action on respiration, the bronchial secretion increasing under ether, a rhoncus being at first produced, which would necessitate the suspension of chloroform anæsthesia, but which has no significance when ether is used. Vomiting was observed only sixty times in the 300 cases. The period of excitement is longer, but the sleep is calmer. In 32 cases only were the patients restless, exhibiting signs of discomfort. In one case, complete narcosis could not be obtained, though 430 grammes (14 fluid ounces) of ether were used. In three cases tetanic muscular contraction rendered the operation more difficult. In such cases about 20 drops of chloroform placed on the mask will cause the cessation of the contractions. After anæsthesia, the awakening is pleasant, and is soon succeeded by a natural sleep, due probably to the preliminary injection of morphia. It has been stated that ether produces nephritis; and in order to test the truth of this assertion, Dr. Körte examined the urine in a series of cases, before and after narcosis. Of these, 203 had no albuminuria either before or after operation. In seven patients there was albuminuria before etherization, but the nephritis from which it originated was in no way modified. Albuminuria was observed after anæsthesia in only six cases previously free from it. The influence of ether upon bronchial inflammation is incontestable, although it cannot be said that pneumonia is more frequent after ether narcosis. Recent bronchitis, however, should be considered a contraindication. Ether was given to patients suffering from empyema, in whom chloroform would have been dangerous on account of the heart. In such cases, nevertheless, the ether should be at once suspended as soon as a large quantity of fluid is observable in the bronchi.

As regards the inflammatory nature of ether, this is but a minor inconvenience, requiring only the simple precaution of avoiding the use of the Pacquelin cautery about the face, mouth, nose, etc. Patients who have submitted to both ether and chloroform, state that the sensations of anæsthesia by the former are more disagreeable, but the awakening is less painful. The writer's experience confirms this.

COCAINE IN HÆMOPHILIA.

Von Manteuffel² (Dorpat) reports the successful treatment of a severe case of prolonged bleeding following the extraction of a molar tooth of a boy aged twelve years. After two days of unsuccessful treatment by various devices and drugs it was determined to use a Pacquelin cautery. A preliminary injection of cocaine at three places in the gum about the site of the extracted tooth caused the bleeding to immediately stop. The injection had to be repeated, however, at intervals of five or six hours for some time before the bleeding was permanently controlled.

ON THE INDICATIONS TO BE DRAWN FROM THE URINE AS TO THE SAFETY OF ANÆSTHETICS.

At a meeting of the Clinical Society of the New York Post-Graduate Medical School, Dr. W. H. Por-

¹ Deutsche Med. Zeitung, February 12, 1894; The Universal Medical Journal, March, 1894.

² Deutsch. Med. Woch., 1893, No. 28.

ter² presented a paper on anæsthetics and the indications as to their safety, presented by the state of the urinary excretion. The paper is worthy of careful consideration, and he draws the following practical deductions from this chemico-physiological analysis of chemical phenomena :

(1) That ether and chloroform act upon the same principles, but with results developed by slightly different methods.

(2) That both are capable of producing death at the time of the anæsthesia; chloroform more frequently than ether.

(3) That ether causes as many, if not more, deaths than chloroform, but the fatal issue is delayed until the patient has been removed from the operating-table.

(4) That by a careful study of the density of the urine and its causes, we are in possession of exact information by which we can determine the precise nutritive condition of the system, and be forewarned as to the possible outcome of the anæsthesia. It also enables us to judge which anæsthetic is best adapted to the individual case in question.

(5) We are taught that neither ether nor chloroform should be administered until the glandular organs, in their necessarily damaged states, are put in the best possible condition to endure this extra strain. When this is a general rule, many cases that now prove fatal will be saved.

(6) It teaches that every public institution should have a paid physician who is competent to examine the urine, and determine through it the status of the physiological economy before giving the anæsthetic. It should also be the duty of this same physician to administer the anæsthetic, for he alone knows best which anæsthetic to select with a given condition of the system, and is also better able to guide the patient safely through the anæsthesia than one who knows nothing of the constitution of the patient except from a second party.

(7) While it is clear that death in some instances is directly due to the primary effects of the ether and chloroform, and in others to secondary effects, it should not deter us from using them, but stimulate us to be more thorough masters of their actions upon the system, and thus to guard against their ill-effects. When all this is accomplished, chloroform will probably hold the first place as an anæsthetic.

OPERATIVE PROCEEDINGS IN ADVANCED AGE.

Gibson⁴ has presented an interesting paper on this subject, having collected 65 cases, all aged seventy or more, with a mortality of 16; and of these, eight deaths were due to uræmia, the death occurring, on an average, on the fifteenth day. There is an absence of shock as the cause of death, and the use of iodoform is to be avoided in advanced age.

THE SURGICAL TREATMENT OF PULMONARY CAVITIES.

N. P. Dandridge,⁵ in a paper presented to the New York State Medical Association, presented this subject, and arrives at the following conclusions :

(1) A certain number of lung cavities can be successfully dealt with by incision and drainage.

(2) Tubercular cavities in the lower portion of the lungs—if single and superficial, and the general condition of the patient permits—should always be

opened. Cavities at the apex should only be opened where free and persistent expectoration is present, and has resisted treatment, and the rest of the lung is not involved.

(3) Abscess, gangrene and hydatid cysts should be opened and drained whenever they can be located.

(4) Closure of the pleura should be present before evacuation of a cavity is attempted.

(5) In cases of pyo-pneumothorax the fistulous tract should be explored, and any cavity freely laid open by the canter.

(6) Cavities that have been opened are best treated by packing with gauze, preferably iodoform.

(7) The further careful trial of such agents as iodoform, chlorine gas and chloride of zinc is desirable to determine as to whether the tubercular infiltration may not be modified by them.

(8) It is very desirable, for the further extension of surgical interference in pulmonary cavities, that the means of locating such cavities and of determining their size, and the exact character of the tissues that overlies them, should be perfected by further study, and for the accomplishment of this the surgeon must look to the physician.

GASTROSTOMY IN ONE STAGE.

F. T. Paul⁶ has contributed an illustrated article, and recommends the following method of opening the stomach at one operation, with power to feed the patient at once :

"The proceeding is very simple. The preliminary stages of the operation are conducted as usual, but when the stomach is picked up, a portion of it is drawn out of the wound, and two running sutures of fairly stout silk are passed in a circle round the site of the intended opening, with their ends in opposite directions, care being taken not to include the mucous membrane. The opening is then made, and, each side of it being grasped with artery forceps, one of my small (3-8 in.) intestinal glass drainage-tubes is inserted, and the ligatures are drawn tight and tied. The exposed portion of the stomach is now washed and returned into the abdomen, the external wound drawn together with fishing-gut sutures, and the ends of the stomach ligatures tied over two glass rods crossing the wound, in order that the stomach may be kept in close contact with the peritoneal surface of the abdominal wall. The wound is then powdered with iodoform, dressed with cyanide gauze and salicylic wool, and a bandage applied, a piece of jaconet being placed outside over the dressings to preserve them from becoming soiled. The experience of many bowel cases has shown me that these tubes separate between the third and seventh days; therefore, from the moment of the completion of the operation to the third day, the administration of food or washing out the stomach may be carried on with impunity. On the morning of the third day, the wound should be dressed, and from this time until the tube separates, and it is clear that good adhesions have been formed, discretion should be exercised as to the amount of food given and the care with which it is administered."

ENTERO-ANASTOMOSIS FOR MALIGNANT STENOSIS OF THE DIGESTIVE TRACT.

F. H. Markoe⁷ has contributed an interesting paper upon this subject, exhibiting two patients upon whom

² The Post-Graduate, July, 1893; Annals of Surgery, October, 1893.

⁴ Annals of Surgery, vol. xviii, No. 4, October, 1893.

⁵ Ibid., February, 1894.

⁶ Lancet, December 23, 1893.

⁷ Annals of Surgery, February, 1894.

he had operated for symptoms due to malignant stricture of the digestive canal. He summarizes as follows:

As a result of experience, we endeavor to operate as early in the disease as possible, or if debility is already present, postpone interference until, by means of systematic lavage with careful gastric, supplemented by rectal nourishment, the general condition improves. We have also learned:

- (1) That the size of the anastomotic opening must be huge on account of the tendency to contraction.
- (2) That in case of the stomach it should be as near as possible to the greater curvature and nearer the fundus than the pylorus, so as to be not only as far distant as possible from the disease, but at the same time, in the most favorable situation for the passage of the contents of the stomach into the intestine.
- (3) That the jejunum, about thirty inches from the pylorus, is the proper portion of the intestine to approximate, and that its opening should be placed midway between mesenteric attachment and extreme convexity.
- (4) That in the approximation the loop must be so arranged that its peristaltic wave corresponds with that of the stomach.
- (5) That the tide of opinion seems to favor a union which shall represent, as far as possible, that of the different anatomical layers (the ideal operation), rather than through the medium of artificial aids (Wolfier, Halsted, Barker, Abbe).
- (6) That as in all intra-abdominal operations, our manipulations must be so performed as to favor the slightest degree of ultimate adhesions between adjacent structures.

NON-PARASITIC CYST OF THE LIVER.

A rare and interesting case was reported by Müller at the twenty-second German Surgical Congress.⁸ It was probably a cysto-adenoma of the biliary ducts in a woman aged fifty-nine. The tumor was quite large, of slow growth, and at the time of operation (ten years after the growth was first noticed by the patient) it filled the abdominal cavity and part of the pelvis. It was mistaken for an ovarian tumor. At operation the tumor was found to be a large cyst containing over six litres of a chocolate-colored fluid (hæmorrhage into the cyst), and was attached to the liver, which appeared normal, by a thick, hollow pedicle. The cyst wall was thick, bled profusely when cut, and was formed of the remains of hepatic tissue with cystic dilated biliary ducts. The tumor was benign, that is, non-recurrent. The patient was free from recurrence at the end of one and one-half years.

SPHINCTERPLASTY AFTER EXTIRPATION OF THE RECTUM.

Willems, of Gent,⁹ in order to avoid the distressing rectal incontinence occasionally seen after extirpation operations, has attempted to form a muscular sphincter by following and modifying the suggestion of v. Hacker for gastrostomy and colostomy. He has successfully demonstrated his plan on the cadaver, but not on the living subject. It consists in bringing the resected end of the rectum out through a slit in the fibres of the gluteus muscles, near its origin from the border of the sacrum, and suturing it to the skin. This slit he would make two centimetres long and parallel with the muscular fibres.

⁸ *Beilage z. Centbl. f. Chir.*, 1893, Bd. xx, 66.

⁹ *Centbl. f. Chir.*, 1893, Bd. xx, 401.

This was reported in April, 1893. In March, Gersuney operated in Vienna by a method which was intended to overcome the same difficulty, namely, rectal incontinence.¹⁰ He solved the problem by twisting the proximal end of the resected rectum on its long axis till its lumen was sufficiently closed. This was determined by the introduction of the finger during the torsion. When this was accomplished the end was sutured to the skin. Gersuney operated on two patients suffering from rectal carcinoma. The sphincter ani was destroyed, but the rectal stump could be brought down to the skin. Both cases rapidly recovered without the sutures giving way. One had no incontinence from the first. The other at first was unable to control liquid dejections, but later (at the end of eleven weeks) recovered perfect control over the contents of the rectum.

These two procedures seem to offer a means of overcoming this painful and disagreeable sequel which has deterred many from operating on these patients, and they deserve consideration. They can be combined, perhaps, to advantage in some cases, since the Gersuney method is applicable to those cases where the excised end can be united to the skin in the usual way. The Gersuney method can also be used in forming an artificial anus where the intestine is resected so as to leave a free end.

INTESTINAL RESECTION.

Haasler reports a successful resection¹¹ where it was necessary to remove fifteen centimetres of the ileum with its mesentery, the ileo-cæcal valve, cæcum, vermiform appendix, ascending colon, hepatic flexure, and one-half of the transverse colon with the attached mesentery. The disease was an adeno-carcinoma which involved all the above tissues with the mesenteric lymph and retroperitoneal glands. The patient was well one year after the operation.

SUTURE OF WOUNDS OF THE LIVER.

At the recent Surgical Congress in Rome, Micheli¹² showed a case in which he had successfully sutured a wound of the liver. Laparotomy having been performed, it was found that the wound was situated on the convex surface of the left lobe, near the free margin; it was four centimetres in length and two in depth, and was directed vertically towards the lower margin of the organ. A moderate amount of hæmorrhage had taken place. The edges of the wound in the liver substance were brought together with five silk sutures and the abdomen closed. The patient (a woman) made an uninterrupted recovery and was discharged cured in twenty days. In a case of gun-shot wound of the liver, the author applied fifteen silk sutures and the hæmorrhage was so thoroughly controlled that no trace of bleeding having taken place could be found four days after the operation, when death occurred from peritoneal sepsis.

THE TREATMENT OF EXUDATIVE TUBERCULOUS PERITONITIS BY MEANS OF INTRA-PERITONEAL INJECTIONS OF STERILIZED AIR.

Nolen¹³ has arrived at the conclusion, after a number of observations, that curative results can be ob-

¹⁰ *Centbl. f. Chir.*, 1893, Bd. xx, 553.

¹¹ *Centbl. f. Chir.*, 1893, Bd. xx, 64.

¹² *Ref. Med.*, November 7th; *British Medical Journal*, December 2, 1893.

¹³ *Berl. klin. Woch.*, 1893, No. 34, p. 513.

tained by injecting sterilized air into the peritoneal cavity through the opening made for the evacuation of the ascitic fluid. He has tried this method in three cases successfully. In two cases the cure was permanent; in the third, the patient was too much exhausted prior to the treatment to have recovered.

The method is as follows: Sterilized air, contained in a glass jar, is expelled by means of hydrostatic pressure and passed through sterilized cotton, then through warm, sterile water, and finally passed, by means of the puncture needle, into the peritoneal cavity. This is carried out until the abdomen is tense. The process is reversed by removing the hydrostatic pressure.

RESECTION OF THE KIDNEY.

Kümmel has reported his experience in this method.¹⁴ After successful experimentation on animals, from which more or less of the renal parenchyma had been removed without detriment to their general condition or impairment of renal function, he operated on two patients. One was a woman forty-one years of age. The operation showed extensive suppuration, abscess formation and a renal calculus. About one-third of the kidney was excised. The patient was well at the end of three years after the operation. The other patient was a man fifty-four years old. Here a piece the size of a walnut was removed from the upper extremity of the right kidney. The remaining defect was closed by suture. He recovered from the operation in three weeks, but was not relieved. He was later found to have carcinoma of the bladder, which caused his death ten weeks later. The autopsy showed that the right kidney had perfectly healed, but was affected by interstitial nephritis. The excised portion of this kidney showed also the same process. In a third case, a woman aged thirty-four, an echinococcus cyst, the size of a hen's egg, was removed from the right kidney in a wedge-shaped section. The defect was closed by sutures. About one-half of the kidney was removed from the centre of its convex border without injuring the pelvis. The patient recovered. Other successful cases by Czerny, Bardenhauer, Socin and others, were reported by Kümmel.

Bloch (Copenhagen) has resected a small portion of a kidney which, on microscopic examination, showed bacterial infection. The operation was done for diagnostic purposes; and notwithstanding the infected condition the defect, which was closed by five or six cat-gut sutures, healed by first intention.

Küster has also removed an embolic infarction by resection from a patient aged thirty-two.

Kümmel recommends the convex border of the kidney as the most favorable site for resection, on account of the course of the renal vessels.

CHANGES AND DEGENERATIONS IN NÆVI.

Reboul¹⁵ states that in a certain number of cases the nævi disappear after birth. If any changes occur in them, or whenever they show signs of extension of malignant degeneration, they should be removed. They are most likely to undergo malignant degeneration of the melanotic variety. They should be regarded as infectious, and great care should be taken to prevent a local infection becoming general and leading to a fatal termination.

SURGICAL TREATMENT OF CERVICAL, THORACIC AND ABDOMINAL ANEURISMS.

C. B. Nancrede¹⁶ has presented the above subject to the Surgical Association, and submitted to them for their discussion the following propositions:

The Treatment of Cervical Aneurisms.

- (1) All methods should be supplemented by recumbency and diet.
- (2) Proximal compression, when feasible, should always be tried, and where the arterial coats are seriously diseased should supersede ligation.
- (3) "Needling" should supplement pressure when the case is progressing rapidly; possibly it is advisable in all cases suitable for compression, and is certainly to be employed where this method fails in cases with highly atheromatous vessels.
- (4) Proximal ligation, having been rendered much safer of late by the use of aseptic precautions, less absorbent ligatures and the avoidance of all injury to the arterial walls by employing the "stay-knot," is permissible when the arterial walls are relatively sound until experience decides whether or not "needling" is superior in its results.
- (5) Since recurrence after proximal ligation almost certainly results from non-deposition of white thrombi, and their maintenance in contact with the aneurismal wall from lack of proper changes in its lining, "needling" is then clearly indicated.
- (6) Where the location prevents proximal arrest of the blood current "needling" is the best operation; possibly distal compression—rarely feasible—might aid in the deposition of thrombi.
- (7) For the reasons already given, although occasionally successful, the indications for the permanent introduction of such foreign bodies as wire, horse-hair, etc., into aneurismal sacs are so much better met by "needling" that such procedures had better not be adopted.
- (8) The modern revival of the older method of extirpation of aneurisms should not be attempted for spontaneous cervical aneurisms.

The Treatment of Thoracic Aneurisms.

- (1) All methods should be aided by the employment of rest in bed and diet.
- (2) The permanent introduction of foreign substances should not be employed.
- (3) "Needling" should be tried, aided by distal compression, when feasible, during use of the needles; if this fails, distal ligation should be resorted to.
- (4) Distal interruption of the blood current by simultaneous ligation of the carotid and subclavian arteries may be tried.
- (5) "Needling" is indicated when complete or partial failure follows distal ligation.

The Treatment of Abdominal Aneurisms.

- (1) All methods should include recumbency and diet.
- (2) "Needling," when this can be done without injury to the hollow viscera, is the most promising plan.
- (3) Proximal or distal compression may be tried, with or without "needling," but to be effectual must be done under anæsthesia.
- (4) The permanent introduction of foreign bodies into the sac is inadvisable (see proposition No. 7, Carotid Aneurisms).

(To be continued.)

Reports of Societies.

SURGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

CHARLES L. SOUDDER, M.D., SECRETARY.

REGULAR Meeting, Wednesday, February 7, 1894,
DR. ABNER POST in the chair.

DR. G. W. ALLEN read a paper entitled,

TWO CASES OF LITHOLAPAXY.¹

DR. H. L. BURRELL: The patient that Dr. Allen has so successfully operated upon came under my care last March with a catheter lodged in his urethra at the junction of the membranous and bulbous portion. The patient showed us the portion of the catheter which was broken off, and which was one of those dangerous catheters sold by pharmacists, composed of rubber and sulphur, which become friable upon keeping.

He was advised to have a perineal section done and the catheter removed. This, however, he declined, and went home. I was induced, much against my will, to try to extract the catheter at his home per urethra. A portion of the catheter was removed by forceps, but it finally broke off, and undoubtedly a piece of the catheter slipped into his bladder and formed the nucleus of the stone which Dr. Allen has removed. The operation was completed by opening his perineum and washing out the bladder, with the vain hope that the fragment would be removed. He was told that it would be necessary to have a further operation performed in order to secure the lost end of the catheter that rested in his bladder. This he declined, and he is, of course, to be congratulated on the successful removal of the fragment and the calculus which has formed about it.

DR. WATSON: Dr. Allen's first case, that in which a bit of a red-rubber catheter formed the nucleus of the stone, suggests a matter in connection with the choice of operation for stone which is interesting, I think, and which I feel should receive rather more attention than it sometimes does. I refer to the method of removing stone after rapid fragmentation through the wound of an ordinary external perineal urethrotomy. This method, which dates back for a long period, has been advocated by Mr. Reginald Harrison, and still more recently by Surgeon Major Keith, under certain conditions, the most important one being obstructive prostatic hypertrophy of such nature as to make the passage of instruments from the meatus especially difficult; or again, where there is present some condition which makes the stone very difficult to crush, such as its having a foreign body for a nucleus, a soft substance, like that in Dr. Allen's case, or a bit of lead, for example, or in cases in which there is a large stone, the crushing of which by the ordinary means would require a long time. Under such conditions this very simple perineal operation recommends itself, and the surgeon should not hesitate to adopt it, even after having begun to do the usual crushing operation, whenever these conditions arise. The only death I have had thus far from operating for stone would, I think, very likely have been averted had I employed this method of operation. It was a case in which the prostatic urethra was exceedingly difficult to pass a lithotrite through without some injury, owing to the encroachment of an enlarged prostate, and I think the deep

urethra was slightly wounded, and that death was the result, probably, of the injury.

DR. POST: It is a little curious to me to see how nicely Dr. Allen succeeded in pulverizing that catheter. My own experience would lead me to think a catheter was an extremely difficult thing to pulverize with a lithotrite. Generally enough elasticity remains to make it difficult to break up into small enough fragments to remove through the ordinary apparatus.

DR. E. H. BRADFORD read a paper on

FLAT-FOOT.²

DR. HARRINGTON: For myself, I have always liked the metallic foot-plates better, for the reason that the other foot-plates, I think, are apt to give way. You often get relief from a new pair of well-fitting boots, but as they are worn and sag they get misshapen, and cease to give relief. I think the same trouble comes with plates which are not metal. The subject has been treated more from the anatomical point of view, and without much reference to symptoms. They who do not study flat-foot might expect all feet which need support to show deformity. We sometimes get the most painful feet with very little of what we would call flattening, very little that would show from tracing or measurement.

DR. FITZ, of Cambridge: In order to test the question of the occurrence of flat-feet, I have been making arrangements to get footprints of Indians, negroes and whites on a large scale, to see how far the occurrence is distributed. For that purpose, I have experimented somewhat as to a method for quickly taking large numbers of footprints, and have devised one which may be of interest to the Society. I have in mind getting the ratio between the length of the feet and the breadths of the ball of the foot, the arch and the heel, and summing this up for the different races, to see whether there is a distribution of flattening, and how it occurs in relation to age as well as to nationality, and especially to see if it occurs more or less frequently among those wearing an arch-supporting shoe.

DR. NEWELL: I have been very much interested in hearing Dr. Bradford's very interesting observations, and also to see the method of making the various impressions in the way just described by Dr. Fitz. I have been always very much opposed to the use of plates in any form for flat-foot. It seems to me these observations under the varying degrees of pressure show conclusively that the arch of the foot is an elastic movable apparatus that changes its height in accordance with the amount of weight you bear upon it. Although I have seen a good deal of flat-foot in the physically reduced cases, it seems to me the pain was due to abnormal tension, to weakening of the ligaments, and the condition has been one of wasting away of muscles or ligaments or both, and one which in almost all cases in my experience has shown marked improvement in improved physical conditions. I think there is no question that as a temporary means of relief a plate for flat-foot is useful except that it has the disadvantage that being placed under the foot it presents a very abnormal condition in the shape of a rigid, inflexible arch that keeps up a constant pressure atrophy, and patients who have come to me wearing flat-foot plates I have known to suffer a great deal from pressure atrophy; so that it seems that except as a measure of

¹ See page 323 of the Journal.

² See page 377 of the Journal.

temporary relief the use of plates of any kind is contraindicated.

DR. HARRINGTON: We use foot-plates a good deal as we use crutches; we do not use them after the patient can get along without them. Among the severe cases of flat-foot there are many cases in which it would be absolutely impossible to get relief without foot-plates. I believe most thoroughly in the proper position of the feet, proper methods of walking, etc. The danger from pressure is not great. If the pressure is improper we get callosities and we soon find it out from the patient. The foot-plate is only a temporary means of support. Many patients wear plates for a few months and then give them up entirely or use them only from time to time.

DR. GOLDTHWAIT: Very little remains to be said upon the subject of flat-foot, after Dr. Bradford's paper, as flat-foot is generally understood, that is, an obliteration of the longitudinal arch of the foot. Much less attention has been paid to the transverse arch which is an anatomical fact, and which at times becomes obliterated, and requires treatment of as definite a nature as in the cases in which the longitudinal arch alone is flattened. It is to this special point that I wish to confine my attention.

Normally, across the metatarso-phalangeal articulation is a slight arch which becomes obliterated as the weight is borne upon the foot, but which re-forms as soon as the weight is removed. In this way the weight is received upon the inner and outer sides of the foot. The normal tracing, or impression, of the foot has this sharp re-entering angle with this tongue running up under the ball of the foot. When the arch is obliterated this sharp angle is lost, and the weight is borne more upon the middle of the foot. This condition is almost invariably present in the cases of metatarsalgia, and the acute pain is at once relieved by the correction of the arch. A specially constructed metal plate or leather pad has been used in this condition.

DR. BRADFORD: I am glad Dr. Newell brought that point out, for I meant to have laid stress on the fact that it is important that patients with flat-foot should be treated with gymnastic exercises and massage. The treatment of flat-foot varies according to the severity. In the mildest cases shoes and gymnastics are all that is needed. In the less mild cases I think some slight means of throwing the foot over are needed and in these cases the soft plate is sufficient. In the severer cases, temporarily a strong support is important, and I am inclined to think we shall be able to get along very well with the leather strengthened by steel. The strong metal plate will probably be needed in the heavier cases. I do not quite agree with Dr. Newell that this necessarily causes pain. If adjusted right, I do not think pain is caused. Although, of course, there is danger of muscle atrophy during the use of a plate, the same may be said as to the application of any appliance, which is only to be used when this is unavoidable.

DR. NEWELL: I have been misunderstood if I made any one think I thought the plate caused pain. My experience has been that the plate relieves pain. What I referred to is pressure atrophy. I have seen patients who have worn rigid metal plates a long time and the muscles and soft parts have been very much atrophied from non-use and constant pressure over a rigid metallic arch. What I have always found best is correction of position and the use of flexible springy supports,

especially the leather ones. I once had a baby two years of age brought to me with a beautiful pair of aluminum bronze flat-foot plates in its shoes.

DR. O. K. NEWELL read a paper on

THE INTERMITTENT RAPID DILATATION OF URETHRAL STRICTURE.

The paper called attention to the generally admitted fact that all strictures which can be at once treated by the introduction of metallic sounds are best effected by gradual dilatation. That true organic urethral stricture, like œsophageal and rectal strictures, is incurable, and let alone tends with greater or less rapidity to recontraction. The paper then described a method of treating all very small calibre strictures where no progress with metallic sounds can be made, or where they have progressed to partial or complete retention. This method consisted in using a series of dilators similar in operation and construction to Dr. Newell's divulsor described some time ago. These dilating staffs range in size from No. 10 F. to No. 30 F., and their purpose is to do away with the old operation of immediate full divulsion by intermittent rapid dilatation, say first from Nos. 10 to 14 or 18, then from Nos. 18 to 20 or 24, and so on. All strictures are thus made practically amenable to gradual dilatation. No detention in bed is necessary, even where there is retention, and patients are able to avoid being incapacitated from work. Also when the dilating staffs are passed in on the guide, the danger of making false pockets, as with a free metallic sound in small calibre strictures is avoided and the operation is made mechanically certain. It being only a question of how much stretching to do at each sitting.

DR. WATSON: I should like to ask in how many cases Dr. Newell has tried this method.

DR. NEWELL: I have adopted it now during the last two and a half years. I have in that time treated no case of stricture in any other way. I suppose I have treated seventy to eighty cases in this way. I never yet have had any case that has not been able to keep at work. It is true, as Dr. Watson cites from Sir Henry Thompson's and his own experience, that slight disturbance of very small strictures often causes more trouble than radical interference. But by this method we do not interfere slightly, but moderately. Dilating, for instance, with retention, from the filiform up to Nos. 16 or 18 F. This relieves the retention, but is not violent enough to disable the patient, who may go about his work after the procedure.

DR. WATSON: Would you claim greater immunity from mortality when this method is used?

DR. NEWELL: I do not think there is any mortality from divulsion.

DR. WATSON: The reason I ask this question is to bring out one matter with which Dr. Newell's experience in this series of cases differs widely from that of some other surgeons; for example, from Sir Henry Thompson's, who states very clearly, what other surgeons have also held and what I find to be true in my own operations, namely, that frequently far greater constitutional disturbance and more serious symptoms arise (especially in cases of the tighter strictures) after an incomplete operation than you will have after a full divulsion or internal urethrotomy or dilatation, etc. If Dr. Newell can show in a large number of cases that that is not true, it will be of decided interest to me. When I first began to do rapid dilatations and internal

urethrotomies, I used to be a little afraid of carrying the operations to their full limits; but I found that the least constitutional disturbance occurred when I at once fully restored the calibre of the strictured portion of the urethra to its normal size, and the most serious followed upon partial restoration only.

I do not quite understand whether Dr. Newell classes this method which he describes as divulsion or dilatation; nor do I understand what Dr. Newell means when he says that the operation of internal urethrotomy is not applicable to structures of small calibre — for, of course, it is well known, that with the instrument of Maisonneuve any stricture through which a filiform bougie can be passed can readily be divided by an internal urethrotomy.

DR. DOUGLAS GRAHAM: These cases are entirely out of my line of practice. The method of Dr. Newell is evidently a sort of internal massage. Several years ago some foreign surgeons reported a number of cases of stricture of the urethra successfully treated by massage after the so-called failure of other means. As soon as a bougie could be passed through the stricture this made a good substratum over which to use massage from the outside. By this combined method of gradual dilatation from the inside, and massage externally, thickening, narrowing and spasm were got rid of. Where practicable it would certainly seem to be a rational and natural procedure. But the mere mention of massage in such regions is sufficient to incite in some minds the idea of immorality, as it probably reminds them of some indiscretion of their youth which must have been a very different thing from *massaging* a stricture. "Evil to him who evil thinks."

DR. NEWELL: Intermittent dilatation; no divulsion is done at all. This is not a divulsor. I think it has been the experience of surgeons in the last few years that when they sterilized things there was very little heard of the so-called catheter chill. When I have seen it, it has seemed to me to be of the reflex class.

Dr. Newell said in answer to questions that this method was applicable to strictures regardless of their situation. One had to go slowly with penile ones, and there was rapid progress with the others usually.

He was opposed to cutting a stricture under any form. One must have a pretty large stricture in order to cut it. The mere linear incision of a stricture only added a cicatrix to what was already a cicatrix.

MASSACHUSETTS MEDICO-LEGAL SOCIETY.

F. W. DRAPER, M.D., SECRETARY.

REGULAR Meeting, February 7, 1894, DR. Z. B. ADAMS, the President, in the chair.

DR. T. M. DURELL reported

THE LEACH ABORTION CASE.¹

DR. W. F. WHITNEY: In regard to the question of membranous dysmenorrhœa. If the examination of the membrane shows the presence of villi of the chorion, that is indubitable proof of the existence of a pregnancy, for these are only formed from the ovum; they can never be formed by the uterus itself or by any of the processes of menstruation. On the other hand, a membrane is not infrequently discharged from the uterus composed of cells of a character like those in the decidua of pregnancy, the uterus being one in

which, as far as can be learned, no pregnancy has taken place. I have made some observations of this kind myself, in which, from the structure of the membrane, I supposed pregnancy to have been present; but this diagnosis later events proved to be an error. The presence of villi of the chorion, which are formed alone from the ovum, and not by the uterus, is the only indubitable proof of pregnancy.

DR. W. A. DOLAN: I have had one case of abortion in which the opening was through the cul-de-sac into the peritoneal cavity, and death, as in this case, was due to septic peritonitis. I took the precaution to have the tissue of the uterus examined microscopically, so that if there had been any question of pregnancy we could have had that to fall back on.

DR. W. F. WHITNEY then presented a communication on

HÆMORRHAGE INTO THE PANCREAS AS A CAUSE OF SUDDEN DEATH.²

DR. J. G. PINKHAM: I am not able to throw any light on this subject. I am very much interested in the paper. I have witnessed autopsies in two cases. The first one was some years ago, before this subject was particularly understood, and the autopsy was made by one of my fellow practitioners. The case was not fully understood at that time, but as I remember it, the pancreas seemed to be simply a mass of blood-clot. The mass was as large, perhaps, as a man's arm. I judge now from thinking of the case that the hæmorrhage into the tissues was very extensive indeed, so that the organ was very much enlarged in this way, and was extremely brittle as we took it out. The case was sent to some one in Boston, but was not diagnosed as it would be at this time. It was supposed that the hæmorrhage was in the neighborhood of the pancreas, and that that organ was wasted, destroyed by disease, but I think now that the hæmorrhage was in the substance of the organ, and that that produced the peculiar condition that was observed.

In the second case I was the attending physician. The patient was a baker, a fat man. He was taken with violent epigastric pain, vomiting and great depression. He was treated, as those cases usually are, with remedies to meet the symptoms, and died after about five days. The autopsy showed the condition which has been described here, the opaque white spots which are not limited to the pancreas, but were visible in the omental fat, and very generally throughout the abdomen. I think other portions of the body were not examined because that was before the attention of the suburban practitioners, at any rate, had been called to this peculiar condition of acute pancreatitis with hæmorrhage. But that evidently was the disease, and that specimen was sent to Dr. Whitney, and upon his diagnosis the certificate of death was based. As a matter of interest, there was some dissatisfaction among the friends in regard to the fact that the man died from such a cause, and the case was reported to a distinguished homœopathic physician of Boston, who said there was no such disease.

DR. B. H. HARTWELL: I have never seen a case of what has been described by Dr. Whitney, but I think that we are under a great deal of obligation to him for bringing anew this matter to our minds. We see a great many cases of sudden death, and I am sure

¹ See page 382 of the Journal.

² See page 379 of the Journal.

we are puzzled sometimes after an autopsy to state the absolute cause of death. I am sure hereafter we shall not only look more carefully for disease of the pancreas in our autopsies, but shall be better able to tell whether the pancreas enters as a factor in the case, and if any of us should fail to find the pancreatic duct, I am sure there would be some consolation to us in the fact that so eminent a pathologist has difficulty in finding it.

DR. F. W. DRAPER: I am reluctant to say a word, because all the necessary words have been said either by Dr. Whitney or by the other members of the Society. Two practical points, however, have occurred to me in listening to what Dr. Whitney has said: one is that all sudden deaths by natural causes are not to be set down hastily as deaths by "heart disease"; and the other is that an autopsy is not a complete autopsy unless it includes the examination of the pancreas; that it is incumbent upon us as medical examiners to be thorough in our work, and where occasion comes to make an autopsy, to make it so that it can be worthy the name.

So far as these cases of pancreatic hæmorrhages are concerned in their relation to sudden death, I think the anatomical diagnosis is not at all a difficult one when the lesser omental cavity is opened as it always ought to be for inspection; the case declares itself almost at once; there is no reasonable room for doubt as to what one has before him. The organ itself, normally a pale yellowish white, is in these cases discolored red, and on either side and around the end of it will be found in the retro-peritoneal connective tissue an infiltration of blood that is unmistakable, which one cannot but see if he has ordinary eyes; so that it is not a matter of difficulty in diagnosis, but ordinarily a matter of neglect in the pathologist, that these cases escape observation. In some 4,000 cases of death of all sorts, I have seen 19 cases in which there was some pancreatic hæmorrhage, but in not all those nineteen was it to be assigned as the one cause of death. It was in company with other conditions, conditions relating to the liver or to the kidneys, or to the heart or to the lungs, which were complications, so to speak, making the post-mortem diagnosis a little more difficult; but in some nine or ten cases there was no other cause of death. Those were the purely typical illustrative cases Dr. Whitney has described so well. They are the cases of persons found dead, about whose clinical history one knew nothing. In only one instance that I recall at this time did I know the clinical side of the case, and that was, as it happened, the first case I ever came upon. That has been published. I will only state the facts that the symptoms were precisely as Dr. Pinkham has related—great depression, amounting almost to collapse, epigastric pain, with nausea and attempts to vomit, which generally were unsuccessful, a sinking which resulted in death in forty-five minutes after the onset of the attack. The patient, a man, died in the carriage on the way to the hospital, having been seized suddenly, and the appearances were typical and conclusive, nothing else being seen that was abnormal except this pancreatic hæmorrhage into and around the organ.

DR. Z. B. ADAMS: It seems to me that there are two very valuable points for the medical examiner in the study of this thing, and the first of these is that sudden death may occur from pancreatic hæmorrhage. It should be borne in mind, and when the medical

examiner is called to a case and cannot come to any positive conclusion about it, he should not be content unless he examined this organ after making the usual examination of the heart or other organs. He should not forget that sudden death may occur from hæmorrhage into the pancreas, something, I think, few of us have heretofore taken into account, but since attention was called to it we have waked up to that. Another point is in reference to the cause of death. That, as Dr. Whitney has said, is still a very obscure point; but it seems to me, if many of these cases should come into our hands, we should soon solve that problem. The cases are so rare, however, that we know little or nothing about that. Speaking of the other forms of pancreatitis, suppurative, etc., I am reminded that some fifteen years ago I had a very stout patient who died after a short illness. I secured an autopsy, and found pus at the head of the pancreas, but at that time I had heard nothing about this acute form of hæmorrhagic pancreatitis, and really did not know what to call it. I found quite a sac of pus there, and that, to me, appeared to be the only lesion. The symptoms were those of distressing pain in the epigastrium, with vomiting and inability to retain food, constipation, and that was all. He died within a very few days, greatly to my surprise, as I could see no sufficient reason for his death, and that was what I found. As soon as Dr. Fitz's paper came out I said, "There was my case."

DR. W. F. WHITNEY: In making a post-mortem examination, I should say the pancreas ought to be examined before the heart or any other viscera have been disturbed, because one is very apt to get a false extravasation, which might mislead as to the source of hæmorrhage. The rule should be, after the greater cavity of the peritoneum had been inspected, the lesser cavity should be opened and the pancreas examined at that time.

In reply to Dr. Adams's question, I would say that, personally, I have not seen any cases of sudden death from hæmorrhage into the pancreas from violence or a blow. There are some cases where violence in the neighborhood of the pancreas has been found to be followed by a hæmorrhage into the organ. Dr. Fitz has recorded the autopsy in the case of a man who had a railroad injury, and the splenic artery or artery of the pancreas had been torn; he found evidences of fat necrosis in the neighborhood of the pancreas; this had developed very speedily, and is one of the strongest arguments in support of his theory that the necroses are dependent upon lesions of the pancreas.

There are a number of cases reported of extensive injury of the pancreas in which patients have recovered without untoward symptoms.

THE NEW YORK NEUROLOGICAL SOCIETY.

STATED Meeting, held at the New York Academy of Medicine, Tuesday evening, March 6, 1894, DR. M. ALLEN STAER, President, in the chair.

DR. J. ARTHUR BOOTH presented

A CASE OF EXOPHTHALMIC GOITRE: THYROIDECTOMY.

The patient was a female, aged twenty-four, single. Family and personal histories negative. About two years ago the woman first noticed an enlargement of the throat, and three months later the eyes became affected. The patient is positive that there were no

heart symptoms until six months ago, when palpitation, throbbing of the vessels of the neck, shortness of breath and flushing of the face appeared. All these symptoms gradually increased in severity, and the patient became irritable, easily excited, anxious and unable to sleep because of the tumultuous action of the heart. When the woman first came under my observation both the eyes were very prominent, especially the left, and the lids did not follow the movements of the eyeballs (Graefe's symptom). The pupils were moderately dilated, reacting to light and accommodation. Fundus normal. Vision not impaired. The enlargement of the thyroid body was marked, the right lobe being the larger. Pulse 150, of high tension. Apex-beat of the heart diffused; no murmur. Respiration 24. No tremor of hands or fingers. Examination of urine negative. The patient was given daily applications of galvanism, and received one two-hundredth of a grain of aconitia twice daily, and fifteen grains of iodide of potash three times daily. She was also instructed to practise full inspiration frequently, and to rest as much as possible during the day. Under this treatment there was decided improvement in the symptoms, but only temporary in character, and on November 8, 1893, thyroidectomy was performed by Dr. B. F. Curtis at St. Luke's Hospital, the right lobe of the thyroid being removed. The patient made an uneventful recovery, and during the four months that have elapsed since the operation there has been a decided improvement in all her symptoms. The pulse-rate now ranges between 96 and 110. Many of her nervous symptoms have entirely disappeared. She sleeps well, does not suffer from palpitation, and is able to attend to her housework. The eyeballs are much less prominent. The left side of the thyroid has diminished in size to a slight extent since the operation.

DR. ROBERT SAFFORD NEWTON presented

A CASE OF EXOPHTHALMIC GOITRE: THYROIDECTOMY.

The patient was a girl aged twelve. In this case almost complete extirpation of the thyroid was performed, only a small supernumerary lobe being left. Since the operation, the exophthalmos, which was very pronounced, has almost entirely disappeared. Before the operation the pulse-rate was 180, and the child suffered from cyanosis. The systolic and diastolic heart-sounds were almost synchronous. The operation was performed by Dr. Fowler on October 21, 1893, and the child was out of bed three days afterwards. Her pulse now averages about 100. She is able to attend school, and is much improved in every way.

The PRESIDENT stated that the absolute contrast between the symptoms in exophthalmic goitre and myxœdema makes it seem very probable that many of the symptoms of the former disease are due to an excessive secretion of the thyroid gland, just as those in myxœdema are due to its suppression. Up to the present time there are not enough cases on record to permit us to make definite statements regarding it.

DR. GEORGE W. JACOBY presented

A CASE OF PROGRESSIVE MUSCULAR ATROPHY OF THE PERINEAL TYPE.

The case was that of an illegitimate child, a girl aged twelve years. The mother states that the child's father was a large, well-proportioned man, but that he

was rejected for military service abroad because his muscles were weak. This is the only hereditary factor obtainable. The history of the case, in brief, is as follows: There was no trouble at the child's birth. When two years of age, some months after an attack of measles, she complained of pain in the lower extremities, which was so severe that she could not stand. This lasted about six weeks, and from that time on she appeared to have difficulty in walking. She has always been able to move her legs in every direction. When she was four years old it was noticed that one leg was weaker and thinner than the other. About one year ago it was first noticed that there was an atrophy of the thigh on the side opposite to that of the affected leg. She holds the leg in a stiff and clumsy position. There is a lack of symmetry between the two buttocks. She had marked lordosis and slight lateral curvature. The muscles of both thighs are in a continual state of unrest, almost like fibrillary twitching. The right foot is in equino-varus position. There are no sensory disturbances. There is partial reaction of degeneration in the affected muscles. The arms are not affected. The superficial reflexes are normal. The tendon reflexes are present, but somewhat reduced on the affected side. In conclusion, Dr. Jacoby said that while he regarded the case as one of progressive muscular atrophy of the perineal type, it was not an absolutely typical one, inasmuch as the atrophy, although bilateral, is asymmetrical, one leg being affected and the opposite thigh.

DR. B. SACHS said he agreed with Dr. Jacoby's diagnosis. The atypical distribution of the atrophy should not militate against the diagnosis, as that is really the last thing to be considered, although still so much insisted on by many writers. The distribution of the atrophy is largely a matter of chance. He has seen six cases of progressive muscular atrophy of the perineal type, which is, perhaps, the rarest form of the disease. In none of these was there a cross-distribution of the atrophy, as in Dr. Jacoby's case.

DR. ALEXANDER B. JOHNSON read a paper describing

A CASE OF NEURALGIA OF THE GREAT OCCIPITAL NERVE, WITH SYMPTOMS OF A DESTRUCTIVE LESION OF THE CERVICAL SYMPATHETIC.

The patient was a man sixty years old, married, a railroad conductor by occupation. Denies venereal disease; no alcoholic habit. Had malaria thirty years ago. No distinct history of rheumatism. No signs of organic disease. Over the chest and back he has several old, white, depressed scars, which he states are the result of abscesses he had many years ago, and that they were a long time in healing. The patient presented himself on November 1, 1893, complaining of a severe pain in the right side of the head, which made it impossible for him to work. This trouble began three years ago. The pain is of an aching character and occurs in paroxysms. It is referred to a point about two inches behind the lobule of the right ear, and radiates upward and backward to the vertex. There is marked tenderness on pressure over this area. The patient further complained of inability to see well with the right eye, and the upper eyelid on that side droops so far as nearly to cover the pupil when the patient looks straight before him; the lower eyelid is slightly elevated. The right pupil is contracted, smaller than the left, and does not react to light. The

eye is watery, and the right side of the face is redder than the left. There is no paralysis of the face; but the skin and muscles appear less full, and feel flabby in comparison with the left side. The patient was examined by Dr. M. Allen Starr, who located the lesion in the cervical sympathetic, and advised an exploratory operation, as the patient had undergone medical treatment of various kinds without relief.

On November 4, 1893, an incision, three and one-half inches in length, was made along the posterior border of the right sterno-mastoid, beginning just below the mastoid process. The sterno-mastoid muscle and internal jugular vein were drawn forward and the internal carotid artery lifted up. The superior cervical ganglion was found to be included within the sheath of the internal carotid, to which it appeared to be distinctly adherent. The adhesions were divided and the ganglion freed, as well as the cord below to the extent of two inches. No abnormality in appearance could be recognized either in the ganglion or cord, and the wound was closed. The neuralgic pains and the tenderness of the scalp disappeared at once after the operation. The lachrymation and flushing of the face ceased. The pupil on the right side reacted slightly to light and became a little larger, and the right upper eyelid drooped so little that it was scarcely noticeable, and did not at all interfere with vision. At the end of six weeks, however, all the symptoms had returned; and at the present time the patient finds himself in no way improved.

In closing his paper, Dr. Johnson said that while the symptoms in this case were fairly typical of paralysis of, or a destructive lesion of the cervical sympathetic, it is possible that they were due to a lesion of a destructive character situated in the spinal cord, the exact location of which it is at present impossible to determine. He was unable to explain the immediate temporary benefit of the operation in this case, excepting that it was the result of a powerful peripheral impression.

DR. WILLIAM M. LESZYNSKY referred to a case which he presented some years ago, in which there was hæmorrhage into the cervical portion of the cord, with decided symptoms of involvement of the cervical sympathetic on the same side.

The PRESIDENT said that Krouse (*Zeitschrift für Klinische Medizin*, 1891) reports nine cases of crushing accidents to the spinal cord, involving the lower cervical and upper dorsal segments, in which there were marked symptoms referable to the cervical sympathetic. Regarding the case narrated by Dr. Johnson, Dr. Starr said his own impression was rather against the idea of a cord lesion, on account of the absence of other cord symptoms, although that was not a valid reason for excluding it entirely.

DR. BOOTH presented

A CASE OF HYSTERIA, WITH PECULIAR EPILEPTOID ATTACKS.

The patient was a male, aged twenty-two, jeweller, a native of Germany. During the past two months he has had attacks when he suddenly begins to sing, to slap his knees with his hands (either one or both), and to stamp his feet. The attacks come on without apparent cause, and occur frequently during the day and occasionally at night. Each attack lasts only a few seconds, and ends with a screech. Patient does not lose consciousness. When he was eight years old

he had similar attacks, extending over a period of nine months: again, three years ago, he had them for a period of about one year. At that time he went under treatment at Strasburg, Germany, but received no benefit. The attacks ceased of themselves. Patient does not smoke; drinks moderately; practised masturbation to some extent when he was younger, and continued it for three years. Family history negative. Never had a blow or fall. Denies venereal disease.

ELECTRICAL REACTIONS AND THEIR VALUE IN DIAGNOSIS AND PROGNOSIS.

The PRESIDENT stated that the subject of electrical reactions, and their value in diagnosis and prognosis, which had been taken up at the last meeting, was such an important one that it had been decided to continue it at this time.

DR. FREDERICK PETERSON said that in the main he agreed with the previous speakers regarding the reaction of degeneration, and with the conclusions recently published by Remak, in particular. We have found that both nerves and muscles may respond to both the faradic and galvanic currents, and yet degeneration may exist. With the galvanic current, polar changes are inconstant; CCC may be greater than AnCC. In normal muscles we occasionally find, on the other hand, that AnCC may be greater than CCC. There is one sign that may be considered as always present where there is degeneration in the spino-muscular portion of the motor tract, and that is, the sluggish, vermicular contraction of the muscle. Furthermore, in the great majority of cases of degenerative lesions in the anterior horns or peripheral nerves, the faradic reactions are diminished or lost. Dr. Peterson felt that not sufficient stress had been laid upon the actual value of electro-diagnosis in distinguishing cerebral palsies from the degenerative cases. He was convinced that most neurologists found it of the same value as heretofore, though we had modified our opinions as to the manifestations.

One of the speakers at the last meeting called attention to the occasional occurrence of atrophy with degenerative reactions in cerebral palsies, as cited in two cases by Eisenlohr some years ago. It was interesting to know that Eisenlohr had recently made autopsies in both of these cases, and found degeneration in the peripheral nerves. Other observers have found atrophic changes in the ganglion cells of the anterior horns in cases of hemiplegia with muscular atrophy. There is no evidence in those rare instances in which muscular atrophy accompanies cerebral palsy that the trophic change is produced by an affection of the trophic centres in the brain. On the contrary, all the evidence at hand shows that the atrophy depends upon degenerative lesions in the spino-muscular portion of the motor tract. The value of the electrical examination remains therefore as before.

The electric reactions are certainly of great value in the distinction of the primary muscular dystrophies from progressive spinal atrophies.

DR. J. F. TERRIBERRY continued the discussion. He confined his remarks to the value of electrical reactions, as regards diagnosis and prognosis, in paralysis of the facial nerve, and gave the following conclusions, which he had deducted from an analysis of twenty-four such cases coming under his observation:

(1) That we have in electricity an agent of the

highest value as an aid to diagnosis in paretic troubles of the seventh nerve.

(2) That the value of electricity as an aid to prognosis in facial paralysis is comparatively slight. Less than one-half the cases reported could be prognosticated, and even those with considerable hesitation.

(3) That those cases in which the degree of paralysis is slight are the ones of which we can speak with most confidence by the aid of electricity.

(4) That it is impossible to foretell the issue of severe cases by means of the electrical examination.

(5) That the teachings of Erb respecting the diagnosis and prognosis of the lesions of the motor peripheral nerves by means of electricity are the best at our command, although very imperfect.

DR. WILLIAM J. MORTON sent a communication on the subject of electrical reactions, which was read by the Secretary. He stated that in case of degeneration of the nerve, the faradic and galvanic excitability is diminished or lost, while in case of degeneration of the muscle the faradic excitability is lost, but there is an exaggeration of the galvanic excitability and an inversion of its normal polar action. This abnormal reaction of an abnormal muscle was, indeed, a most brilliant discovery by Erb, but it has always seemed to him that an over-refinement of diagnostic and prognostic significance has been attached to it. As regards diagnosis, the electrical reaction is often the only means of deciding that a given nerve or muscle is in process of degeneration. In traumatic neuritis, in multiple neuritis, in the sciatic, facial and many other neurites, in the dystrophies and spinal lesions due to affection of the nerve cells of the anterior cornu, it is certainly a great satisfaction to feel sure that the degenerative process exists, and this satisfaction is easily acquired by aid of the electric reactions. He did not, however, consider the reactions of much value in making a differential diagnosis between one and another of the above affections, or between a multiple and migrating neuritis, or between sub-acute or chronic anterior poliomyelitis and a progressive muscular atrophy, or lastly, between a cerebral and spinal lesion. As regards the prognostic value of electrical reactions, Dr. Morton believed that overconfidence is placed in the deductions to be drawn from "the complete" and the "incomplete reaction of degeneration." In its complete form, as we sometimes see it in grave facial paralysis and in infantile spinal paralysis, our prognosis is unmistakably bad and fairly exact. It is in the incomplete reaction of degeneration that we are often proven to be mistaken if we indulge in a too exact prognosis. In cases where the electrical reactions of both nerve and muscle have been completely lost, he has known the muscle to regain some part of its former volume and the normal electrical reactions to return by means of long-continued local treatment by aid of sparks from an influence machine. He considers that the earliest sign of reaction of degeneration is the failure of a muscle to respond to a spark which will set a corresponding normal muscle into contraction.

DR. LESZINSKY said that in making the differential diagnosis between peripheral and cerebral lesions in cases of facial paralysis, the quantitative changes should be taken into consideration: in the peripheral cases there is a quantitative diminution, while in the cerebral cases there is a quantitative increase. In paretic conditions he still relies on electricity, both as regards diagnosis and prognosis. There are cases in

which we make mistakes, but in the vast majority of instances the laws laid down by Erb are correct.

DR. B. SACHS said that if the discussion of this subject at the last meeting had a nihilistic tendency, it was due to the fact that it was treated from the neurologist's point of view, and the speakers were attempting to make out in what way the current would be of value in refinements of diagnosis. He expressed the view that all of us still recognize the vast importance of electricity in the differential diagnosis between cerebral and peripheral cases, or cerebral and spinal cases, and also its great value in functional cases.

DR. E. D. FISHER said that in the main he agreed with the statements made by the previous speakers. In certain diseases, such as dystrophies, chronic anterior poliomyelitis and progressive muscular atrophy, the electrical reactions are of great value. It is true that in the dystrophies we do not get an absolute loss of the faradic response until very late in the disease; with marked atrophy we may still get a response to the faradic current wherever the fibres remain. As regards the differential diagnosis between cases of progressive muscular atrophy and chronic poliomyelitis, in the former we do not, as a rule, get a complete reaction of degeneration — we may get a partial one — while in the latter we are very apt to get complete reaction of degeneration. In differentiating between cerebral and spinal lesions, electricity is of value, although not always essential.

Recent Literature.

Hospitals, Dispensaries and Nursing. Papers and Discussions in the International Congress of Charities, Correction and Philanthropy, Section III, Chicago, June 12 to 17, 1893. Edited by JOHN S. BILLINGS, M.D. and HENRY M. HURD, M.D. Baltimore: The Johns Hopkins Press. London: The Scientific Press (limited). 1894.

The seven hundred and ten pages of this report contain seventy-five papers, with the discussions on them, so condensed as to make the volume a necessary reference-book on the subjects to which it pertains, and so full of matters of vital interest on all questions connected with the care of the sick that it can be read with profit by every one who wishes to keep informed on modern social science. It should be studied by physicians, and hospital officers and visitors engaged in solving the difficult problems discussed therein. We cannot enumerate by title, with our limited space, the many excellent essays which were read; nor can we, as we would like, call attention in detail to the able treatment of the several topics of argument and debate.

The admirable papers on the function and duties of the modern hospital by Dr. Billings and Dr. Cowles are fully supplemented by thirty-five others covering all points of hospital administration, including the education of physicians and surgeons and training schools for nurses. The greatest advances in the last two decades have naturally been in the way of hygiene, cleanliness in its broadest sense, in development of the system of training highly-qualified nurses, and in a more general use of cottage hospitals in the smaller cities and towns. The next movement must lie in the more intelligent control of infectious diseases by abol-

ishing the "pest-house" and by the construction of isolation hospitals for scarlet fever and diphtheria particularly, of which there are so few in this country. Dr. Thorne Thorne had hardly made the remark that a small-pox hospital should not be within a mile of an inhabited house, as quoted by Dr. Rowe, before more recent researches showed such over-caution to be only consistent with the pest-house idea; while Dr. Davis regards a furnace for garbage, rooms for disinfection by superheated steam and a crematory for the dead quite essential within the grounds of every hospital for infectious diseases.

The one hundred and eighty-six pages given to the consideration of nursing of the sick will amply repay a careful reading.

Dr. Field's description of the reception pavilion for the insane at Bellevue Hospital, with his appeal for the establishment of similar detention hospitals for deciding questions of insanity, and the proper treatment of each person examined in them, in every large city of the United States, and Miss May's six pages on nursing of the insane, comprise all of the volume which is devoted to that important branch of hospital care of the sick. The search-light that has been so well directed to the general hospitals has not yet fully reached the hospitals for the insane, although the advances there, too, have been great.

Medical Jurisprudence, Forensic Medicine and Toxicology. By R. A. WITTHAUS, A.M., M.D., Professor of Chemistry, Physics and Hygiene in the University of the City of New York, etc., and TRACY C. BECKER, A.B., LL.B., Counsellor-at-Law and Professor of Criminal Law and Medical Jurisprudence in the University of Buffalo. With the aid of numerous collaborators. In four volumes. Vol. I. New York: William Wood & Co. 1894.

The obvious intention of the projectors of this extensive work has been to collect in one publication all matters concerning which law and medicine have a hyphenated interest through their mutual relations one with the other, embracing all topics which usage and propriety designate as medico-legal. And it is a pleasure to state at once that if the standard of excellence illustrated in this initial volume is maintained in the three volumes to follow, the two professions of law and medicine will have at their disposal an encyclopædic work of the highest character. The critical reader finds much to praise and little to censure in the plan and execution of so much of the treatise as the present volume exhibits. As is usually the case with a book of composite authorship, there is some inequality in the various chapters; a few appear to have been written hastily and under stress of a pressing requisition for material to be supplied before a stated time, but nearly all the contributions show care, study and finish. Taken as a whole, this volume represents wide research, judicial fairness and freedom from dogmatic self-assertion. The announced list of contributors leads us to anticipate a continuation of these characteristics in the remaining volumes and to declare that as a comprehensive reference-book relative to all medico-legal subjects, this will stand without a peer.

The title of the work offers a novelty in nomenclature. It has been customary to regard Medical Jurisprudence, Forensic Medicine and Legal Medicine as interchangeable and synonymous terms, and this custom still prevails. But it is explained in the introduc-

tion to this volume that there is a real difference which should be recognized, that Medical Jurisprudence treats of "medical law" and that Forensic Medicine deals with "the application of medical, surgical or obstetrical knowledge to the purposes of legal trials." We cannot avoid thinking that this differentiation is arbitrary and unnecessary. That its adoption would be difficult among medico-legal writers and students is well illustrated by the fact that it is not uniformly respected in this volume or, indeed, by the editor himself in the later pages of his introduction.

But the distinction above mentioned offers a convenient opportunity for a broad classification of legal and medical topics in the body of the book. Under the caption of Medical Jurisprudence, several able legal writers have contributed chapters which set forth the legal principles, the judicial decisions and the statutory regulations which govern and control medical practice. The legal rights and duties of medical men in the care of the sick, in the court-room, in the autopsy-room and wherever else they exercise their professional knowledge, are fully and satisfactorily defined. It is interesting to note, in passing, that in the admirable digest of the laws governing the practice of medicine, Massachusetts and New Hampshire are designated as the only States which are without special statutes designed to protect the public from quackery.

In that portion of the book devoted to medical rather than legal themes, are chapters on medico-legal autopsies, personal identity, wounds, death by heat, cold, electricity, hanging, strangling, suffocation, drowning, and starvation. All these subjects are elaborately treated and some of them, like the Medico-Legal Relations of Electricity, for example, have special value because of the contemporaneous interest in the topic and the thoroughness of the author's method in discussing it. The entire volume shows a manifest purpose on the part of its contributors to present whatever they have found to be of medico-legal utility in the latest advances in medical science and all concerned in the preparation of the work, editors, collaborators and publishers, can be congratulated cordially upon the genuine success which has marked their endeavor.

The Principles and Practice of Surgery. By JOHN ASHURST, JR., M.D., Barton Professor of Surgery and Professor of Clinical Surgery in the University of Pennsylvania; Surgeon to the Pennsylvania Hospital; Senior Surgeon to the University Hospital and to the Children's Hospital; Consulting Surgeon to the Woman's Hospital, to St. Christopher's Hospital, etc. Sixth Edition, enlarged and thoroughly revised. Philadelphia: Lea Brothers & Co. 1893.

This is the sixth edition of a work which has been very popular. The author has endeavored to incorporate many of the more important recent observations in surgical science. "An entirely new chapter has been introduced, on Surgical Bacteriology," by Prof. Charles B. Nancrede of the University of Michigan. The specialties on the eye and ear have been scrutinized and revised by colleagues of the author.

The author "ventures to express a hope that in its present form, his volume, though necessarily compendious in its mode of dealing with different subjects, may be considered as affording a satisfactory representation of modern surgery." The work is one of those few works which have survived the advent of modern

methods; and while much of value is retained which existed before antiseptics, yet a strenuous effort has been made to introduce the valuable parts of modern methods. In this we do not believe the author has fully succeeded. The book is condensed, well written, and intended to cover the whole field of surgery; but we cannot help believing that it would be improved by omitting the parts on special surgery. As a matter of example, the presentation of the subject of diseases of the joints and of orthopædic surgery is lamentably behind the times. In this work Americans stand well towards the head; and the apparatus which is represented and the methods spoken of are those of the English school of orthopædics of thirty odd years ago.

The book has a distinct value in that the author retains many of the points and hints of treatment with which the older books were filled; but, as a whole, it cannot be considered a work representing modern surgery.

Infectious Diseases, Notification and Prevention. By LOUIS C. PARKES, M.D., London, D.P.H. Pp. 185. London: H. K. Lewis. 1894.

This compact and handy manual contains all the existing English laws upon the sanitary management and control of infectious diseases. Part I presents these laws, together with full explanatory notes by the author. Part II contains much useful information in a condensed form, upon various practical subjects relating to the diagnosis and the prevention of infectious diseases. The special topics treated are Incubation Periods, Quarantine, Infective Periods, Sources of Infection, Infectious Outbreaks in Schools, Isolation at Home, Disinfection, the Relation of the Medical Officer of Health to the Medical Practitioners of his District.

The clear and intelligent arrangement of the descriptive matter under the different infectious diseases will commend the book to every practical sanitarian. The tables were collated from the report of a committee appointed by the Clinical Society of London to investigate the periods of incubation and contagiousness of certain infectious diseases.

This extremely practical hand-book should be in the hands of every American health-officer, and will be found very useful to the general practitioner.

Diseases of the Eye. A Practical Treatise for Students of Ophthalmology. By GEORGE A. BERRY, M.B., F.R.C.S. Ed., Ophthalmic Surgeon, Edinburgh Royal Infirmary, etc. Second edition, revised and enlarged, with colored illustrations from original drawings. Pp. 727. Philadelphia: Lea Brothers & Co. 1893.

This book is emphatically what its sub-title states it to be, "a practical treatise for students of ophthalmology." It is comprehensive and concisely written, and a judicious proportion has been observed in the allotment of space to the different subjects. The illustrations which are incorporated in the text are, in the main, colored prints from original drawings. Those representing the external diseases of the eye are, with a few exceptions, satisfactory, and much superior to any we remember to have seen in students' text-books. The plates representing diseases of the fundus are even better, and are beautiful specimens both of drawing and reproduction.

With regard to the much-discussed question of whether to do an iridectomy or not in cataract operations, our author has but one opinion, and that is, that

a small iridectomy should always be done, and dismisses the whole subject as follows: "The only disadvantages (of an iridectomy) are, therefore, a wound in the iris and a less beautiful pupil. . . . The cosmetic advantages of a round, active pupil, when it can be obtained, are altogether trifling in those elderly individuals who are the usual subjects of cataract extraction. The game is, in fact, not worth the candle."

In regard to the after-treatment of cataract, he places his bandage only over the operated eye, as, in his opinion, the pain caused by moving the eyes about before the anterior chamber is re-established is sufficient to compel the patient to refrain from using his eyes. He believes that the patient should be kept in bed "at least two days," and the room in semi-darkness.

The subject of treatment throughout the book is clearly and conservatively written. In the treatment of trachoma, while excision of the retrotarsal fold is described, no mention is made of expression of the follicles, as is so commonly done in America; and we were surprised to note that no mention of antiseptic collyria or ointments is made.

Upon the whole, however, the book is an eminently satisfactory text-book.

A Practical Treatise on Medical Diagnosis. For Students and Physicians. By JOHN H. MUSSER, M.D., Assistant Professor of Clinical Medicine in the University of Pennsylvania, Philadelphia; President of the Pathological Society of Philadelphia, etc. Octavo, 873 pages, 162 engravings and 2 colored plates. Philadelphia: Lea Brothers & Co. 1894.

The number of treatises on the Theory and Practice of Medicine by American authors is rapidly increasing. The one before us by Dr. Musser on Medical Diagnosis is in many respects a very good book. Its arrangement is simple. It is divided into two parts: Part I is devoted to General Diagnosis, and consists of chapters on General Observations; the Data obtained by Inquiry; the Data obtained by Observation; Bacteriological Diagnosis; the Examinations of Exudations, Transudations, Cystic Fluids; the Morbid Processes and their Symptomatology. Part II is devoted to Special Diagnosis. The first seven chapters deal with Anatomical or Regional Diagnoses; chapter eight deals with Diseases of the Blood and Ductless Glands; chapter nine with Constitutional Diseases; chapter ten with the Infectious Diseases; chapter eleven with Diseases of the Nervous System.

The book emphasizes the extent to which instruments of precision and laboratory processes have superseded, or at least simplified, the older and slower methods of minute observation and elaborate systems of differential diagnosis. But we do not wish to indicate by this statement that the author underrates the importance of careful inquiry and observation. The pages merely show plainly, what every hospital physician or teacher of long experience realizes daily more and more, that the last ten years have revolutionized in many ways the means, the methods and the details of diagnosis. This is nowhere more apparent than in diseases of the blood, than in the information to be had from microscopical examinations of the blood and exudations. A differential diagnosis of typhoid fever, or the stage of a pneumonia, may be determined in the laboratory; and even the stethoscope and the thermometer are being shorn of some of their glory.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, APRIL 19, 1894.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE DOCTOR IN FICTION.

It is well worth the contemplation of an idle hour to consider the position held by the medical man in the fiction which, in the reading world of to-day, plays so important a part. We have all of us seen the doctor appear in the drama — the apostle of science, the wise counsellor to the interesting invalid, the good elderly walking-man of the piece; and we have all no doubt wondered whether we individually appear to the world at large, such mild inanities. In fact, it must be admitted that the doctor has hitherto not been accorded a very prominent place in light literature, especially in English literature, when compared to that granted to the clergyman or lawyer. Perhaps the reason for this is that English society, which the novel tries to depict, still lingers in the miasma of feudalism, and the doctor whose career leads neither to place nor power has no proper position in a society which grants precedence to title inherited by primogeniture or to the dignity of landed estates.

To Richardson, Fielding, Addison, Goldsmith and Sterne, the doctor had little that was picturesque or interesting; and the earlier great writers, Chaucer, Spenser, Milton, of course, found little use for the leech or the barber-surgeon. Shakespeare, who mirrored all life, used the doctor only occasionally as in a minor part, finding him of no more importance than the apothecary, or the wise woman who was consulted in regard to Falstaff's health.

Now and then, in later literature, a mention is to be found of a medical man, as when Cowley, in poetic frenzy, compares Dr. Scarborough cutting for stone to Moses striking the rock. Mr. Samuel Warren, as is well known, a physician of repute and note of the past generation, has written at least one novel "£10,000 a Year" which has outlived his time, and has vitality to-day. But these are exceptions. The great novelists, Scott, Thackeray and Dickens, found little employment for doctors in their works, although the former must have lived in an atmosphere in Edinburgh

redolent with the fame of surgeons. Thackeray dedicated one of his novels to his physician who had "brought him through" a severe illness; but to him doctors were apt to be socially off color, and it is put to Pendennis's credit that he did not deny the fact that his father drove a gig and visited patients. Dickens exercised some of his humor upon doctors, making the doings of the young "Sawbones" amusement for a generation. Trollope, considering how much he wrote and that, too, in the low tone of mild realism, with sober tints well suited to the sombre character of the doctor, made but little of the physician as compared with the clergyman or lawyer.

Charlotte Brontë introduces a physician prominently in "Villette." George Eliot, however, makes a great exception in "Middlemarch"; her character of Lydgate — one of her most interesting creations — illustrates well the aspirations of a young and ambitious physician, and the pitfalls and easy path to failure. Miss Evans always worked carefully and evidently in thorough sympathy with medical life; and in her description of Lydgate's treating a case of delirium tremens, the authoress gave evidence of her thorough study of the subject, for she makes her medical hero anxious to try the treatment advocated by Dr. John Ware, of Boston, in a monograph which, if known in the medical thinking world of that day, is almost forgotten now, even in his native city.

In France, doctors seem to have always been in popular favor, even in the days when their absurdities were such as to be made famous by the wit of Molière. Their prominence in the community inspired the critical genius of the dramatist; and the medical profession of succeeding generations are his debtors for the immortal life he gave to those errors and follies which the successful practitioner, to-day as in the seventeenth century, should seek to avoid. But of all writers of fiction Honoré de Balzac, the greatest of the novelists of the modern school, as well as the founder of that school, was most in sympathy with the physician. He was fond of introducing in his "Comédie Humaine" the mythical Bianchon, the enthusiastic student in the École de Médecine, laboring hard at the cliniques and laboratories, while his contemporary, Rastignac, was seeking to advance his fortunes by intrigue in the salons and boudoirs of the Faubourg St. Germain or at the Tuileries. Later, Bianchon becomes the famous surgeon, who lives a successful life devoted to professional work, while fortunes and intrigues have fallen in the foolish worldly game of personal advancement. To Balzac's mind evidently the physician lived a life of calm content in his own work; and in his devotion to that science which was above the folly of courts, outlived revolution and dynasties and fulfilled a career high in its purpose and broad in its scope, with the ideal enthusiasm of a religious devotee. In the "Médecin en Campagne," Balzac has presented not only the highest type of a physician in fiction, but has given to posterity a figure to be respected by all. A strong man is portrayed whose life was blasted in early

youth by the consequences of youthful indiscretion, but who rose from the chastisement to the noble work of elevating a community, not only helping the sick, but teaching by example and by personal influence the wisdom of a sane life. Beloved and respected by all, not a self-seeker, but arbitrary in enforcing what was best for the health of his patients and of the community, broad, far-seeing, strong and self-sacrificing, M. de Benassis will live to remind the reading world of the possibilities in a medical career — possibilities which the annals of the medical biographies in every community show not to be simply figments of the brain of a romancer.

Recent French literature has produced nothing equal to Balzac, and no medical figure equal to his "Country Doctor"; but one of the most dramatic scenes in that best of recent novels, "*Les Rois en Exile*," is laid in a physician's office, where the last of one of the royal families of Europe is brought *incognito* to seek advice, bearing the curse of a malady inherited from a father who thought more of the Jardin Mabille than his lost throne; the queen-mother sits in the waiting-room of a celebrated surgeon with peasants and tradespeople, and, when her turn comes, hears from the oracle of that science which knows no kings or royalty, that her son's blood, the noblest blood in Europe, is tainted.

In America, the doctor has always been a man of influence, and we should expect he would receive due attention in literature. The American novel, however, is of recent growth; for Cooper worked on European models, his matter, except in descriptions of scenery, was not American, or at best only what Cooper thought was American. Hawthorne, our great romancer, did not study real life in the commonplace world around him; he was a morbid psychologist, a mental pathologist with wonderful beauty of language. He has, however, left us a sketch of a medical recluse in "*Dr. Grimshaw*," which shows the handiwork of a master even in its outline. An excellent physician appears in "*Elsie Venner*," alive with the intelligence of the author, our honored Professor Emeritus, the Autocrat of the Breakfast Table. Our working American novelists, James, Howells and Cable, have all tried their hands on doctors. Mr. James, who is essentially the novelist of good manners, and who writes from the point of view of a man of the world, evidently recognizes the fact that the doctor in America may perfectly well be a man of good society, which appears not to be the case in London. Still Mr. James's attempts at creating doctors have not been successful; they are doctors only by title, without any medical vitality. Mr. Howells has done better with Dr. Mulbridge in "*Dr. Breen's Practice*"; but to our minds, Dr. Sevier, the central figure in one of Mr. Cable's best stories, is a creation of much more than passing excellence. The force, the quick and broad sympathy, the impatience of shams, the *sava indignatio* at the silliness and imbecility of the average of mankind, are not only well depicted, but true to the

type of physician. The creole is represented as being a man of large practice, of a lonely life, of much sorrow, and with the acuteness to see that his sorrow was earned by violation of the laws of health and must be manfully borne. Miss Jewett has produced a valuable study with an abundance of local color, in her "Country Doctor"; and Judge Grant, in his "*Reflections of a Married Man*," intimates that in American society, even among "smart" people, the presence of a few distinguished specialists is desirable to complete the social gathering. In this author's last book, "*The Opinions of a Philosopher*," there is a "snap" pen-picture of Miss Cora Jacket, M.D., "a regular practitioner in the allopathic line," and Winona, the hero's pretty daughter, becomes a practising Christian Scientist. Crawford, in his last story, "*Katherine Lauderdale*," the scene of which is laid in New York, gives us a pleasant glimpse, in the person of Dr. Routh, of the general practitioner who is the family friend and adviser, whose aid and counsel are sought in a delicate and perplexing emergency, and who saves the honor of his patient by a letter to the newspapers, as he saves his health by dietetic prescriptions.

The female physician has already been served up in several different forms; but she will probably appear again, as the subject is one which is not yet exhausted.

A fact to be noted is the *début* in the world of fiction of our celebrated specialists, Dr. Weir Mitchell and Dr. Hammond. The latter, in addition to those novels already written, promises to write two every year, thinking that physicians have an inexhaustible fund of knowledge of human nature, dealing as they do in humanity as their staple commodity and sampling it in different grades, for the stamp of different treatment. There seems to be no reason why physicians should not write novels, now that novel writing is becoming a pastime, like bicycling or base-ball or tennis. Of course, the professionals are the masters, but the amateurs may make a good deal of fame for themselves. We shall have all the neurologists and alienists illustrating their views of life by some horrid example held up to the terrified public. It affords an amusing relaxation, and will do but little harm. In fact, it must steady the nerves harassed by care; at least, Lord Beaconsfield found it so, and consoled himself when vanquished by publishing "*Endymion*." Why should not physicians also partake of this new anodyne, if they can find the time after their severer labors?

THE DISCUSSION ON THE PARASITISM OF CANCER AT THE ELEVENTH INTERNATIONAL CONGRESS OF MEDICAL SCIENCES.

ONE of the most interesting discussions at the Eleventh International Congress of Medicine, held recently in Rome, was that on the parasitism of cancer, in which Pio-Foa, Cornil, Duplay, Cazin, Ruffer and others took part. It is known that Pio-Foa, referee, is one of the most strenuous advocates of the

parasitic or infectious nature of malignant neoplasms. The "parasites" are certain protoplasmic bodies — when fully developed enclosed in a distinct capsule — contained in the cancer cell, sometimes within, sometimes without, the nucleus, and resembling the spores of protozoa. Soudakevitch, Ruffer, Walker, Clarke and others have described such elements, which they regard as sporozoa, bearing a resemblance to the hæmatozoa of malarial fever. These parasites are common to almost all cancers of glandular origin. The peripheral portions of the neoplasm contain parasites of small dimensions, while at some depth from the surface are found large sporocysts.

In parts which are rich with parasites, karyokinesis is wanting or is little marked. On the other hand, in parts where the proliferation of the tissues is active, the parasites are wanting, or are few in number. This shows that they live, but in tissues whose vitality is low. Arguments were advanced to prove that these strange bodies were not degenerate cell nuclei. Pio-Foa claims to have followed all the stages of development of these parasites from a little corpuscle the size of a nucleolus, to the sporocyst as large as a full-sized cell nucleus. Thus far, it has been impossible to obtain cultures of these parasites. Cancer is not inoculable by grafting, except in individuals of the same animal species.

Though parasites may not be found in all tumors manifestly cancerous, they doubtless exist there in the state of spores difficult to distinguish from nuclei. These spores "infect other cells, and are transported with them into the secondary nodules where the parasite develops anew, and where it infects other histological elements. The cells containing the parasites eventually die and disintegrate, while the surrounding cells undergo a process of active proliferation.

Professor Cornil, of Paris, declares himself as yet far from convinced that the forms which Foa and others described were parasites. We find in cancer a great number of modifications of the form of cells and of nuclei which might easily be taken for parasites. The nuclei of cancerous cells divide sometimes into two, sometimes into three, four or more secondary nuclei, and these divisions end in the production of two or more cells, each containing a nucleus, or in the production of several nuclei inhabiting the protoplasm of several cells.

The nuclei of the cells undergoing division are small, rich in chromatic material, but they soon become fimbriated on their borders, knobbed, with predominance of liquid in their interior; they may become completely achromatic. They will then present the most varied shapes, from crescents to double sacs, crowns, little knobby or spherical masses (secondary nuclei) containing little coloring substance. These transformed nuclei sometimes present an oedematous appearance (hydropic nuclei).

Much of Cornil's description we omit as being too long and too technical. The result of close observation with staining methods has convinced him that

Foa's parasites are only metamorphosed nuclei, a product of morbid karyokinesis. According to Cornil, there are found also in cancer degenerated cells whose protoplasm stains red, and which contain in place of nuclei granules, filaments, or masses of nuclein representing the different forms of indirect division, without the occurrence of achromatic filaments or of clear space around the divided nuclein. These are cell degenerations arrested in one of the phases of indirect division of the nuclei. Cornil remarked that even migrating leucocytes interposed between cancer cells had been mistaken for parasites, especially when they had retrograded and had broken up into fragments of nuclein.

Duplay and Cazin, of Paris, stated that their researches on the structure of the constituent elements of epithelial cancers had led them to the same conclusions as those of Professor Cornil. The coccidia of Foa and others are only forms of cell degeneration, products of "indirect division," and have no parasitic character.

Ruffer, of London, spoke in support of the claims of Pio-Foa, corroborating his conclusions, while Morpurgo, of Turin, as stoutly confirmed the position of Cornil, Duplay and Cazin. So that the parasitic, and in particular the psorospermic origin of cancer, may be considered as still *sub-judice*. We have to oppose to the weight of Professor Cornil's assurance that the "organisms" are simply altered histological elements, the decided opinion of Metchnikoff and Sims Woodhead that they are "undoubted coccidia." Admitting the nature of these bodies to be parasitic, it might be claimed that they are only accompaniments of malignant growths, not the cause. The conditions of their growth and development, according to Dr. Sims Woodhead are a lowered condition of the vitality of the epithelial elements in which they make their habitat. Finding a suitable soil, they multiply, secrete their toxins, and by their irritant action on the parts which they invade, resemble certain well-known pathogenic microbes, especially Koch's bacillus, in the degenerative processes and products which they entail. One extremely weak link in the chain of evidence, as Dr. Woodhead admits, is that hitherto inoculation experiments with cancerous material have very rarely been successful in producing any cancerous reaction.

VITAL STATISTICS OF ENGLAND FOR 1893.

THE Registrar-General of England publishes an advance-sheet or abstract of the vital statistics of England and Wales at a much earlier date than that of the annual report, which is rarely published till a year later. From this advance-sheet, just received, we learn that he estimates the population as 29,731,100 at the middle of the year 1893, this being an increase of 728,575 over the number of the population as taken by the Decennial Census of April 6, 1891.

The marriages in 1893 were 218,251; the births were 914,189; and the deaths were 569,923. These

figures give a marriage-rate of 7.34 per 1,000 of the estimated population (14.68 persons married), a birth-rate of 30.75, and a death-rate of 19.17. Estimating the excess of females over males to have maintained the same rate of increase as for the ten-year period 1882-1891, the death-rate of males was 20.27, and that of females 18.14 per 1,000, or as 1,000 females to 1,117 males in equal numbers living.

The figures for London were as follows (1893): marriage-rate, 8.58 (persons married, 17.17); birth-rate, 30.86; death-rate, 20.83.

The healthy excess of the birth-rate over the death-rate in England, amounting to nearly 50 per cent. (48.1), presents a strong contrast with the vital statistics of France, which are as follows for the years 1891 and 1892:

	1891	1892
Marriages	285,456	290,319
Births	866,377	865,247
Deaths	876,882	875,888
Excess of deaths over births	10,505	20,041
Marriage-rate	7.4	7.3
(Persons married)	14.8	15.0
Birth-rate	22.5	22.3
Death-rate	22.8	22.7

MEDICAL NOTES.

SMALL-POX AT SING SING.—Three new cases of small-pox occurred this week among the men working in the rag department of Sing Sing Prison.

UNITED STATES QUARANTINE PHYSICIANS FOR EUROPEAN PORTS.—The detail of surgeons from the Marine-Hospital Service for duty at European ports during the coming summer has been made. Three of the appointments are the same as last year: Dr. Woodward to Hamburg, Dr. Stimpson to Rotterdam, and Dr. Brown to Havre. The other appointments are as follows: Dr. Magruder to Naples, Dr. Perry to Genoa, Dr. Vaughn to Bremen, Dr. Carmichar to Antwerp.

BOSTON AND NEW ENGLAND.

BOSTON CITY HOSPITAL HOUSE-OFFICERS.—The rules of the Boston City Hospital have been changed so as to open the competitive examinations for positions as house-officers to graduates in medicine of not over three years' standing.

ACUTE INFECTIOUS DISEASES IN BOSTON.—During the six days ending at noon, April 17, 1894, there were reported to the Board of Health of Boston the following numbers of cases of acute infectious disease: diphtheria 28, scarlet fever 37, measles 11, typhoid fever 15, small-pox 1 (with 1 death). There are now 6 patients in the hospital. During the same period 8 cases of small-pox were reported to the State Board of Health, 3 from Chicopee and 5 from Holyoke.

THE BOSTON SCHOOL COMMITTEE AND VACCINATION.—At a recent meeting of the Boston School Committee the question of enforcing the present statute requiring vaccination of pupils in the public schools was brought to a vote, and was decided most properly in the affirmative. Six members of the board voted to

do away with the regulation. They were Miss Hastings, Miss Pingree and Messrs. Blanchard, Estes, Winship and Wise. A most excellent example, surely, to set the young aspirant for citizenship, to disregard the law at the very threshold of the public school!! "As the twig is bent" —

DIPHTHERIA AT WAREHAM.—So many cases of diphtheria have occurred during the last week at Wareham, Mass., that the public schools have been closed.

THE SMALL-POX AT CHICOPEE.—The number of cases of small-pox at Chicopee has become so large that the Board of Health has decided to build a quarantine hospital, as first proposed in the winter, but rejected on account of expense.

THE STATE SUPERVISION OF VACCINE FARMS.—The Committee on Public Health of the Massachusetts Legislature, in response to the hearing at which committees from the Norfolk and Suffolk District Societies presented petitions with the draft of a bill to establish State farms for the production of vaccine virus, has reported, not the desired measure, but a bill to place "all vaccine institutions in the commonwealth under the supervision of the State Board of Health." Such an act, if passed, will make the last state of the matter worse than the present one. The bill confers no defined powers and prescribes no penalties. It establishes a supervision which does not supervise, and private institutions will be the sole gainers, in being able to claim for their products State guarantee, while the public at large will be led to rest in a false security.

THE RHODE ISLAND ANTI-VACCINATION BILL.—The Anti-Vaccination Bill before the Rhode Island Legislature came dangerously near being passed by the House last week. Although a bill carrying such a menace to the public health was under consideration, there was such a disgraceful apathy on the part of the legislators that the House was obliged to sit for four hours with locked doors to compel the attendance of members. After a bitter discussion, the bill was finally lost on the deciding vote of the speaker. That such a proceeding could have occurred in a civilized community in the year 1894 is not a fact to be passed over lightly. If anything marks the true advance of a community towards a higher plane of social enlightenment, it is the attention which such a community pays to questions of public sanitation and hygiene. The average community is not overprotected by proper and sensible statutes regarding public health; but if there is one such, it is beyond question the enforcement of vaccination. To abolish any such regulation is to step back two centuries.

CONDITION OF THE MATHER SCHOOLHOUSE.—The Committee appointed by the Boston School Board to inquire into the sanitary condition of the Mather Schoolhouse, in view of the numerous cases of contagious disease among the pupils during the early winter, has reported as follows: "The Mather Schoolhouse is

an old building, far too small for the number of rooms into which it is divided; the lot is about one-half the size of an ordinary schoolhouse lot. Each class of fifty-six pupils is occupying floor space equal to about two-thirds the area of a modern schoolroom. The windows in the rear of the school building are close to the sanitariums. The windows of the police station, which ventilate the cells, open on the schoolhouse-yard and emit foul odors a few feet from the schoolhouse windows.

THE SIXTY-FIRST YEAR OF THE BOSTON LYING-IN HOSPITAL. — The annual report of the Boston Lying-in Hospital for 1893 shows a continued high record of usefulness. The year just closed is the first completed in the finished new hospital, and the building has proved in every way to be admirably adapted for its purposes. Five hundred and one women were treated in the hospital, an increase of one over 1892. There were 505 children born during the year. In the Out-Patient Department 1,352 women were cared for — an increase of 274. Out of this total of 1,853 patients only 4 died, a mortality of less than one-quarter of one per cent. One woman died in the hospital in convulsions from chronic Bright's disease twenty-eight days after entrance. Among the out-patients two women died of pulmonary embolism and one of eclampsia. In addition to these, three out-patients were sent to the general hospitals suffering from septicæmia: one recovered, one died from mania, and one of old cardiac and pulmonary disease. Certainly such a record is one to be proud of. The work, especially among the out-patients, has increased so much that the number of house-officers has been raised to three — each officer now serving two months as junior in the house, two months as assistant physician to out-patients, and two months as senior house-officer. The house-patients were 206 Americans and 295 foreigners. Three hundred and eight were married, 193 single. The training-school for nurses gave diplomas to fifteen graduates.

NEW YORK.

VACCINATION REQUIRED OF THE CREWS OF NETHERLAND STEAMERS. — Dr. Jenkins, Health Officer of the port, has notified the Netherlands line, two of whose steamships have recently arrived with cases of small-pox on board, that their vessels will not be allowed to enter the port of New York unless their crews have been vaccinated before leaving Rotterdam. He has also notified the United States Consul at Rotterdam that clearances for New York should not be given to the Netherlands line steamships until this provision has been carried out and until disinfection of the persons of all their passengers and seamen has been made.

MORTALITY. — The general health of the city continues unusually good for this season of the year. During the week ending April 14th there were reported 853 deaths, which was 21 less than in the previous week, and represents an annual death-rate of 22.37 per thousand of the estimated population. The cold and

stormy weather had apparently some effect in increasing the mortality from pneumonia, which caused 125 deaths, a larger number than occurred from any other one disease. Diphtheria caused the largest number of deaths among the contagious diseases, 41. The mortality from scarlet fever amounted to 20, and from small-pox, to 7. During the week 1,012 births were reported.

Miscellany.

VACCINATION IN THE JAPANESE NAVY.

The annual report of the health of the Imperial Japanese Navy for the twenty-fifth year of Meiji (1892), just published, gives some interesting details as to the success or failure of over 5,000 cases of vaccination.

Of the vaccinations for the first time, 38 were successful and 65 unsuccessful (36.89 and 63.11 per cent.); of the cases vaccinated for the second time, 220 were successful and 457 failed (32.50 and 67.50 per cent.); of third vaccinations, 404 succeeded and 973 failed (29.34 and 70.66 per cent.); of fourth vaccinations, 386 took and 854 failed (31.13 and 68.87 per cent.); of fifth vaccinations, 195 were successes and 562 failures (25.76 and 74.24 per cent.; of those vaccinated for the sixth time or over, 141 were successful and 498 unsuccessful (22.07 and 77.93 per cent.). In cases in which there was an uncertainty as to scars from small-pox, 119 vaccinations took and 193 failed. In all there were 1,503 successes and 3,602 failures, a percentage of 29.44 and 70.56 respectively.

The ratio of success or failure per hundred cases of vaccination during the period of nine years from 1883 to 1891 was 38.98 and 61.02 for all cases; the ratios for the various classes of first, second, third, etc., vaccination being 58.68 and 41.32, 46.80 and 53.20, 35.57 and 64.43, 32.86 and 67.34, 28.25 and 71.75, 26.83 and 73.17.

This last series particularly shows that while the chance of successful vaccination steadily diminishes with each repetition, namely, from 58 to 26, there is still more than one chance in four that even a sixth vaccination will take — a fact which should emphasize the importance of a general revaccination of persons of all ages at the time of any public need.

TAPPING OF THE LATERAL VENTRICLES.

No longer abashed by the fear of entering the peritoneal cavity the surgical Charmides now seeks to penetrate other sanctuaries — even into the inmost recesses of the brain. Tapping through a fontanelle for hydrocephalus is no new procedure; but it is only within a few years that any technical perfection has been reached in withdrawing fluid from an overdistended cerebral ventricle. Dr. Frank, of Chicago, reports¹ two interesting cases of his own, in which the results obtained were sufficiently marked to justify the operation, although both patients died. One was a case of acute hydrocephalus ventriculi resulting from severe injury to the head with multiple fractures of the base, which were made out post-mortem only. After tre-

¹ Annals of Surgery, April, 1894.

phining, the ventricle was opened by an aspirating needle corresponding to a No. 3 catheter (American scale), and about three ounces of fluid withdrawn. There was considerable relief from the pressure symptoms. The second case was one of idiocy following hydrops ventriculorum due to cerebro-spinal meningitis.

After reviewing the history of this radical though rational procedure and discussing the surgical ease and safety with which it can be done, he draws the following conclusions, which are of interest:

"Trephining and tapping the lateral ventricles —

"(1) For distention of the ventricles from acute, simple or tubercular meningitis, is a therapeutic measure clearly indicated, and other things being equal, promises recovery.

"(2) For effusion of blood into the ventricles from trauma or disease, makes recovery a possibility.

"(3) For abscess, involving the ventricles, is immediately and imperatively demanded.

"(4) For effusion into the ventricles, from brain tumors, may afford relief to symptoms.

"(5) For chronic hydrocephalus, moderate distention of the ventricles, without enlargement of head, may afford relief.

"For chronic hydrocephalus, great distention of ventricles, enlargement of head, will lead to a fatal result."

SURGICAL TREATMENT OF PULMONARY CAVITIES.

THE surgical treatment of pulmonary cavities is a department of therapeutic technique which has much to commend it to careful attention. While experiments upon animals and a few remarkable cases have shown that considerable portions of lung tissue may be removed without serious impairment to health, there has been great hesitancy in applying surgical treatment to cases of pulmonary disease which are properly open to it.

In a paper read before the New York State Medical Association, N. Pendleton Dandridge, M.D., of Cincinnati,¹ gives the following conclusions concerning operative treatment:

(1) A certain number of lung cavities can be successfully dealt with by incision and drainage.

(2) Tubercular cavities in the lower portion of the lungs — if single and superficial, and the general condition of the patient permits — should always be opened. Cavities at the apex should only be opened where free and persistent fetid expectoration is present, and has resisted treatment, and the rest of the lung is not involved.

(3) Abscess, gangrene and hydatid cyst should be opened and drained whenever they can be located.

(4) Closure of the pleura should be present before evacuation of a cavity is attempted.

(5) In cases of pyopneumothorax the fistulous track should be explored, and any cavity freely laid open by the cautery.

(6) Cavities that have been opened are best treated by packing with gauze, preferably iodoform.

(7) The further careful trial of such agents as iodoform, chlorine gas, and chloride of zinc, is desirable to determine as to whether the tubercular infiltration may not be modified by them.

¹ *Annals of Surgery*, February 1, 1894.

(8) It is very desirable, for the further extension of surgical interference in pulmonary cavities, that the means of locating such cavities, and of determining their size, and the exact character of the tissue that overlies them, should be perfected by further study, and for the accomplishment of this the surgeon must look to the physician.

TWO ATTACKS OF TYPHOID FEVER IN THE SAME PERSON.

THE few opportunities for accurate observation of two attacks of typhoid fever in the same patient, especially under similar conditions, make reports of such cases of considerable interest.

Drs. Hand and Patek report¹ such a case from the service of the German Hospital in Philadelphia. The patient, a woman aged nineteen years, entered the hospital March 29, 1893, having been unwell for several weeks, and in bed six days. She had a typical mild attack of typhoid fever, and was discharged in good health five and a half weeks after entrance. On September 21, 1893, she was readmitted. On the ninth day she had a second attack of well-marked typhoid fever. This ran an uncomplicated course, and she was discharged in four weeks. In each attack there was enlarged spleen, gurgling in the right iliac fossa and typical rose-spots. The treatment was the same during each attack: a bath every three hours when the temperature was over 102°. During the first illness she had forty-three baths, and in the second thirty-eight. The temperature reached normal on the same day on each occasion.

THE MUÑIZ COLLECTION OF SKULLS.²

THE nineteen trephined skulls selected from the large collection of over a thousand crania gathered by Señor Manuel Antonio Muñiz, M.D., Surgeon-General of the Peruvian Army, form the largest and most instructive collection of specimens of primitive trephining thus far brought together. They show distinctly three types of operation.

The first is that in which a rectangular button was removed by means of four linear incisions made in parallel pairs intersecting at right angles. The incisions are narrow, v-shaped in cross-section, and gradually increasing in depth from ends to centre, thus indicating that the instrument was a pointed bit of stone or arrow-head held vertically and operated by reciprocal motion. This type of operation is rude and the resulting traumatism is jagged, each incision extending perhaps half an inch beyond the button at each extremity. There is no indication of the purpose of the operation of this type in any case, and nothing to suggest that if the operation was ante-mortem the individual survived.

In the second type of operation the incision was evidently made also by a rudely-pointed instrument, probably of stone, held vertically and moved reciprocally; but as the cutting reached and penetrated the inner table, the locus of incision was moved forward and at the same time the direction of the sawing was changed so as to produce a rudely-curved cut and, when two

¹ *Medical News*, April 14, 1894.

² *Bulletin of the Johns Hopkins Hospital*, vol. v, No. 27.

such incisions were made, an irregularly elliptical button.

The third type of operation was performed largely or wholly by scraping in such manner as to remove the outer table and diploë and reduce the inner table to a feather-edge. Some of the examples suggest that the scraping, which may easily have been effected with stone instruments and gives no indications of the use of metal, represents the final part of an operation begun by the curved incision. The deftness of the operators may be inferred from one specimen in which, although the skull is fully a quarter of an inch thick, the parallel incisions are not more than three-eighths of an inch apart. Several of the skulls show that the patient had survived one or even two trephining only to perish during a later operation.

The collection is of especial value as demonstrating certain points heretofore obscure, and warranting the following conclusions: (1) That the operation was ante-mortem, since five individuals out of the nineteen represented certainly, and two or three more probably, survived one or more operations; and (2) that the trephining was surgical. Two provisional conclusions of importance are also indicated by the collection: (3) that the operation was used in a medical way to relieve a general pathologic condition; and (4) that the operation was, as indicated by the total absence of marks of metallic instruments, anterior in date to the Spanish invasion and thus essentially prehistoric. Two of the crania are to be given to this country, one to the Bureau of American Ethnology and one to the Army Medical Museum.

THERAPEUTIC NOTES.

TO RENDER CASTOR OIL PALATABLE.—An ordinary dose of castor oil may be rendered odorless and tasteless by simply shaking it thoroughly in a flask with warm milk.

TREATMENT OF MEASLES BY EUCALYPTUS INUNCTION.—Dr. C. E. Shelly reports² the use of eucalyptus inunction in a series of cases of measles. The favorable reports of other observers were not confirmed. The total number of cases observed was seventy-three. Of these, five received the treatment by eucalyptus. Inunction was begun directly they came under observation, night and morning for three days, and subsequently once a day for the first week. Eucalyptus emulsion was given internally, some of the fluid was placed in saucers about the room, and when cough was troublesome eucalyptus inhalations were given. The results were not at all favorable. There was unusual drowsiness: "all five patients sleeping almost constantly, being aroused with some difficulty to take their food, and remaining awake only just long enough to consume it." All five had tongues thickly coated with white fur, contrasting markedly with the tongues of others under different treatment. The eruption of the rash was delayed in four of the cases and in all there was a relatively prolonged pyrexia. Convalescence was in all five cases more tardy than usual, and desquamation much more profuse. In general the symptoms "seemed to indicate an undue retention of morbid products, rather than that speedy and complete destruction of the infective poison which the advocates of this treatment claim as one of its special advantages."

² Practitioner, November, 1893.

Correspondence.

THE MASSACHUSETTS HOMŒOPATHIC MEDICAL SOCIETY LUNCHEON.

Boston, April 14, 1894.

MR. EDITOR: The following appears in your number of April 12, 1894: "The programme of the annual meeting of the Massachusetts Homœopathic Medical Society included a luncheon at the State Insane Hospital at Westborough."

I wish to say that the luncheon alluded to was paid for by the Massachusetts Homœopathic Medical Society, and not by the State Insane Hospital at Westborough.

Respectfully yours,

CHARLES R. CODMAN,
Chairman of the Board of Trustees of the
Westborough Insane Hospital.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, APRIL 7, 1894.

Deaths reported 2,547: under five years of age 957; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fever) 382, consumption 328, acute lung diseases 317, diphtheria and croup 147, scarlet fever 60, measles 51, diarrhoeal diseases 28, typhoid fever 26, whooping-cough 20, cerebro-spinal meningitis 15, small-pox 14, erysipelas 9.

From diarrhoeal diseases New York 11, Brooklyn and Milwaukee 4 each, Philadelphia, Washington, Cambridge and Taunton 2 each, Cleveland 1. From typhoid fever Philadelphia 7, New York 6, Milwaukee 3, Brooklyn and Boston 2 each, Washington, Nashville, Worcester, Cambridge, Springfield and Brockton 1 each. From whooping-cough Brooklyn 6, New York 5, Philadelphia, Cleveland and Nashville 3 each, Boston, Washington and Charleston 1 each. From cerebro-spinal meningitis Washington 5, New York, Cleveland and Lynn 2 each, Worcester, Somerville, Gloucester and Pittsfield 1 each. From small-pox Brooklyn 7, New York 5, Boston 2. From malarial fever Brooklyn 5, New York 4, Philadelphia 2, Springfield 1.

In the thirty-three greater towns of England and Wales with an estimated population of 10,458,442, for the week ending March 31st, the death-rate was 20.0. Deaths reported 4,010: acute diseases of the respiratory organs (London) 347, measles 210, whooping-cough 158, diphtheria 96, scarlet fever 51, fever 46, diarrhoea 40, small-pox (West Ham 5, Birmingham 3, Bristol, Manchester and Oldham 1 each) 11.

The death-rates ranged from 12.2 in Portsmouth to 25.8 in Salford; Birmingham 20.0, Bradford 17.2, Bristol 14.5, Croydon 19.6, Halifax 21.3, Hull 18.4, Leeds 15.0, Leicester 19.8, Liverpool 24.5, London 20.8, Manchester 22.7, Newcastle-on-Tyne 21.2, Norwich 19.2, Nottingham 20.8, Plymouth 23.7, Sheffield 18.6, Sunderland 19.2, Swansea 16.9, West Ham 15.8.

METEOROLOGICAL RECORD.

For the week ending April 7th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 7, 1894, TO APRIL 13, 1894.

Leave of absence for one month is hereby granted CAPTAIN OGDEN RAFFERTY, assistant surgeon, with permission to apply for an extension until the 20th of May next.

The following named officers of the Medical Department will report in person for temporary duty until further orders, as follows: FIRST-LIEUT. CHARLES WILLCOX, assistant surgeon, to the commanding officer, Angel Island, California. FIRST-LIEUT. CHARLES E. B. FLAGG, assistant surgeon, to the commanding officer, Alcatraz Island, California.

THE INTERNATIONAL ASSOCIATION FOR THE ADVANCEMENT OF HYGIENE.

The Ninth Exposition of Hygienic and Alimentary Products, under the auspices of this Society will be held at Rome, in June next, in the Palais des Beaux-Arts, under the Presidency of Dr. Baccelli, Minister of Public Instruction.

Authors and editors of publications relative to hygiene are requested to send copies of their works to M. Louis De Vriese, Administrator-General, Rue des Régnées 3, à Gaud, Belgium.

HARVARD MEDICAL SCHOOL.

EVENING LECTURES.

The next lecture will be given on Wednesday evening, April 25th, by Assistant Professor T. M. Rotch, at 8 o'clock. Subject, "Infant Feeding." Physicians are cordially invited.

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—A regular meeting of the Society will be held at the Medical Library, No. 19 Boylston Place, on Monday, April 23, 1894, at 8 o'clock, P. M.

Dr. A. Thorndike: "Acute Arthritis in Infants, in the Hip-Joint." Discussion opened by Drs. E. H. Bradford and H. L. Burrell.

Dr. G. H. Washburn: "An Interesting Obstetrical Case." Discussion by Drs. J. G. Blake, C. E. Stedman, E. Reynolds. JOHN T. BOWEN, M.D., Secretary.

THE BOSTON MEDICO-PSYCHOLOGICAL SOCIETY will hold its next meeting on Thursday evening, April 19, at eight o'clock, at

the University Club, 270 Beacon Street, Drs. Walter Channing, R. T. Edes, E. V. Scribner and C. E. Woodbury, entertaining.

The Society invites the Faculty of the Harvard Medical School and the Staffs of the Massachusetts General Hospital and City Hospital to be present.

Dr. H. M. Hurd, of Baltimore, will read a paper entitled, "Some of the Mental Disorders of Childhood and Youth."

Members are requested to inform the Secretary whether or not they can be present.

H. C. BALDWIN, M.D., Secretary.

PENNSYLVANIA STATE MEDICAL SOCIETY.—The annual meeting of the Pennsylvania State Medical Society will be held in Philadelphia, May 15, 16, 17 and 18, 1894. The annual addresses before the various sections will be given by the following gentlemen: "Medicine," W. S. Foster, M.D., Pittsburg; "Surgery," G. D. Nutt, M.D., Williamsport; "Obstetrics," E. E. Montgomery, M.D., Philadelphia; "Mental Disorders," T. M. T. McKennan, M.D., Pittsburg; "Hygiene," J. H. Wilson, M.D., Beaver; "Ophthalmology," Geo. E. de Schweinitz, M.D., Philadelphia.

RECENT DEATHS.

DANIEL E. MARSTON, M.D., died in Monmouth, Me., April 14th, aged fifty-eight years. He graduated from Bowdoin in 1859 and served in the army during the rebellion.

CORYDON C. FOID, M.D., for forty years Professor of Anatomy and Physiology in the University of Michigan, died at Ann Arbor, April 14th, aged eighty-one years.

JOSEPH H. WORKMAN, M.D., died April 15th, aged eighty-nine years. He was the first President of the Ontario Medical Council and was for twenty-five years Superintendent of the Toronto Asylum for the Insane.

SEBASTIEN DIDIER LHERITIER, M.D., died in Paris recently, aged eighty-five years. He was private physician to Napoleon III and a prominent member at the court during the Second Empire. He was inspector of the mineral springs at Plombières.

BOOKS AND PAMPHLETS RECEIVED.

Pernicious Malarial Fever. By George Dock, M.D., of Ann Arbor, Michigan. Reprint. 1894.

Charaka-Samhita. Translated into English and published by the Avinash Chandra Kaviratna. Part VII. Calcutta. 1894.

The Johns Hopkins Hospital Reports, Vol. IV, No. I. Report on Typhoid Fever. Baltimore: The Johns Hopkins Press. 1894.

Faradism as an Analgesic in the Loosening of Joint-Adhesions. By Douglas Graham, M.D., Boston, Mass. Reprint. 1893.

The Hospital at 24 McLean Street, A Statement of its History, its Managers, its Doings and the Result of its Work in 1893. The Sixty-first Year of the Boston Lying-in Hospital. Boston. 1894.

Lectures on Surgery. By David W. Cheever, A.B., M.D. (Harv.), Professor of Surgery, Emeritus, in the Medical School of Harvard University; Senior Surgeon of the Boston City Hospital, etc. Boston: Dammell & Upham. 1894.

Clinical Manual of the Study of Diseases of the Throat. By James Walker Downie, M.B., Fellow and Examiner in Aural Surgery for the Fellowship of the Faculty of Physicians and Surgeons, Glasgow. New York: Macmillan & Co. 1894.

Transactions of the American Dermatological Association at its Seventeenth Annual Meeting held at Milwaukee, Wis., on the 5th and 6th of September, 1893. Official Report of the Proceedings by George Thomas Jackson, M.D., Secretary. New York. 1894.

Gonorrhoea; Being the Translation of Blenorhoea of the Sexual Organ and its Complications. By Dr. Ernest Finger, Docent at the University of Vienna. Third revised and enlarged edition, with seven full-page plates in colors and thirty-six wood engravings in the text. New York: William Wood & Co. 1894.

A Manual of Practical Obstetrics. By Edward P. Davis, A.M., M.D., Professor of Obstetrics and Diseases of Children in the Philadelphia Polyclinic; Clinical Lecturer on Obstetrics in the Jefferson Medical College; Clinical Professor of Diseases of Children in Woman's Medical College, etc. Second edition, revised and enlarged, with 134 illustrations and 16 full-page plates, several of which are colored. Philadelphia: P. Blakiston, Son & Co. 1894.

Methods of Pathological Histology. By C. von Kahliden, Assistant Professor of Pathology in the University of Freiburg. Translated and edited by H. Morley Fletcher, M.A., M.D., Cantab., M.R.C.P., Casualty Physician to St. Bartholomew's Hospital and Assistant Demonstrator of Physiology in the Medical School. With an introduction by G. Sims Woodhead, M.D., Director of the Laboratories of the Conjoint Board of the Royal Colleges of Physicians (Lond.) and Surgeons (Eng.). London and New York: Macmillan & Co. 1894.

Original Articles.

OBSERVATIONS ON CASES OF FIBROID TUMOR OF THE WOMB.¹

BY FRANCIS MINOT, M.D.

In offering some remarks on the cases of uterine fibroid which have come under my notice, I do not pretend to advance any new views as to the etiology, the symptoms or the treatment of the disease. I shall chiefly allude to certain points in connection with its diagnosis, and to some of the symptoms which appear to me to be of interest, and to indicate their practical value.

It is remarkable that a structural disease of the womb, causing a considerable enlargement of the organ, sometimes giving rise to an annoying disfigurement, especially if the patient be unmarried, and generally accompanied by a more or less profuse hæmorrhage which often lasts for years, should in many cases not only be free from danger to life, but that it should often interfere but little with the occupations and the comfort of the patient.

I regret that out of a large number of patients with fibroid tumor, who have come under my observation during a practice of forty years, I have preserved sufficiently detailed notes to be of value in only thirty-four cases. Of these, the number of patients who were, or who had been married, is twenty-one, their average age being thirty-six years. The oldest patient was fifty-two years; the youngest, twenty years old.

The age at which the first symptoms of the disease appeared in twenty-six cases of which trustworthy statements could be obtained, varied from twenty years to fifty-two years. Arranged according to decades, the first symptoms were noticed:

Between the ages of 20 and 30	in 10 cases
Between the ages of 30 and 40	in 13 cases
Between the ages of 40 and 50	in 2 cases
Between the ages of 50 and 60	in 1 case

In one case the first symptom appeared at the age of twenty years and two months; in another at twenty-two years; in another at fifty-two years. The average age was about thirty years. So far as this small number of statistics goes, it appears that the social state has but little influence in the etiology of uterine fibroid, and that the disease may appear at any period of life after twenty, perhaps most frequently between thirty and forty, and either in single or married women.

The diagnosis of uterine fibroid is in many cases comparatively easy. The combination of profuse menorrhagia, often passing into metrorrhagia, with a hard tumor connected with the uterus and felt through the abdominal wall, is usually enough to remove all doubts as to the disease. Both of these symptoms, however, may be absent.

(1) There may be absolutely no menorrhagia, or the flow may amount to no more than is often observed in patients who are free from uterine disease, as in the following case:

A lady, twenty-eight years old, single, was brought to me March 11, 1873, by her physician, in consequence of a feeling of distention in the abdomen and the discovery of a tumor in the left iliac region. There was no menorrhagia. A large, rounded tumor occupied the left pubic region, extending nearly to the

navel, and a little to the right of the median line. It was irregular, but not distinctly lobular, cervix uteri very low, just beneath the pubes. The posterior region of the pelvis was filled by the tumor, as was evident by rectal examination. The tumor was somewhat movable above. August 17, 1893 (more than twenty years afterwards), the patient's physician wrote to me: "There has been occasionally some increase of menstrual flow, but never amounting to excess; she is nearly reduced to her natural size, is in fair condition and enjoys life."

April 29, 1875, I saw in consultation with the late Dr. D. H. Storer, a patient with a "large uterine tumor, divided into several distinct lobules, distending the abdomen as much as a pregnant uterus at the fifth or sixth month; no hæmorrhage; no pain."

The first symptom noticed may even be a suppression of the menses. A young woman, twenty-one years old, was brought to me by the late Dr. Snow of Newburyport, August 14, 1888. She had had no catamenia since the previous November. In all other respects her health had been good. There had been progressive enlargement of the belly. The abdomen was distended by a smooth, hard tumor, occupying its lower half, which was found by bimanual examination, to be connected with the uterus. The navel was nearly obliterated, as in pregnancy at the eighth month. No foetal heart-beat and no placental murmur could be heard. The breasts were virginal in appearance, the hymen was intact, ballottement gave no evidence of pregnancy.

(2) As regards abdominal tumor, we must remember that this is usually absent in uterine polypus unless the latter be extremely large; and if there be no hæmorrhage, it might not be suspected. I saw, with the late Dr. A. B. Hall, June 21, 1868, a mulatto woman forty years old, who for a year previously had complained of uneasy sensations in the pelvis and a profuse vaginal mucous discharge. There was no hæmorrhage, and no abdominal tumor could be felt, but the vagina was completely filled with a firm mass, connected with the interior of the uterus by a pedicle one inch thick. The pedicle was severed close to the uterine wall with scissors, and the tumor removed with very little loss of blood. It was an ordinary fibroid, about the size of the fist. The patient did well.

An intro-mural tumor may be so small as not to be felt, either by external or internal examination, and yet give rise to much hæmorrhage. Several years ago a domestic in the family of Dr. Davidson of Gloucester, twenty-eight years old, married, had had for more than a year abundant and frequent uterine hæmorrhages. There was no tumor to be felt by Dr. Davidson, who accordingly dilated the cervix uteri with sponge tents, and detected a tumor in the uterine wall apparently about the size of a boy's marble. He sent her to the Massachusetts General Hospital, where the tumor was removed. It was an ordinary fibroid, "as large as a very large horse-chestnut." The patient did well.

The diagnosis of uterine fibroid may be obscured by the prominence of symptoms which are not characteristic of that disease. May 24, 1889, I was called to see a nursery-maid, thirty-six years old, who had always enjoyed good health. Menstruation rather free, but otherwise normal. She had never had any bladder trouble before, but on that day, on rising, she was unable to make water. After breakfast she had a movement of the bowels, as usual, but still could make

¹ Read before the Obstetrical Society of Boston, February 10, 1894.

no water. Although feeling uncomfortable, she took one of the children to school. In the course of a few hours, the discomfort amounted to distress, in which condition I found her at three o'clock P. M., and drew off with a catheter about two quarts of urine without any difficulty, and a tumor was felt, *per vaginam*, nearly filling the pelvis. Externally, the tumor was felt occupying nearly the whole of the supra-pubic region, and extending halfway up to the navel, with a projection towards each flank. April 11, 1890, nearly a year afterward, I was called to see her again for the same difficulty, and drew off about three pints of urine. During the interval between my two visits she had had no difficulty in micturition. She had had no unusual fatigue, and no exposure to cold. Since my previous visit, the tumor had extended upwards as far as the navel, and also downward in the pelvis; the os uteri was low down and closed, and the cervix was obliterated. The catamenia were regular, profuse, lasting eight or nine days. Quite recently I have been informed that the patient has had no farther recurrence of the bladder difficulty, and is in good health.

Urgent urinary symptoms have been comparatively rare in cases of uterine fibroid under my observation, but in several instances there was more or less irritability of the bladder; several patients complained of painful and frequent micturition. One case was complicated with pelvic inflammation and cystitis. One patient had frequent micturition day and night. In another case, the first symptom noticed was frequent micturition; the patient made water every few hours during the day, and several times during the night. There was no pain in the act, but much pain if she was compelled to hold her urine long.

Interference with the functions of the rectum was reported by none of the patients of whose cases I have preserved notes.

The diagnosis between fibroid tumor of the womb and pregnancy is generally easy, though not always so, and it is hardly necessary to say that the most careful examination should be made in such cases before giving an opinion which might compromise the reputation of a patient. I have already mentioned the case of an unmarried woman whose external appearance, caused by a large uterine fibroid, was strongly suggestive of pregnancy. Another case was that of an unmarried lady, a teacher of a young ladies' school, who consulted me on account of the disfigurement caused by a large fibroid of the womb.

Cases of fibroid complicated with pregnancy are not very rare, and it is remarkable that the latter is often not interfered with, that the labor may be attended with no serious difficulty, and the child be born alive. In April, 1876, I saw with Dr. Winslow of Groton, a lady who, four weeks previously, had been confined at full time, the child being alive and well at the time of my visit. There had been some delay in the passage of the head, which was found to be caused by a fibroid growth of the size of the fist, attached by a pedicle to the posterior wall of the uterus. A few days after the labor, the patient was attacked by phlebitis of both arms and one of the legs, and she died a week after I saw her, but there seemed to be no connection between the presence of the tumor and the phlebitis.

In March, 1887, I saw a lady who had been married somewhat over a year. A short time before her marriage (the menstruation having always been remarkably regular, without pain, and normal in amount),

she had noticed a tumor in the abdomen, which had remained of the same apparent size ever since. The last appearance of the menses was about three months before my visit, and the patient exhibited the usual subjective and objective symptoms of pregnancy. The tumor was smooth, rounded, hard, not tender, and was situated above the right pubic ramus, towards the iliac fossa. The upper margin was about three inches below the navel. It was somewhat movable, and was connected with the womb, as was shown by bi-manual exploration. The patient was a stranger visiting Boston, and I have not heard of her since.

Fibroid tumor of the womb may, of course, give rise to abortion. A woman twenty-six years old, who had been married eight months, consulted me January 10, 1879. She had never had menorrhagia, though frequently dysmenorrhœa, before marriage. Twice since marriage, she had suspension of the catamenia for one or two periods, followed by hæmorrhage and the expulsion of a mass. In the left iliac region was a round, hard movable body of the size of a horse-chestnut, and a large tumor occupied the left side of the pelvis, reaching as high as the brim, connected with the uterus and with the smaller one. There was no external enlargement from the tumor.

Of the symptoms connected with fibroid disease of the womb, perhaps the most serious, certainly the most rebellious to treatment and the most annoying to the patient, is metrorrhagia. Patients are sometimes encouraged to believe that after the period of the menopause, there will be a permanent suppression of the hæmorrhage. This, no doubt, often occurs, but in my experience there have been several exceptions to the rule, and I have at present four such under my observation. A remarkable feature of the symptom, in many cases, is its capricious behavior. It may long resist treatment, and then, after treatment has been abandoned, it may cease spontaneously for years, only to return again, to the despair of the patient and of the doctor. In two cases which have been under my observation for many years, there have been intervals of complete suspension of hæmorrhage lasting in one patient, for eight years, and in the other for two years, apparently not due to treatment; but in each there was a subsequent return of the bleeding. In some cases, the hæmorrhage is replaced by a profuse serous discharge, which is hardly less annoying to the patient.

As a rule, the treatment for hæmorrhage from uterine fibroids is unsatisfactory. It is rarely that a patient is cured, though in many cases, an arrest of the bleeding for a longer or shorter time may be obtained. Among the various remedies which have been recommended, ergot has the highest reputation. It will often check the hæmorrhage temporarily, but I have not met with an instance of cure following its use, unless in patients who have nearly reached the period of the menopause, when there is in many cases a spontaneous cessation of the flow. Chian turpentine has also in my hands proved a valuable remedy, perhaps superior to ergot, but I have not had enough experience in its employment to be sure of this. To be of any use, these remedies must be given in full doses and several times a day.

We should suppose that restriction from active exercise would be essential in the treatment of the hæmorrhage, but two of my patients assured me that exercise had no effect in increasing it. One of them had spent several weeks in the Adirondacks, during which

time she not only took long walks, but did a good deal of mountain climbing, without any unfavorable effect. She is forty-eight years old, and has had a large tumor for many years, with, at times, profuse hæmorrhage, which has not yet wholly ceased.

As to the treatment of the anæmia and debility, which are the results of the long continued loss of blood, I have nothing to say which would justify me for trespassing any longer upon your attention.

The surgical treatment of uterine fibroid has until lately been rarely attempted, on account of the large mortality which attended it; but the great improvements in abdominal surgery which have accompanied the adoption of antiseptic methods, justify the hope that many cases of this disease in which life, even if not in actual danger, is an almost intolerable burden, may be permanently relieved by such means.

THE NON-SURGICAL TREATMENT OF CHRONIC PELVIC INFLAMMATIONS AND THEIR SEQUELÆ.¹

BY F. H. DAVENPORT, M.D.

SOME of the most perplexing problems in gynecology are the common ones which meet us in the course of our every-day practice. There are, of course, the grave cases where the physician is called upon to decide the question of an operation involving life and death, but these, fortunately, are rare. On the other hand, the majority of the cases we are called upon to treat are of such a nature that the appropriate methods of treatment suggest themselves, and the consensus of medical opinion, justified and backed up by experience, approves the choice. The retroversion is rectified, and the displaced organ held comfortably in its normal position by a pessary. The lacerated cervix, causing a long train of local and general symptoms, is sutured, and the troublesome symptoms gradually disappear. The rupture of the perineum which has destroyed the integrity of the pelvic floor is repaired, with gratifying result. A uterine polypus is snipped off, and a troublesome, perhaps dangerous, hæmorrhage is instantly checked.

These are familiar examples of that class of cases where the trouble instantly suggests the appropriate measures for its relief. They are the most satisfactory to the physician and the patient as well.

Between these two sets of cases occur in moderate frequency those where there is no well-recognized line of treatment, and where the consultant is obliged to choose, out of a large variety of therapeutic measures, that which seems best adapted to the case, with the hope that it may afford some measure of relief.

These rather trite general considerations have been suggested to my mind by my experience in the last few years in the treatment of the secondary results of chronic pelvic inflammations. Not that I feel that I can claim any new or royal road to success in such unpromising cases, but with enlarged opportunity and experience one unconsciously weeds out what seems superfluous, and in following large numbers of cases for a length of time, can estimate final results with a more unprejudiced mind. It is also with a hope of learning from other men what they have found of value in such cases that I have ventured to discuss this rather threadbare subject.

And, first, I would like to define as clearly as I may what I mean by chronic pelvic inflammations and their sequelæ.

Pathologically, we can in general say that the starting-point is some more or less extensive localized pelvic peritonitis. As a consequence of this, we have adhesions between the layers of the peritoneum investing the pelvic viscera, resulting in displacements and thickenings. These processes may be so extensive that the whole pelvis is affected, or they may be confined to one side, or to a single limited area of one side. Thus the uterus, ovaries, tubes and anterior wall of the rectum may be so matted together that they form one mass, in which the various organs are indistinguishable by bimanual examination, or there may be present but a single thickened point to mark the presence of a former inflammation. These are the cases which ten and fifteen years ago were all classed under the head of pelvic cellulitis. We now recognize that they are the effects of a localized pelvic peritonitis, the cause of which may be obscure, but which in the majority of cases is the result of the extension of some inflammatory process from the uterus through the tubes to the peritoneum. Gonorrhœal abortions, septic processes, the result of meddlesome or uncleanly treatment, or trauma, are the most common sources of such affections. While adhesions are the most evident results of the peritonitis, yet the uterine, tubal and ovarian conditions which precede or accompany the peritonitis go to make up the complete pathological picture, and may be considered as part of the disease to be treated. It is the general condition of the whole pelvic organs, the congested uterus, the catarrhally-affected tube, the adherent, prolapsed ovary, and the thickened, glued-together layers of the peritoneum, which I consider under the title of chronic pelvic inflammations and their sequelæ.

As a rule, these women come to us only when their symptoms have existed so long and have become so burdensome that relief is imperative. I need not go into a detailed account of the symptoms complained of. They are those common to the majority of pelvic lesions, and there is nothing pathognomic among them. Even a history of any acute attack is often wanting. In a general way they are: pain of all varieties and degrees of intensity, menstrual disturbances, leucorrhœa and reflex functional disorders. To attempt to describe them in detail would be to give a list of almost all the possible ills that "flesh is heir to."

On examination, what do we find? Very often there is so much sensitiveness that our examination is very unsatisfactory. We may find, and perhaps this is as common a condition as any, a congested, sensitive uterus in a position of retroversion or flexion, partially fixed or quite immovable, and very probably the seat of a catarrhal endocervicitis. In the neighborhood, either at the sides or behind, are sensitive swellings. What these are it is usually impossible to say at our first examination, for the extreme sensitiveness precludes all possibility of making any differential diagnosis.

Such is the clinical aspects of these cases, and such the anatomical condition as far as our examination can reveal it. I purposely in this paper exclude pyosalpinx, believing that for that condition palliative measures rarely are sufficient, and that the line of treatment to be outlined later has in it an element of danger.

¹ Read before the Obstetrical Society of Boston, February 10, 1894.

Suppose such a patient presents herself for treatment, and on examination we find the complex conditions which I have described. All that we can say certainly is that the uterus is displaced backwards and bound down, and that in the immediate neighborhood there are sensitive swellings. In the absence of direct evidence that we have pus tubes or ovarian or parovarian tumors to deal with, I claim that our prognosis, though guarded, should not be discouraging, and that our treatment should be conservative.

As the main obstacle to a more accurate diagnosis is the sensitiveness, our first efforts should be towards overcoming this. No agent has proved half so efficacious in my hands towards this end than glycerine. The hot-water douche cannot begin to compare with it in efficacy, first, because the principle on which it acts is not the correct one, and second, because its effect is not so lasting. The douche, by contracting the blood-vessels, drives the blood out of the parts, to be sure, but probably acts only on the surface and a short distance below it, and fails to reach the deeper tissues. Glycerine, from its affinity for water, draws from the blood-vessels the serum, and thus, by directly unloading those in the immediate vicinity, promotes a more regular and natural circulation in the part. To accomplish this end, however, a large amount of glycerine must be used, and in such a way as to be easily borne. For this purpose I use a prepared wool, which has the great advantage over cotton that it is very elastic, does not mat, and will hold a large amount of glycerine in its meshes. This I roll up into such a sized tampon as will suit the case, tie a string about it, and thoroughly soak it in glycerine. Such a tampon will need half an ounce to do thoroughly good work. I place this in the vault of the vagina, and direct the patient to wear it for forty-eight hours if it is comfortably borne. If it becomes uncomfortable, she may remove it and take a douche.

A tampon of this size will usually cause enough watery discharge to necessitate the use of from four to six napkins in the first two days. The discharge then usually stops, and the tampon ceases to be of use except as a moderate support. The fact that it is of some value as a support is a second respect in which it is of more advantage than the hot-water douche.

The third day I repeat it, and each third or fourth day until the sensitiveness is diminished enough to admit of the second step in the treatment.

Painting the vault of the vagina with Churchill's iodine is of considerable value as a secondary means of relieving pain and congestion. I have, however, found ichthyol much more effective as an analgesic, and it can be very conveniently combined with the glycerine treatment. A small wool tampon soaked with a mixture of ichthyol and glycerine, one part to eight, is first placed against the cervix, and the larger tampon inserted after it. I cannot say that I have observed the melting away of inflammatory products under the use of ichthyol which have been reported by some writers, but its effect on pain has been very marked.

The second indication for treatment is to restore the mobility of the uterus, and to stretch or break up the adhesions. This can only be attempted after the sensitiveness has been materially lessened. The method may be conveniently described as consisting of two steps: first, putting the adhesions on the stretch, and second, keeping them so. In the first place, I would

warn against the use of the sound or any repositior to replace the uterus. Such an instrument used for such a purpose is uncertain and dangerous. There is no better or safer repositior than the finger. In order to bring the adhesions on the stretch, the anterior lip of the uterus is seized with the double tenaculum and moderate traction made on it, while one or two fingers of the left hand, inserted into the posterior cul-de-sac, gently lift the uterus and carry it forward. In this way the adhesions can usually be felt or the inflammatory swellings palpated. A very effective massage may now be practised, of short duration, but with gradually increasing force, gently putting the tight bands on the stretch, or rubbing the hard masses with the tips of the fingers. I lay great stress in the treatment of these conditions on this lifting and massage of the uterus, and the inflammatory products in its immediate neighborhood. I am confident that I can get good results in much less time than I could formerly by packing alone.

When the uterus has been raised as much as is safe, the vagina is then thoroughly packed, just as firmly as the patient can bear, and the tampon left three, or at the most, four days. I usually pack a second time before repeating the lifting and massage, as it is apt to cause sensitiveness if it is repeated at too short intervals.

There will come a time in the treatment of some of these cases when further attempts at restoring the uterus to its normal position seem useless. The adhesions are too firm to be separated, and though there is some improvement, yet the pelvic conditions are not yet normal. Sometimes the uterus is still retroverted and the inflammatory thickenings still prominent. To suspend treatment here is to lose all we have gained, and the most satisfactory way to prevent a return to the former condition is the use of a pessary.

Two or three years ago my attention was called to an article in the *American Journal of Obstetrics* for 1891, by Dr. Sarah E. Post, on the use of the inflated ring-pessaries, and as their principle seemed to me to be a good one for the class of cases which I am now describing, I determined to adopt it. I came to the conclusion, however, after a short trial, that the solid elastic rings of large calibre, did better than the inflated pessaries, as giving more efficient support, and not causing trouble by gradually collapsing. These rings come of several sizes. There are two varieties, the solid rubber ones, and those composed of a spiral spring covered with rubber. The former are very much to be preferred, as after having been used a while the latter become wrinkled, and are apt to cause irritation.

I have found this pessary of great value in these cases. In the first place, it supports and elevates the uterus. This it does without causing as much pressure on any particular part of the vaginal vault as do the pessaries constructed on the Hodge model, which are very apt to press on just the most sensitive points; nor does it push the uterus up quite so high as the others, which in an adherent uterus is an advantage. It also relieves pain by immobilizing the organ to a certain extent, and yet allowing more freedom of motion than a Hodge. It encircles the cervix with a firm, elastic pressure, and while yielding perfectly to the natural movements of the uterus, it prevents any sudden jar from dislocating the organ too much. A second factor in relieving the pain has to do with the circulation of

the uterus. The even pressure around the cervix and upwards must to a certain extent equalize and regulate the blood-supply, and so favor the relief of the congestion. This will in turn diminish the sensitiveness of the nerves.

Not the least beneficial effect of this pessary is seen in the changes which gradually take place in the pelvic tissues themselves. Wearing it has resulted in, to a degree, restoring the mobility of the uterus, improving its position by thinning and stretching bands of adhesions, rendering sensitive swellings smaller and less sensitive, and reducing the size of the womb itself. This result had followed too often to be a chance coincidence, and I now confidently expect these results to a greater or less degree in all suitable cases. Examination from month to month will show a gradual improvement in the condition of the pelvic organs, which goes hand-in-hand with such an amelioration of the patients' general health that they call themselves practically well.

This *résumé* of my method of procedure in this class of cases, the wool-glycerine tampon, ichthyol, massage and packing, and finally, the cushion-pessary, does not, I confess, compare in brilliancy with the well-known surgical procedures which are advocated for this type of gynecological cases, but I claim, first, that where doubt exists as to the true condition of the pelvic organs, this method clears up the diagnosis, and in a majority of cases, and I speak advisedly, renders an operation unnecessary; and second, that the results obtained are sufficiently gratifying to render the prognosis less grave than is often supposed.

By way of illustration, I propose to give briefly the histories of a few cases in which this line of treatment has been carried out either in part or wholly.

CASE I. Mrs. B., thirty-five years old, was brought to me in December, 1891, by her physician, who had treated her for an obstinate retroflexion for a long time. She had had one child six years ago. Her principal complaints were great pain and soreness in the lower abdomen and back, especially the coccyx, dysmenorrhœa, irritable stomach, severe headaches and inability to take much exercise. Her physician had tried to relieve her symptoms, and to replace the uterus by applications and tampons, but without success. I found a heavy, retroflexed uterus only moderately movable, a slightly-lacerated cervix and a sunken perineum. Behind the uterus were several round bodies, about the size of a filbert, which were exquisitely sensitive to the touch, and which I took to be swollen glands. Any attempt to raise the uterus bi-manually was accompanied by so much pain from pressure on these bodies that it had to be abandoned. So, too, the wearing of a retroversion or flexion pessary was impossible.

After a little preliminary packing I adjusted a cushion-pessary, which gave her more relief than anything else. She has now worn that for about six months, and lately has been able to take care of it herself. The last time I saw her there was a most marked improvement in the condition of the pelvic organs. The uterus was much more movable, and could be raised nearly to its normal position, the sensitive bodies behind in Douglas's cul-de-sac had nearly disappeared, and she is now ready to have the cervix and perineum repaired.

CASE II. Mrs. B., twenty-seven years old, consulted me in July, 1891, for menorrhagia and dysmen-

orrhœa. Six years previous to my seeing her she had jumped from the box of a stage-coach to the ground, which was followed by an attack of pelvic peritonitis which confined her to bed for six weeks. After her recovery from the acute attack she suffered from severe pain at her monthly periods and profuse hæmorrhages. Her general health, especially as regards her nervous strength, had begun to suffer. She had never had any local treatment. Examination showed a firmly adherent, retroverted uterus, cul-de-sac partly obliterated by thickened tissue, and yielding very little to pressure by the finger. As she expected to be married in a month or two, no treatment was begun for about six months. Then tampons, packing and iodine were used for some time, and a Meigs ring was finally inserted. The improvement was most marked, both as regards her symptoms and the condition of the pelvic organs. The uterus, while still in the first degree of retroversion, was smaller and the adhesions less firm, allowing considerable mobility. Two years after marriage she miscarried at two months. A second pregnancy has resulted happily in the birth of a child last December.

CASE III. Miss C. first consulted me in 1888. Was twenty-one years old. Had a fall when eleven years old, since which time has suffered from a lame back, pain in back and right groin, headaches, delayed menstruation, usually five weeks, but occasionally going from three to six months, dysmenorrhœa lasting from half a day to a day, leucorrhœa and depression of spirits. She was wearing a pessary when she came to me, but I found the uterus retroflexed over the top of it, and apparently adherent. The right ovary was enlarged and sensitive and prolapsed. She had consulted one of the most eminent gynecologists in New York, who had advised removal of the tubes and ovaries. After packing firmly for a month, although the uterus was not thoroughly forward, a bulb pessary was introduced, to be worn during the catamenia. This proved so comfortable that she wore it all summer. In September the uterus was in a position of right lateral flexion, a position that I have often observed an adherent uterus assume as it changes from a backward position to the normal. Sometimes, as in this case, it remains drawn to one side. In March, 1889, she married, became pregnant in June, and is now the mother of three children.

CASE IV. Miss M., thirty-three years old, had been well until two years ago, when, after running a heavy machine, she began to suffer with a feeling of pressure and darting pains in the rectum, and a feeling of heat in the lower part of the back. She also suffered from leucorrhœa. She was unable to work on account of the pain in her back. I first saw her October 18, 1892, and found the uterus retroverted and tightly bound down by adhesions, some of which, especially on the right side, could be felt as strong bands. Three weeks' treatment by firm packing and raising the uterus manually brought the uterus into fair position, though one strong band of adhesion on the right failed to give way. A cushion-pessary was introduced, and by January she was able to resume work. She still is wearing the support, and there is steady improvement in the mobility of the fundus, and the adhesions grow more defined and thinner.

These cases may, perhaps, be considered typical of the class in which I have found the treatment I have outlined of benefit. As I said at the outset, there is

no new principle involved, but possibly the particular application of these various remedial agents may be suggestive. It will, at any rate, emphasize what may be called the conservative way of looking at the treatment of pelvic inflammations and their results.

THREE CASES OF OCCLUSION OF THE SUPERIOR MESENTERIC ARTERY.¹

BY W. T. COUNTELMAN, M.D.,

*Shattuck Professor of Pathological Anatomy, Harvard University;
Pathologist to the Boston City Hospital.*

THE cases which I present to-night are not only interesting in themselves, but show the tendency of rare pathological conditions to occur in groups. All of the autopsies were made within the last two weeks, and they are the first specimens of the sort which I have seen for a number of years.

CASE I. The first specimen which I shall show comes from an autopsy made for Dr. J. L. Hildreth. The clinical history of the case is as follows:

Mrs. X., aged eighty-five. Although feeble for a number of years, the general health was fairly good with the exception of attacks of bronchitis at intervals. Twelve days before death she had not been feeling well, and went to bed somewhat earlier than the usual hour. She was not able to sleep, and called an attendant at ten complaining of pain in the bowels. The pain became more intense, and Dr. Hildreth first saw her at 2 A. M. At that time she was restless, complained of intense pain in the bowels; pulse 70. No physical signs could be made out either in chest or abdomen. The pain was referred vaguely to the right iliac fossa. An opiate was administered, and repeated until pain was allayed. In the morning the pain returned in the same place. A large enema was given, which produced no results. There was no passage of flatus from the bowels. The abdomen became more distended, and the pain seemed localized in the right iliac fossa. At the end of the third day the condition continued the same. No vomiting. The temperature 1° sub-normal. Dr. Marcy, of Cambridge, saw patient in consultation on the fourth day. Diagnosis made of complete obstruction of bowels. An operation was suggested, but not urged. All of the symptoms continued until the seventh day when the temperature was 2½° sub-normal. From this point the temperature gradually arose, and before death reached 2° above normal. Vomiting commenced on the fourth day before death, finally becoming fecal. The pulse became quicker and weaker, and death took place twelve days after the first attack.

At the autopsy the abdomen was greatly distended. The intestines were enormously distended and somewhat congested. In the lower lobes of both lungs and in the posterior portions of the upper lobes there were numerous areas of consolidation. The pleura over these portions of lung was covered with a fine fibrinous exudation. The consolidation in the upper lobes had a distinctly lobular distribution. In the lower lobe of the left lung the consolidation was more extensive, but here, also, was apparently produced by the confluence of smaller foci. There was extreme fatty degeneration and atrophy of the heart and extensive atheromatous degeneration of the aorta. The heart was perfectly flaccid and so soft that the finger could be thrust

through the ventricle at any point. The entire abdominal aorta was covered with flakes of calcification. On these rough, calcified plates there were numerous thrombi. The most extensive thrombus was on the anterior surface of the aorta just above the origin of the superior mesenteric, and almost completely occluded the opening of the artery. The thrombus extended for a very short distance into the artery, but the artery itself was free from both emboli and thrombi. The small intestine was greatly distended, and in places there were a few small ecchymoses; but there was neither intense congestion nor at any point complete infarction.

In this case it seems probable that the partial occlusion of the artery by the thrombus in the aorta was, in the weakened condition of her circulation, sufficient to cause entire paralysis of the bowel and obstruction from this reason.

Cultures made from the tissues gave pneumococci in the consolidated portions of the lung; in the spleen and in the liver. In all of the organs colon bacilli were found.

CASE II. The clinical history of this case, of which the heart, aorta and mesentery were shown, is this:

R. T., aged sixty-one. Entered hospital January 19th. Complained of pain in left foot and ankle. The parts were much swollen, cold and blue. Three days afterwards the right foot showed the same process. Two days before death complained of pain in abdomen, pulse gradually sank and death took place.

At the autopsy the intestines were found enormously distended. The peritoneum was covered with a fibrino-purulent exudation, which in places produced a slight adhesion of the loops of the intestine. Pockets of pus were here and there found between the adherent loops of intestine. The entire small intestine was deeply injected and in the jejunum for a distance of about sixty centimetres the wall was greatly thickened and hæmorrhagic. In endeavoring to discover the cause of the peritonitis all the ordinary sources could be excluded. There was no evidence at any point of intestinal perforation. The mesenteric artery, however, was seen to be completely occluded by a thrombus about half-way between its origin and the intestine. This thrombus was firmly adherent to the wall and was totally occlusive. Beyond the thrombus there was a short space in the artery which was filled with a soft, dark coagulum, and further up, just opposite the area of intestine which shows the hæmorrhagic infarction and at a point in the artery where three branches are given off together, there was another thrombus which was also firmly adherent. On opening the intestine it was seen that on the mucous surface, in addition to the infarction, there were areas of distinct necrosis — some of these areas passing through the intestine. The source of the thrombus masses in the artery was evident from an examination of the aorta just above the heart. Here a roughened, calcified plate on the intima of the artery was seen, and adherent to this was a large thrombus. The thrombus in the aorta was evidently of a rather old date. In the kidney and in the spleen there were numerous infarctions produced by emboli. Some of these infarctions were anæmic, others hæmorrhagic. In some of them there was organization of the anæmic territory with cicatrization.

In both lower extremities, more marked on the right side, there was gangrene extending nearly up the knee. No line of demarcation as yet produced. The parts

¹ Specimens of these cases were shown at a meeting of the Boston Society for Medical Improvement.

were swollen, red, infiltrated with bloody fluid, large vesicles beneath the epidermis, and in places on the calf of leg the epidermis had desquamated. The arteries of both extremities occluded by thrombi. On the right side the thrombus extended up to the middle of the femoral artery; on the left side up to the popliteal. The occluded arteries were smooth, the thrombi tightly adherent.

On microscopic examination of the peritoneal exudation, colon bacilli were found in large numbers, and cultures from the peritoneum and from the other organs showed a general infection with colon bacilli. No other organisms were present in the cultures.

This case is of interest from the extent of the embolism, and also as showing peritonitis certainly produced by the colon bacilli, with a general infection of the other organs. From the examination of the intestine and the superior mesenteric artery, it would seem probable that there were here two emboli of different dates. The embolus towards the end of the artery, corresponding to the area of beginning hæmorrhagic infarction and necrosis, is evidently of older date than the one occluding the artery nearer its origin.

CASE III was from an autopsy in the Massachusetts Hospital for which I am indebted to Dr. W. F. Whitney. The clinical history is as follows:

A. B., seaman, aged sixty-two. At age of twenty, in bed for six months with general muscular tenderness and inability to use arms and legs. During this time there was some dyspnoea and slight palpitation. Since then he has had many similar painful attacks, but no cardiac symptoms until six months ago, when there was a sense of constriction in the region of the heart and marked shortness of breath. This condition increased constantly, and finally compelled him to cease work. Orthopnoea and anasarca then appeared, and have existed for the last month. When he entered the hospital the skin was somewhat jaundiced, and the respiration had at times the general Cheyne-Stokes characteristics. Four days later the abdomen became quite tender. On the following day the tenderness increased, and frequent loose stools occurred. There was hæmoptysis with physical signs of consolidation, and the pulse became very rapid and irregular. Four days later death took place. The abdominal pain and diarrhoea, with some elevation of temperature, persisting until the end.

I showed the mesenteric artery, with a portion of the intestine, from this case. Almost the entire small intestine was in a condition of hæmorrhagic infarction. The bowel contained a thin hæmorrhagic fluid; the walls of the intestine were greatly thickened from hæmorrhage. On the peritoneal surface of the intestine everywhere there was a very slight fibrinous exudation. The mesenteric artery from its beginning was entirely occluded by a thrombus. The source of the thrombus was not definitely made out. The heart was greatly enlarged. The aorta dilated, roughened, and the aortic valves relatively insufficient. It is probable that the thrombus in the mesenteric artery was of embolic origin, and came from a thrombus which had formed in the roughened aorta.

These cases are all of interest. In the first the clinical picture was that of obstruction without peritonitis. In the second there was a marked peritonitis and in the third only a slight beginning peritonitis. The cause of the peritonitis in the second case was evidently due to the colon bacillus. It is not necessary

to have an ulceration of the intestine or perforation in order for this organism to enter into the peritoneal cavity or into the tissues. There is no organism so commonly found in cultures from the various organs as is the colon bacillus. It is found in disturbances of the circulation of the intestine, such as is given in extreme chronic passive congestion. The resistance of the tissue in these cases is apparently so lowered that the organism finds entrance into the tissues. In all cases in which there are lesions of the mucous membrane of the intestine, it matters not how slight in character, the tissues will be invaded by this organism. In the second case in which there was marked peritonitis, the bacillus apparently found suitable conditions for growth in the necrotic tissue of the intestine, and it evidently passed through, or grew through, the intestinal wall into the peritoneal cavity. In a case which I autopsied at the City Hospital lately, there was a general fibrino-purulent peritonitis of slight degree in which the colon bacillus was found to be the only organism both in the peritoneal cavity and in the cultures. The source of the peritonitis in this case was in a small area of the intestine which had been incarcerated in a hernia. In the incarcerated portion of the intestine there was intense congestion with slight necrosis of the mucous membrane.

Hæmorrhagic infarction of the intestine resulting from obstruction of the mesenteric artery is an extremely interesting condition. In spite of the size of the mesenteric artery and in spite of the angle in which it leaves the aorta, which would appear to favor the entry of emboli into it, large emboli appear to be extremely rare. It is probable that small emboli frequently do enter the artery, but from the character of the circulation of the intestine and the abundant anastomosis which are found between the small branches of the artery, these small emboli produce no harm. The superior mesenteric artery is in no way a terminal artery in the sense of Cohnheim. There are numerous anastomoses, not only between the very small branches, but with the gastro-duodenal and inferior mesenteric. The area of tissue supplied by the artery, and the extreme length of the intestine are unfavorable for the development of a sufficient collateral circulation. In the dog, tying of the superior mesenteric near its origin always produced complete hæmorrhagic infarction of the intestine. The infarction is due to the entry of blood into the anæmic territory from the anastomoses above and below. It is remarkable that in the three cases which I show, the hæmorrhagic infarction should have been so slightly developed. In only one case, that from the Massachusetts Hospital, was it at all extensive. In the second case, although the entire artery was obstructed, there was only a beginning infarction in a small area of the intestine corresponding to the first embolus. In the first case it is probable that the thrombus of the aorta extending into the artery was not a totally occluding one. Only in this case was obstruction of the intestine a prominent clinical feature. It is probable that sufficient blood entered through the obstructed artery and through the anastomosis to preserve the integrity of the vessels sufficiently to prevent diapedesis and infarction, but not sufficient to provide the necessary enervation. It is important to know that obstruction of the superior mesenteric artery may give rise to paralysis of the intestine, obstruction and to peritonitis, and it is a condition which is beyond surgical interference.

LAMINECTOMY ELEVEN MONTHS AFTER INJURY TO THE SPINE.¹

BY WALTER B. PLATT F.R.C.S. (ENG.), BALTIMORE, MD.

MORE than twelve hundred years ago Paul of Ægina, that famous Greek physician, definitely proposed the operation of laminectomy after injury to the spine, in these words: "Wherefore, having first given warning of the danger, we must if possible attempt to extract by an incision the compressing bone, or if not, we must soothe the part by the anti-inflammatory treatment. But if any of the processes of the vertebræ of which the spine as it is called consists, be broken off, it will readily be felt upon examination with the finger; the broken piece yielding and returning again to its position, and therefore we must make an incision of the skin externally and extract it, and having united the wound with sutures, pursue the treatment for recent wounds."

Later, Albucasis also recommends that, when a piece of the spine is broken off and causing great irritation, an incision be made and the piece removed.

So great a period between the conception of an operation and its successful practical execution as exists in the case of laminectomy can scarcely be paralleled in the history of surgery.

We must not forget that eminent men have performed this operation again and again between that time and this, and that it was again and again advised as the right thing to do, while nearly always the result was fatal, apart from the mortality of the injury preceding the operation, in which other important structures and organs, notably the kidney, were damaged. Why the result was so fatal, we now know. It is an operation that can only succeed with the most perfect aseptic or antiseptic precautions.

Laurence Heister, Professor of Surgery in the German University of Helmstadt, writing in 1739, advises: "If in any case the spinal marrow should be divided, Death will generally be an inevitable Consequence. But to offer the patient no Assistance because we despair, would seem cruel and uncharitable; therefore we must try our Skill, though our Attempt should be in vain. In order to which, the Surgeon must lay bare the fractured Vertebræ with a Scalpel, and replace or else remove, such Fragments as injured the spinal-marrow. The Wound is afterward gently cleansed as usual, and dressed with the balsams . . . to be held on with the Napkin and Scapulary, till the wound Shall terminate either in a perfect Cure or Death."

In 1762 Louis removed fragments of the laminæ through a gunshot wound, and the man recovered with partial paralysis. This is, however, a very different matter from making an incision where no wound exists.

It is probable that Henry Cline, in the year 1814, was the first to do this (in other words, to do a laminectomy), and his patient died. For doing the operation he was severely condemned by his colleagues. Then comes a long list of laminectomies every one of which was fatal, each operator thinking that perhaps his method or the conditions in his case might admit of a good result.

There is a rather indefinite report of a case done by Dr. H. A. Potter, of Geneva, N. Y., where the patient survived. Hamilton ("Dislocation and Fractures")

gives a list of 14 operations by various surgeons all of which were attended by fatal results. Sir Astley Cooper ("Manual of Surgery," 1837) recommends the operation, but advises against it in the same breath. Hamilton, as late as 1875, tell us that "we are reluctantly compelled to declare that the expedient is scarcely worthy of a trial" ("Fractures and Dislocations").

Samuel Cooper ("Practice of Surgery," London, 1820), writes: "We read of incisions being made, and of the fragments of bone causing pressure on the spinal marrow being elevated or extracted; but what considerate surgeon would venture to imitate such practice." Bransby Cooper ("Surgical Essays," etc., London, 1843), in speaking of removing fragments of broken laminæ after an injury, by making an incision, says: "I believe there are cases which may warrant the importance of this operation, although at the same time I believe there are but few cases in which success is to be expected." Sir Benjamin Brodie ("Injuries of the Spinal Cord" in "Med. Chirurg. Transactions," London, 1837), says: "I am not aware that in any of the cases in which it has hitherto been performed the operation has been the means of preserving the patient's life or even of relieving any of the more important symptoms." Liston ("Practical Surgery," London, 1840), writes: "It has been proposed to make incisions on the broken bone to examine the extent of the fracture and displacement, and to attempt the removal of the pressure on the chord by trephining. . . . By these means, now generally and very properly looked upon as unwarrantable, effused blood could not be removed nor lacerations repaired, while the chance of inflammatory action would be much increased."

Gross, as late as 1862 ("System of Surgery"), writes: "Trephining will not be likely to be of any service; the operation has been tried in a number of cases of depressed fracture of the vertebræ, but in none has it ever been productive of any benefit."

Erichsen ("System of Surgery," "Science and Art of Surgery," 1872), in speaking of the removal of broken laminæ after spinal injury, writes: "But though so far the result has been but little satisfactory, ought surgeons to discard the operation? I think not."

Bryant ("Practice of Surgery," 1872,) mentions a successful instance of trephining by Gordon of Dublin, and adds one of his own where he removed the spinous process and laminæ of the fourth cervical vertebra, with recovery from the operation and decided improvement in motor power. The modern surgery of the spine is of but ten short years' duration, and most of the successful cases are within the last five years. Macewen, in 1883, did a laminectomy of three dorsal vertebræ, for complete paraplegia of two years' duration caused by angular deformity of the spine. The patient is said to have completely recovered (Treves, "Operative Surgery"). In June, 1888, Gowers and Horsley reported a case of the successful removal by laminectomy of a tumor from the spinal cord. Since then there have been a number of laminectomies reported, among them those of DeForest Willard, William White, Abbé, Burrell, Deaver, Dawbarn, and Richardson in this country, as well as Macewen, Lane, Wright and Duncan in Great Britain.

Dr. J. William White of Philadelphia and Dr. H. L. Burrell of Boston have made admirable reviews of the cases and results up to three years ago, when it is fair to believe that the technique of the operation was pretty well understood.

¹ Read at the semi-annual meeting of the Medical Chirurgical Faculty of Maryland, November 21, 1893.

The results in laminectomy, vary of course as to whether it is done immediately after the injury or some time afterward. Again, whether it is done for Pott's disease or for the removal of a tumor within the cord. Dr. William White has shown that out of 37 operations recently performed with antiseptic precautions, after fracture of the vertebræ, there were 6 complete recoveries; 6 were benefited, and recovered from the operation; 11 recovered, unimproved; and 14 died ("American Text-Book of Surgery"), a mortality of 38 per cent.

Careful observations show a very large per cent. of fractured laminæ in all cases of fractured spine. The pressure of the broken portions is often the exciting cause of secondary changes in the cord. This was probably true in the case now reported by me where the paralysis came on some three weeks after the injury. It is likely that the laminæ fractured at the time of the accident became displaced later and pressed upon the cord. It will be seen that operation was delayed until eleven months after the accident, and at least ten months after total paralysis, making the case a most unpromising one at the outset, both from the total long-existing paraplegia, and the extremely poor general condition. The operation was the only hope for the least benefit.

In the operations undertaken to relieve paralysis due to Pott's disease, the results have been brilliant. In one case where the paralysis of motion and sensation had existed for two years with paralysis of rectal and vesical sphincters, the boy was able (after five years) to play football. Laminectomy should never be done to relieve the paralysis of Pott's disease until the failure of all other approved methods of treatment, and the patient is steadily growing worse. Statistics show that over 80 per cent. of such cases recover without operation.

The mortality of laminectomies in traumatic cases, as stated by Chipault (*Revue de Chirurgie*, March, 1893), out of 160 cases, was 65, with 15 unknown results. He further states that in delayed operations after injury, myelitis sets in after two or three days, and after some weeks sclerosis of the cord; that delayed operations have never given satisfactory results, while early ones have nearly always had the contrary result.

We see then that in cases of broken back, instead of allowing the patient to die a miserable death, he should be operated on at an early date, and the compression removed, as is often possible by a laminectomy, when there is a good chance of, at least partially, restoring the patient to good health.

The patient J. L., white, thirteen years old, was admitted to the Garrett Hospital for Children, August 23, 1893, with the following history: In October, 1892, in coming down stairs the patient slipped, and in trying to recover his balance the back was bent sharply backward. In consequence of this, he suffered pain in the spinal column, which pain persisted. Two weeks later he fell from a car, striking his side upon a curbstone. One week later, while walking along the street the patient was suddenly seized with peculiar sensations in his legs and abdomen—tingling and numbness. This was accompanied by weakness of the lower extremities, whereupon he went to bed. In three days there was complete paralysis of motion and sensation as high as the margin of the ribs. Four days later loss of control of the bladder and rectum was

noted. One month after taking to bed, that is, about seven weeks after injury, a long, round curvature appeared in the dorsal region. The first bed-sore was over the sacrum, and this occurred about the end of December, 1892.

On entrance to the hospital, August 23, 1893, the patient exhibited the following physical signs: Anæmic, emaciated. Had a tight cough, no expectoration. Night-sweats present. Afternoon temperature 102.2°; pulse 128; respiration 32. Marked anterior posterior curvature of spine, from sixth to tenth dorsal vertebræ. The vertebral spines in question could not be felt by reason of the general thickening over the whole region. There was considerable swelling laterally, marked on the right side, where there was also some rise of temperature superficially. Tenderness and œdema, but no fluctuation. The swelling occupied the entire interscapular region. Scapula stood out prominently. There was dulness on percussion on the right side of the chest below the nipple in front, extending into the axillary region, and nearly all over the back. Loud pleuritic friction-sounds could be felt and heard over the right back posteriorly, below the scapula. The skin over the paralyzed region was dry, shiny and desquamating. Small, round, fecal masses could be plainly felt along the tract of the ascending colon. There was complete paraplegia, both motor and sensory. There was great wasting of all the muscles in the paralyzed area. The paralysis extended as high as the line of the tenth rib behind, and one inch from the costal margin in front. There was a wide zone of hyperæsthesia immediately above the line of paralysis. There was a line about one inch wide below the hyperæsthetic zone, where sensation was dulled, but not absent. Below this paralysis was complete. Entire loss of control over sphincters of bladder and rectum. There were seven or eight bed-sores, some large, some much smaller. They were situated over the sacrum, trochanters, heels, and over the right fibula below, etc. The pleuritic friction-sound rapidly diminished, and finally disappeared after four or five days. There was never any pus or discharge from the back, except such as arose from the bed-sores.

OPERATION, SEPTEMBER 6, 1893.

The patient being etherized, two longitudinal parallel incisions were made, one on each side of the dorsal spine, five inches long, extending from the fourth to the ninth vertebral spines. These were connected at the top by a transverse incision after the completion of the others, and after the hæmorrhage had been checked. The latter was abundant and of very dark blood.

The longitudinal incisions were made just to the inner side of the transverse processes, which were with difficulty made out, with the patient in the semi-prone position; the planes of the incision were directed toward the median line as well as downward. The hæmorrhage was checked by pressure with pads of sterilized gauze, thrust into the wounds. The interspinous ligament was now divided at the bottom of the transverse incision, and the laminæ of three vertebræ, the fifth, sixth and seventh, divided close to the transverse processes by oblique-cutting forceps. A number of loose fragments of laminæ were felt and removed when the longitudinal incisions were first made. The flap, consisting of skin, muscle, ligaments and bone, was turned downward, exposing the dura mater of the

cord. All pieces of bone which could be felt in the reversed flap were now detached from their connections. The pieces were irregular in outline, and evidently remnants of partially absorbed laminæ and spines. The dura was exposed for a distance of four inches. It appeared to be perfectly healthy, and was not therefore opened. The spinal canal above and below the seat of operation was smooth, and of normal calibre. The dura was pale blue in color, not thickened externally, neither was there any pus or exudation seen anywhere in the course of the operation.

The flap was now replaced, and stitched in place by a number of silkworm-gut and a few silk sutures. These were for the most part inserted as deeply as possible. No arteries required ligature. A rubber drainage-tube was inserted at each outer, upper angle of the wound. Iodoform gauze, sterilized gauze, and absorbent cotton were applied, and the whole kept in place by a gauze bandage.

The operation lasted one hour and twenty minutes. During the night the patient seemed very weak, but reacted well considering his exceedingly feeble state; and the day following he seemed but little weaker than before the operation.

September 11th. Patient has some cough, but is steadily gaining in strength each day.

September 12th. Yesterday patient complained of his toes feeling cold and as if electricity were passing through them. Nine centimetres above umbilicus he has skin sensation. Deep pressure can be felt much lower down. Touching skin just above the totally paralyzed area excites reflex movements of opposite left (right) hand. Pressure in right hypochondrium excites immediate pain in the left. Bed-sores looking better. There is occasionally a faint, dry cough.

September 13th. Said he felt the catheter when it was passed.

September 14th. Seven sutures removed, some pus about stitches.

At the present date (November 21) the patient is as emaciated as before. The bed-sores have nearly all healed a great deal since the operation. Some are entirely well. The patient, as a rule, eats with an excellent appetite. He can now lie on either side with comfort, something impossible before the operation. There is no perceptible gain in skin sensation. The anæsthesia (to touch) is as marked as before the operation. The patient is, however, considerably more sensitive to abdominal pressure, and much more so to the stimulation of the faradic current. He now feels the faradic current in both thighs, legs and feet, when applied over the tracts of the large nerves with firm pressure. Application of the current to one limb will often cause decided sensation in the opposite limb. Wherever the current is applied, whether to thigh or leg, patient complains of feeling the current in the feet. There is absolutely no contraction of any muscle below the paralyzed area to any amount of faradic stimulation. The lines of operation are entirely healed, with the exception of a small granulating surface at one upper angle one-quarter of an inch in diameter. There are no sinuses left after the operation. Patient sits propped up in bed a few minutes at a time without undue fatigue.

The net result of the operation at the time of writing this paper, may be stated to be: No improvement whatever in motion since operation, some decided increase in sensitiveness to faradic stimulation, healing

of bed-sores to a considerable extent. The patient is able to lie on either side for a time without fatigue, something impossible before, although he was in the hospital two weeks before operation. He has apparently reached a standstill in improvement in his general condition. He no longer has night-sweats.

I was never able to convince myself of the existence of tuberculosis of the lungs. He has had the most careful nursing, and the most generous diet that he could take, wine and whiskey being allowed with his meals. When his temperature rose he was immediately put upon a suitable diet. One four-hundredth of a grain of atropia at night will control the sweats perfectly, as we repeatedly determined. He has always been catheterized twice daily, and the bladder washed out when urine became turbid or ammoniacal.

In performing the operation the following points were noted:

The copious venous hæmorrhage, controlled by pressure with pads of sterilized gauze wrung out of hot boiled water.

The unusual retraction of the skin, which rather assisted than acted as an obstacle in carrying out the operation.

The difficulty in dividing the laminæ, and the care that had to be used in keeping within the transverse processes so as not to go wide of the objective point.

The operation is considerably easier on the living than on the cadaver, on account of the bowing of the back usually present in the patient, and the comparative wasting of the muscular substance.

With ordinary care there is little danger of wounding the spinal cord.

The cutting bone-forceps should be directed well inwards, so as to divide the laminæ at a right angle to their axes.

We are not only justified in considering, but we are bound to regard laminectomy of the spine in the same way as we do trephining of the skull, that is to say, the mortality of the operation after an injury is to be attributed in large part to the injury which is the occasion of the operation, and not to the operation itself.

As in trephining the skull, the mortality should be reckoned by the number of deaths occurring when performed for disease. The mortality should, moreover, be distributed according to groups; for example, the number of deaths after an operation to remove broken or displaced laminæ might be widely different from a laminectomy to relieve pressure of an exudation between the laminæ and the bone, or for hæmorrhage without or within the dura, etc. No useful purpose or rules for guidance can be formed by grouping unlike cases together. As in skull-trephining after accident, the bad results after spine trephining are largely due to the laceration of the nervous substance which may be injured, beyond any possibility of repair, by the force of the blow constituting the accident — not due to the surgical operation, but in spite of it.

A large portion of the back of a cadaver was here exhibited, showing the facility with which a sufficiently large section of the cord may be exposed without loss of substance; the ease of replacing the flap which was turned down; the depth below the surface of the latter, reminding one strongly of the railroad at the bottom of a "cut." The disadvantages of this operation were also shown, there being two long incisions instead of one to heal, twice as many vessels divided, and the muscles close to the median line cut transversely above.

Practically I do not believe these objections in any degree important.

FURTHER HISTORY.

The patient seemed to be gradually losing strength the first week in December. He was taken home (five hours by rail) against advice, by his father, December 24th, and died December 31, 1893, 116 days after the operation. This was one of those cases where there was reason to fear a total transverse lesion of the cord; but as the operation offered the only hope of relief, it was performed. No autopsy was obtained.

Clinical Department.

CLINICAL NOTE-TAKING, WITH A LIST OF FOUR HUNDRED AND NINETY-ONE MEDICAL CASES SHOWN TO THE THIRD CLASS OF THE HARVARD MEDICAL SCHOOL.¹

BY ELLIOTT P. JOSLIN, A.B., PH.D.,
Harvard Medical School.

MANY advantages accrue from note-taking at a clinic, but for these notes to be of permanent value to the student they must be accessible. With this end in view the following method has been adopted by the writer.

The record of each patient was taken on a separate sheet of paper. At the head of the sheet was printed

Diagnosis	Sex	Married	Single	Age
Duration				
Name				
Residence				
	Occupation			

If the case required more than one sheet, blank slips of the same size were used, and the pages numbered. This allowed easy insertion of subsequent reports of the progress of the individual. The same plan allowed a ready classification, since all the notes were turned into a card catalogue by a simple grouping of cases. These were arranged in a box with index cards of appropriate size denoting the various diseases. As a result, a student can have at the end of his course a very serviceable text-book of medicine, containing the teachings of several clinicians emphasized by and based on what he has himself seen. How valuable this "text-book of notes" may be, can be judged from the following list of cases which were shown by Drs. R. H. Fitz, F. C. Shattuck, A. L. Mason and H. F. Vickery at the Massachusetts General and City Hospitals. The list covers a period of about twelve school-year months, and represents the cases seen by one member of the present third class of the Harvard Medical School.

SPECIFIC INFECTIOUS DISEASES.

Typhoid fever 21, vaccination 1, mumps 1, influenza 3, sequelae of diphtheria 2, malaria 7, syphilis 7, tuberculosis of lymph glands 3, tuberculosis of lungs 10, tuberculosis of peritoneum 3, tuberculosis of meninges 1, general tuberculosis 3. Total, 71.

CONSTITUTIONAL DISEASES.

Rheumatic fever 2, chronic rheumatism 6, pseudo-rheumatic affections 4, muscular rheumatism 2, arthritis deformans 3, gout 2, diabetes mellitus 12, rickets 4. Total, 84.

DISEASES OF THE DIGESTIVE SYSTEM.

Stomatitis 1, chronic tonsillitis 2, cancer of the œsophagus 1, gastric catarrh 1, dyspepsia 2, nervous vomiting 1, dilatation of stomach 3, gastric ulcer 2, gastric cancer 11, diarrhoea 1, appendicitis 11, intestinal obstruction 1, constipation 1, catarrhal jaundice 4, gall stones 7, cirrhosis of liver 13, abscess of liver 2, neoplasm of liver 2, dislocation of liver 2, hypertrophy of spleen 1. Total, 74.

¹ Read at a meeting of the Boylston Medical Society, April 12, 1894.

DISEASES OF THE RESPIRATORY SYSTEM.

Acute bronchitis 1, chronic bronchitis 4, bronchitis and emphysema 3, bronchial asthma 5, partial occlusion of bronchus 1, œdema of lung 1, acute fibrinous pneumonia 13, chronic interstitial pneumonia 2, emphysema 1, gangrene of lung 1, abscess of lung 1, acute pleurisy 13, chronic pleurisy 8, cancer of pleura 1. Total, 62.

DISEASES OF THE CIRCULATORY SYSTEM.

Pericarditis 4, endocarditis 2, chronic valvular disease 34, hypertrophy and dilatation 4, myocarditis 4, neuroses of heart 1, arteriosclerosis 3, aneurism 5, phlebitis 2, abnormal position of pulse 1. Total, 63.

DISEASES OF THE BLOOD AND DUCTLESS GLANDS.

Secondary anemia 5, chlorosis 4, progressive pernicious anemia 2, leukæmia 8, pseudo-leukæmia 6, goitre 2, exophthalmic goitre 7, myxœdema 2. Total, 36.

DISEASES OF THE KIDNEYS.

Hyperæmia 1, floating kidney 6, paroxysmal hæmoglobinuria 1, chyluria 1, acute nephritis 7, chronic nephritis 10, renal calculus 4, tumors 2, perinephritic abscess 1, incontinence of urine 1, cystitis 1. Total 41.

DISEASES OF THE NERVOUS SYSTEM.

Neuritis 11, Menière's disease 1, scoliosis 3, diffuse myelitis 1, ascending lateral degeneration 1, descending lateral degeneration 1, locomotor ataxia 7, compression of spinal cord 1, cerebral meningitis 2, aphasia 1, hemiplegia 13, insular sclerosis 1, general paralysis of the insane 2, brain tumors 3, chorea 6, epilepsy 5, migraine 1, occupation neurosis 1, hysteria 2, neurasthenia 4, hemianæsthesia 1, acromegalia 1, scleroderma 1, melancholia after delivery 1. Total, 78.

DRUG POISONING.

Alcoholism 4, opium 2, lead 10, arsenic 2, tobacco 2, illuminating gas 2, acconite 1, copalbe 1. Total 24.

MISCELLANEOUS.

Tumors 8, sexual impotence 1, debility 2, elephantiasis 1, "chronic unemployed" 1. Total 13. Total number of cases shown, 491.

Medical Progress.

RECENT PROGRESS IN SURGERY.

BY H. L. BURRELL, M.D., AND H. W. CUSHING, M.D.

Concluded from No. 16, p. 387.

TRAUMATIC ANEURISM OF THE VERTEBRAL ARTERY.

Matas¹⁷ records a case of aneurism of the vertebral artery, which was cured by extirpation of the sac. The author concludes: "That in certain favorable cases of traumatic aneurism in the upper and more superficial part of the vertebral artery, recovery without operative interference is possible. In every case when the danger of rupture of the sac is not immediate, good results may be expected, if only as adjuvants to future radical treatment, from the systematic application of cold and pressure to the sac, or digital pressure over the artery below the carotid tubercle. In most cases there is a tendency in the aneurism to progress rapidly to rupture, such tendency being often favored by the increased tension caused by ligature of the carotid trunks under mistaken diagnosis. This error may always be avoided by carefully observing the effects of temporary compression of the carotid on the circulation in the tumor. Free exposure of the bleeding region and temporary plugging have hitherto given the most satisfactory results. The use of coagulant injections is especially to be condemned. In the extremely rare cases of idiopathic cervical aneurism, and in circumscribed traumatic aneurisms situated high up in the posterior triangle, proximal ligature might be attempted with some prospect of success, especially if cold pressure and rest be resorted to as adjuvants in the treatment. In aneurisms situated low down in the posterior angle, the Hunterian operation will almost certainly fail, as it will be found impossible to reach the trunk of the

¹⁷ *Annals of Surgery*, November, 1893; *British Medical Journal*, December 9, 1893.

artery without involving the sac in the incision. When in a case of an aneurism well circumscribed and situated high up in the neck, the ordinary local treatment has failed and it has been decided to open the sac, it is justifiable to expose the vertebral artery below the anterior tubercle of the sixth cervical process, and to compress the vessel until its wounded part has been definitely secured at the bottom of the aneurismal cavity. In the management of non-aneurismal wounds of the vertebral artery, the surgeon should apply the same treatment as in cases of traumatic aneurisms in this vessel. In some rare cases, however, and especially in gunshot injuries through the mouth, in which more than one vessel may be injured, a direct attack on the bleeding point is impossible. As plugging through the mouth is impossible, the only hope for the patient lies in the immediate but provisional control of both the common carotid and vertebral arteries of the same side, with a view of cutting off the entire arterial supply from the injured region. After the precise seat of the hæmorrhage has been deliberately made out, the definitive ligature may then be applied to either of the exposed arteries, or to both, if necessary. In the more common cases the difficulties in applying direct pressure to the bleeding point are less in the upper part of the neck than in the lower part where the artery is surrounded by vital structures."

A MODE OF CONTROLLING THE CIRCULATION THROUGH THE ABDOMINAL AORTA.

William McEwen¹⁸ suggests a method which he has used for the last fifteen years for controlling the abdominal aorta. It is as follows:

"As the patient lies on his back on the table, the assistant, facing patient's feet, stands on the left side of the table in a line with the patient's umbilicus. He then places his closed right hand upon the patient's abdomen, a little to the left of the middle line, the knuckles of the index finger touching the upper border of the umbilicus, so that the whole hand will embrace about three inches of the distal extremity of the aorta above its bifurcation. The assistant, then standing upon his left foot, his right foot crossing his left and resting upon the toes of the right—an attitude commonly assumed by public speakers—leans upon his right hand, and thereby exercises the necessary amount of pressure. With the index finger of the assistant's left hand, the weight necessary for the purpose can easily be estimated by the effect produced upon the flow of blood through the common femoral at the brim of the pelvis. Whenever the flow of blood through the femorals is absolutely arrested the abdominal aorta is sufficiently controlled, and no further weight ought to be applied.

"The weight exercised can be varied at will by increasing or decreasing the angle which the assistant's body makes with the floor. The position which the assistant assumes relatively to the patient is represented in the accompanying photographs.

"As the abdominal aorta sometimes bifurcates higher than usual, before the operation is commenced a trial of the effect of the pressure at the part selected ought to be made, testing the result of pressure on both femorals. When *both* are equally controlled, the bifurcation occurs below the point pressed on; when only one is controlled the hand requires to be placed on a more proximal part.

¹⁸ *Annals of Surgery*, January, 1894.

"As there is no direct muscular effort required in maintaining the pressure further than the preservation of the equilibrium, the position can be maintained by the assistant without undue strain on his part, and without shifting his hand for at least half an hour, a time amply sufficient for the performance of most operations requiring the control of the circulation through the abdominal aorta."

SUTURE OF NERVES.

Gneiss¹⁹ reports eleven cases of nerve-suture at Brun's clinic. Four were cases of primary operations, and seven secondary. The following nerves were sutured: the median, five times; the ulnar, three times; the radial, four times; the perineal nerves once. All but one operation was successful. An interesting point of the report is the description of Brun's technique. In the cases of primary operation the ends were united at once; in the secondary cases the ends were usually refreshed and the cicatricial mass removed. One case, as shown by illustration, was treated by making a slit in the nerve trunk, which split the cicatrix and extended into sound nerve tissue; the ends of the cut were then approximated so that the sides were brought in contact, and the line of incision at right angles to the long axis of the nerve trunk. Sutures passed through these lateral projections secured the nerve in its new position. Catgut was the material used for suture. In four cases the nerve was protected from pressure during healing by a decalcified bone tube. The article is a valuable one, and contains many interesting details.

SUPPURATIVE TENO-SYNOVITIS.

Tollemer and Macaigne²⁰ relate a case in a man aged nineteen. On the fifth day of the gonorrhœa he had pain and swelling in the small joints of the left hand. On the fourteenth day the right hand, and chiefly the tendon of the index finger, were affected. Here a lymphangitis also appeared. The pus was let out, and movement was eventually completely restored. The tendon of the left little finger also became involved. The inflammation was here adhesive only, and the tendon remained adherent to the sheath with limitation of movement. In the above-named pus, a micro-organism—proved to be the gonococcus (1) by its form, (2) by its presence in the cells, and (3) by its decolorization by Gram's method—was found in pure culture. Cultivation experiments were also made. There is now no doubt that gonorrhœa may assume the character of a general disease. The micro-organism has rarely been found in the articular serous effusions, but the negative results may be due to its rapid disappearance. There was practically no fever during the whole of the illness. Owing to the limited vitality of the gonococcus, the suppuration seems to end as soon as the pus is let out.

MALLET FINGER.

Robert T. Morris²¹ describes a condition which he states is not uncommon among men engaged in athletic sports. The injury consists, not in a bodily separation of the tendon from its points of attachment, but rather in a thinning of the tendon cephalad from the principal point of attachment to the phalanx, and from

¹⁹ *Beiträge zur Klin. Chir.*, 1893, Bd. x, Heft 2.

²⁰ *Rev. de Méd.*, November, 1893; *British Medical Journal*, December 16th.

²¹ *Medical News*, September 9, 1893.

the fibres that form the posterior ligament of the last phalangeal articulation. A few fibres of the tendon are undoubtedly ruptured, but most of them slide away from each other very much as the threads of a textile fabric separate when the fabric is violently stretched, but not torn, the structure retaining its original general appearance.

Immediately after the occurrence of the injury to the tendon, the last phalanx of the finger assumes a semi-flexed position, and the deformity is usually permanent, the extensor tendon then having little or no influence upon the freed phalanx. Aside from the uncanny appearance of such a finger, the deformity is a source of annoyance to the patient.

The tendon is repaired without much difficulty by making a longitudinal incision two centimetres in length over the site of the injury, dividing the thinned tendon longitudinally into the two principal fasciculi into which it naturally separates, dividing the tendon cephalad transversely from the thinnest point, and advancing each fasciculus to a point upon its own side of the finger, near the base of the finger-nail. At this point the fasciculus is sutured to the under surface of the skin rather than to the periosteum and tendinous remains, because the former structure affords a firmer hold; and the cut end of the tendon makes as good a union with the phalanx as it would if sutured directly to the periosteum.

TREATMENT OF TUBERCULAR COXITIS BY IODOFORM INJECTIONS.

C. Bunker²³ considers this method advantageous, and recommends Kenster's technique. He injects into the hip-joint through a puncture made at a point (the inner border of the sartorius) in a horizontal line drawn from the femoral artery where it crosses the pubic bone to the trochanter. The injection is made with a hypodermic syringe having a needle five to seven centimetres long. Two and one-half grammes of a twenty-per-cent mixture of iodoform and glycerine are injected every eighth to fourteenth day.

OSSIFYING HÆMATOMA.

Arsdale²⁴ has reported a case occurring in a man twenty-two years of age, who had a severe contusion on the right arm, just below the insertion of the deltoid. When first seen a fluctuating tumor was there. At the end of six weeks a tumor of bony hardness was present. Aspiration having failed, it was decided to remove the tumor. This was done, and the patient was discharged cured. The function of the arm at the end of two years was perfect. The points of interest in this case are that an ossifying hæmatoma may be readily confounded with an osteoma, periostitis, myositis ossificans and osteosarcoma.

SOME POINTS OF PRACTICAL IMPORTANCE IN THE USE OF CURVED SKIN INCISIONS.

In an interesting article, Peyton T. B. Beale²⁵ has summarized the advantages of curved over straight incisions wherever the former is practicable.

"(1) It heals more rapidly, and for these reasons: there is really only one edge of the wound, that belonging to the flap, that is movable, the other edge being still adherent to the subjacent tissue; moreover, the flap having been stitched to the neighboring skin

or held well away from the seat of operation, both edges of the wound are quite uninjured by the time the sutures are inserted. (2) The resulting scar is smaller, though this is only of importance in certain parts, for the skin may be incised obliquely in making a curved incision, so that the epidermis on the edge of the flap is slightly in advance of the true skin. (3) It fully exposes the part to be operated upon, assuming that the base of the flap is twice or three times its length, and gives the operator plenty of room in which to work. (4) Suturing the edges is easier than in the case of a straight incision, especially if the skin be pricked in one or two situations exactly opposite to one another before the incision is made, and more often the curved wound is adapted to the shape of the part than a straight one. (5) The resulting cicatrix is not over the seat of operation. (6) Drainage is often most perfect by inserting a tube through an incision in the base, or some part of the flap, thus giving no hindrance to the primary union of the incision, and preventing any possible discharge from infecting the edges. (7) Incision through inflamed or diseased skin may be avoided, and yet the disease is easily reached. (8) There need be no tension on the edges of the wound, as the flap of skin is, so to speak, loose, and if there is fear of tension, a silk suture can be passed through the base or some part of the flap and out again, and then through the skin on the other side of the incision, and there fixed, thus avoiding a long suture beneath either edge of the wound. I think that the form of skin incision, its subsequent result to the patient, and its immediate results to the surgeon during the progress of an operation, are matters often neglected, and not sufficiently considered before the operation is undertaken, and I feel sure that there are many points of interest connected with the subject."

BLOODLESS AMPUTATION AT THE HIP-JOINT.

Dr. John A. Wyeth²⁶ reports 40 cases operated upon by his method. This is undoubtedly one of the best methods we have for controlling hæmorrhage in this formidable operation. He says: "Without discussing statistics, I claim it safe to conclude that by the method given bleeding after hip-joint amputation is as safely and surely controlled as for an amputation of the thigh lower down. In no single case has it failed, and it has been employed by operators of all grades of experience. The 40 cases are divided as follows: sarcoma, 17 (mortality, 11.76 per cent.); inflammatory bone disease, 18 (mortality, 16.6 per cent.); violence, 4 (mortality, 100 per cent.); nerve injury, 1 (mortality, —); for disease, 36 (mortality, 13.88 per cent.); for injury, 4 (mortality, 100 per cent.); giving a total death-rate of 22.5.

SACRAL OSTEO-PLASTIC OPERATIONS.

Czerny's²⁷ report at the last meeting of the German Surgical Congress, in which he describes the removal of intra-pelvic tumors by the sacral route, is a very interesting one. It describes in detail numerous operations performed for the removal of such neoplasms, and is too long to give more than the writer's conclusions. An excellent abstract has been published, however, by Warbasse.²⁸ Czerny thinks that the sacral method of operating on intra-pelvic tumors will

pass through the same stages as the sacral extirpation of the rectum. It was at first received with indifference or reserve, then practised too enthusiastically, but gradually has taken its proper and legitimate place, and is considered an operation of value in selected cases. He also thinks the sacral route is the shortest to the parametrial region for the enucleation of paracervical myomata, or similarly situated growths.

ON THE ADVANTAGES OF THE STEEL SCREW IN THE TREATMENT OF UNUNITED FRACTURES.

W. Arbuthnot Lane²⁸ suggests the use of steel screws in immobilizing ununited fractures. He speaks of the difficulty of retaining the saw surfaces in position by means of silver wire, and believes that the two following conditions must be complied with to ensure success:

"(1) The surgeon must not be satisfied with removing a thin surface of bone on each side of the fibrous ankylosis, but a good, thick slice must be taken off the end of either fragment, so as to expose the normal structure of the shaft. It would seem that the bone in the immediate vicinity of the acquired amphiarthrodial joint undergoes such vascular changes as interfere with its taking an active share in the formation of callus and bony ankylosis of the fragments. If a thick slice of bone, which has been sawn off one of the fragments in such an operation, is divided vertically, the bone in immediate relation with the false joint will be found to be dense and comparatively evascular, and this condition will be found to extend for an unexpected distance into the shaft. Therefore, in order to obtain bony union with any certainty, it is necessary to sacrifice a considerable portion of the length of the limb, and the amount of bone removed from each fragment must bear a direct relationship to the duration of the interval that has elapsed since the injury. Such operations are sometimes the most difficult in surgery, especially when performed for ununited fracture of the tibia in its upper third. The difficulty is sometimes greatly increased by the necessary removal of a portion of the fibula, this bone not having been broken at the same time as the tibia, or, if it had been, union had ensued in it. Such conditions of non-union of fractures in the leg are, in my experience, always the result of the application of the principle of the vertical foot-piece, and I trust that, since the fallacy of that treatment has been satisfactorily exploded, surgeons will not have to deal with such difficult cases in the future.

"(2) The recently sawn surfaces of bone must be retained immovably in accurate apposition. I have frequently found the greatest difficulty in retaining the freshly sawn surfaces of bone in accurate and firm apposition by means of the silver wire, for the reason that the oblique sectional planes presented by the fragments are in different vertical levels, and tend, when fastened together with wire, to separate vertically, however firmly they may be clamped together during the boring of the holes, and however great the strain exerted on the wire during its fixation in position. Again, the circumstances are quite different from those present in a recent fracture, where, as is well known, if sufficient care and trouble are taken, the broken surfaces will correspond exactly. In the case of the ununited fracture, the plane of the fracture is often only to be guessed at, since it has been much

modified by the formation of callus, etc. I have been much disappointed on several occasions, on cutting down on cases of ununited fracture in which an operation had been performed without success, to find the loop of wire lying comparatively loose in the bones. I therefore determined to try what I could do by using screws instead of wire, and then found that I was able to bring and to retain the opposing surfaces of bone into most accurate and forcible apposition by means of this powerful instrument. The use of two screws is much more advantageous than one alone, for the reason that any rotation of the bony surfaces around the screw as an axis is completely obviated. The screws produce no irritation whatever, and do not require to be removed. I should have found some of these operations impracticable but for Gowan's osteotome, which is an invaluable instrument under the circumstances. With it, one is enabled to ensure accuracy of parallelism in the sectional planes with a minimum of damage to adjacent vessels (a matter occasionally of no little importance), and by using the clamp portion of the instrument without the saw, the cut surfaces can be held firmly and immovably in apposition during the boring of the holes and while the screw is being driven in. It is well to remember that it is by means of the final turns of the screw that firmness and accuracy of apposition are obtained."

SEPARATION OF THE LOWER FEMORAL EPIPHYSIS.

Mayo Robson²⁹ directs attention to this accident, which is usually the result of direct violence. Shortening the projection of the diaphysis in the popliteal space, and of the epiphysis anteriorly, combined with the interference in the circulation, are the physical signs present. If there is any difficulty in reduction an anæsthetic should be used and the tendo-Achillis divided. A weight and pulley are needed in the after-treatment. If the large vessels are ruptured and gangrene supervenes, of course amputation is necessary.

TREATMENT OF GUNSHOT WOUNDS OF THE ABDOMEN.

Von Braman³⁰ has reported eight cases of gunshot wound of the abdomen, and has been led to form the following conclusions: (1) In all cases of gunshot wounds of the abdomen in which signs of injury of stomach or intestine, or of profuse internal bleeding, are presented immediately after the injury, prompt laparotomy is imperatively indicated. (2) The operation is especially indicated in every case in which the direction taken by the bullet leads not only to a probability, but even to a possibility, of the existence of a wound of the stomach. In 90 per cent. of cases of such injury to the stomach, death is inevitable under any plan of expectant treatment. (3) When undetected, laparotomy should be performed as soon as possible in cases of gunshot wound of the abdomen, as the prognosis becomes more and more unfavorable after every hour, and — particularly as a result of septic perforation — peritonitis is very bad indeed after an interval of twenty-four hours. (4) The indications for laparotomy thus furnished by the results of abdominal gunshot wounds in civil practice are still more imperative in the practice of military surgery. (5) Hæmorrhage caused by gunshot wounds of the liver and spleen should be assisted by plugging after laparotomy. (6) Operative interference and extirpation

in cases of gunshot wound of the kidney are indicated only by profuse and persistent bleeding. (7) Lateral wound of the ureter may heal spontaneously; complete division, however, indicates stitching, and in case of failure of this plan, nephrectomy. (8) Gunshot wound of the bladder should invariably indicate suprapubic section and closure of the wound by sutures, and the retention during the healing of a urethral catheter.

Reports of Societies.

THE OBSTETRICAL SOCIETY OF BOSTON.

CHARLES W. TOWNSEND, M.D., SECRETARY.

MEETING February 10, 1894, the President, DR. CHARLES M. GREEN, in the chair.

DR. F. MINOT read a paper entitled

OBSERVATIONS ON CASES OF FIBROID TUMOR OF THE WOMB.¹

DR. J. B. AYER spoke of a case that had formerly serious hæmorrhages. She is now forty-eight years old and the hæmorrhages have practically ceased, although he was called to see her about a year ago for retention of urine. He could recall other cases where the symptoms improved but the tumor remained of the same size.

DR. W. H. BAKER said he was much interested in the paper and thought it was very unusual for nearly one third of the cases to be between twenty and thirty years of age. The youngest case he could recall was twenty-three years old. Retention of urine he had found to be rather rare, as the bladder can usually accommodate itself to the growing tumor. As regards pregnancy, he had found that the fibroids increase very rapidly in size during the pregnant state, while after delivery they diminished very rapidly and sometimes disappeared, the process of involution extending to the tumors.

DR. F. MINOT mentioned a case of spontaneous expulsion of a fibroid tumor without any immediate unpleasant effect. In a few weeks the patient began to cough, became tuberculous and died in a few months. In another case, after a severe hæmorrhage, spontaneous expulsion of a large fibroid tumor took place.

DR. W. L. BURRAGE said that in his experience these tumors, as a rule, cause comparatively little interference with micturition. They occasionally cause inflammation in the pelvis which clears up; as regards their effect on the rectum, chronic and obstinate constipation often occurred. The cases Dr. Minot reported of absence of hæmorrhage for a long period were particularly interesting.

DR. F. H. DAVENPORT had seen but few patients with vesicle trouble due to fibroids. One was a case of multiple fibroid tumor he had seen to-day who has occasionally had retention of urine needing the catheter. In another case there was slight hæmorrhage from the bladder. He found here a small fibroid projecting from the anterior wall of the uterus and pressing against the bladder. On raising the uterus the hæmorrhage ceased.

DR. A. WORCESTER said he had heard a good deal said on the necessity of operating on every case of fibroid of the uterus. He wished he could feel that the operation was a safe one. He had watched patients who have carried fibroids for years, cases that had been handed down to him from other physicians. One is a lady of fifty years who has been cognizant of the tumor for twenty-five years. The tumor is so large it rises above the umbilicus and seems like preg-

¹ See page 405 of the Journal.

nancy at full term. She menstruates regularly, and has never suffered from menorrhagia or dysmenorrhœa; in fact, she is perfectly well and is able to do an immense amount of work. Another case, which had also been handed down to him, was supposed to have a fibroid tumor before 1855. She has never been ill with it, but a short time ago it began to increase in size. Dr. Homans saw it, and found it to be not a fibroid but an ovarian tumor, and removed it. Another case had a fibroid as large as an orange on the right side of the uterus, very prominent during pregnancy. After delivery she made a poor recovery, complaining of pains in the pelvis, an enlarged ovary being found. The ovary was removed by laparotomy, and the fibroid was found to have nearly disappeared, having decreased to the size of the thumb.

DR. GREEN recalled one case in which a large fibroid was spontaneously expelled: the tumor was about as large as a fetal head. The patient had previously declined operative treatment, and was given ergot, tampons being occasionally used to control hæmorrhage. He had seen five or six cases in which labor was complicated by the presence of a fibroid tumor: where the tumor is seated low, perhaps filling the pelvic cavity, it may obstruct labor and necessitate abdominal delivery of the child or embryotomy; but in each of the cases he had seen the tumor recede, as labor advanced, and the child was delivered either spontaneously or by the aid of forceps. When the tumor is seated somewhat higher, it may interfere with the ordinary mechanism of labor; or, what is more serious, it may interfere with the retraction of the uterus. If, by chance, the placenta is attached wholly or in part over the tumor, serious and even fatal hæmorrhage may result. In regard to the subsequent shrinkage in fibroid tumors after pregnancy, he thought that usually the tumor involuted with the uterus: such was the case in two patients he had seen within a year. In one of these cases, which was in the Boston Lying-in Hospital, at the beginning of labor the tumor entirely filled the pelvis; but it receded, and the child, which presented the breech, was extracted alive without especial difficulty. The uterus and tumor both involuted, and at the conclusion of convalescence the tumor had shrunk to such a degree that it would scarcely have been detected without careful examination. Dr. Green thought that it was well to remember in these days of operative zeal that fibroid tumors very often not only do not grow rapidly but even remain stationary for years. He had seen a case the day before which he had observed for four or five years: the tumor, which was sub-peritoneal, reached nearly to the umbilicus; but he had been able to detect no change in size during the time mentioned. The patient was forty-seven years of age, and there was reason to hope that with the menopause so near at hand there might be no further increase in the tumor. At present, certainly, there was no indication for operative treatment, as there was neither pain nor hæmorrhage, and the patient was inconvenienced only by the weight of the tumor.

DR. EDW. REYNOLDS said he had watched a fibroid grow to the size of a mandarin orange in the second pregnancy and then dwindle to the size of the little finger. In the third pregnancy it grew to the size of two clenched fists, and is now, six weeks after delivery, growing small again. He had observed this same thing in another case.

He had seen six cases of labor complicated with fibroids, all of which did well eventually. One had severe post-partem hæmorrhage; one had a very difficult face presentation, owing to the fibroid; but these were the only cases in which there was any difficulty.

DR. A. D. SINCLAIR mentioned a case where a fibroid the size of a fist disappeared after confinement.

DR. F. H. DAVENPORT read a paper on

THE NON-SURGICAL TREATMENT OF CHRONIC PELVIC INFLAMMATIONS AND THEIR SEQUELÆ.¹

DR. W. H. BAKER said he would rather be asked to speak on the surgical side, but as that was ruled out by the paper he would quite agree with the method of Dr. Davenport, which puts the matter within the hands of the general practitioner and enables them to do good work.

DR. G. HAVEN said he would fully agree with Dr. Davenport in the value of the treatment by massage.

DR. A. D. SINCLAIR said that glycerine, ichthyol, and massage were three very important things. Their proper application took time, but the results were good.

DR. A. WORCESTER would emphatically endorse massage.

DR. EDW. REYNOLDS reported a

CASE OF EXTRA-UTERINE PREGNANCY

and showed specimen.

Recent Literature.

Wimmer's Table and Notes on Human Osteology. For the Use of Students of Medicine. By SEBASTIAN J. WIMMER, M.A., M.D. With a preface by PROF. WILLIAM F. WAUGH. Philadelphia: The Medical Publishing Company. 1894.

Our opposition to anything of the nature of an anatomical compend has been so persistent and (in our own opinion) so well founded, that we find it difficult to give the praise to this little work which is no more than its due. None the less it states the main facts of osteology so clearly, simply and correctly that we must say that if used, and not abused by being taken as a substitute for a text-book, it is distinctly a valuable help to the student.

Syllabus of the Obstetrical Lectures in the Medical Department of the University of Pennsylvania. By RICHARD C. NORRIS, A.M., M.D., Demonstrator of Obstetrics, University of Pennsylvania; Assistant Obstetrician, University Maternity; Physician to the Methodist Episcopal Hospital; Obstetrical Registrar, Philadelphia Hospital; Consulting Obstetrician and attending Gynecologist, South Eastern Dispensary and Hospital for Women and Children. Third edition. Philadelphia: W. B. Saunders. 1894.

The primary and chief value of this work is, of course, to the students of the University of Pennsylvania, for whose use it was written. It is secondarily of interest to the specialist as offering an easy method of judging of the obstetrical instruction given in so prominent a school. The book is exactly what its title implies—a syllabus of Dr. Hirst's lectures—and little can be added to its title-page by a review except to say that it seems to be a good syllabus.

IDIOPATHIC HYPERTROPHY OF THE HEART.

It was formerly taught that hypertrophy of the heart is always consecutive to some valvular lesion or some other more or less distant impediment to the free circulation of the blood; the heart enlarges to overcome the obstruction, whether this exists in the valves or in the blood-vessels. It is only thirty years ago that Bour, in a thesis published in Giessen, described eighteen cases of hypertrophy of the heart without any discoverable valvular or arterial alterations.

Since this time, many memoirs have appeared in various parts of the world, especially in Germany, substantiating the existence of an idiopathic hypertrophy of the heart. Many of the cases reported were typical instances of the bovine heart. There is a group of cases of dilatation and hypertrophy consequent on prolonged overexertion, and treated of by the French writers under the head of *le cœur surmené* (the overworked heart). This affection was first noticed by Peacock among the Cornwall miners; was next described by Clifford Albutt, and was afterwards observed and studied by Da Costa and others, in soldiers who had, during the late American war, been disabled by forced marches and other hardships.

Osler writes of patients who frequently come under the observation of the physician: "They are able-bodied men, at the middle period of life, and complain first of palpitation or irregularity of the action of the heart, shortness of breath, and subsequently the usual symptoms of cardiac insufficiency develop. On inquiring into the history of these patients, none of the usual etiological factors causing valve disease are present, but they have always been engaged in laborious occupations, and have usually been in the habit of taking stimulants freely."

Schott, of Naubeim, says that the existence of such a condition following overstrain can no longer be doubted. He has made experiments with the view of producing acute overstrain of the heart in healthy and vigorous men by making them struggle till dyspnoea

came on. In a recent series of experiments the body of the struggling person was compressed by a girdle applied below the arch of the ribs, thus increasing the intracardiac pressure and making the action of the heart extraordinarily difficult. All the symptoms characteristic of acute overstrain of the heart were thus produced, namely, dyspnoea, arrhythmia of the pulse, tachycardia, etc., and above all dilatation of the heart, including auricles and ventricles. In the second series of experiments the heart sometimes assumed quite considerable dimensions. Cases were also mentioned in which symptoms of acute overstrain of the heart were produced by lifting heavy objects, climbing mountains, dancing, and particularly tight-lacing and velocipede-riding.¹ Such cases are reported by Jackson in a paper recently published in the JOURNAL.² And in connection with this subject it is well to be acquainted with the class of cases described by Da Costa, under the head of "Cardiac Asthenia, or Heart Exhaustion."³

At the recent meeting of the International Medical Congress held in Rome (March 29 to April 6, 1894) Laache, of Christiania, Norway, spoke of the subject of idiopathic hypertrophy in connection especially with alcoholism and overexertion. Alcohol is a prominent etiological factor, and in particular, beer-drinking. Here he is in accord with Bollinger who has published some interesting researches on idiopathic hypertrophy of the heart, and assigns to beer-drinking an important etiological part. According to these writers, the plethora provoked by the immoderate ingestion of beer, and the augmentation in the blood-pressure therefrom resulting, joined to a direct noxious action on the heart-muscle explains the hypertrophy and other heart troubles which are becoming increasingly frequent in certain cities of the Empire, "resulting in a mortality scarcely less than that caused by tuberculosis." The condition of the heart thereby caused is spoken of in Bavarian parlance as the *beer-heart*. This *beer-heart* is very prone to fatty degeneration; secondary valve-disease due to consecutive endocarditis is not rare. Strümpell affirms that this condition is very common in the draymen and workers in the breweries of Erlangen, very few of whom pass the forty-fifth year without indications of dilatation and hypertrophy of the heart (Osler). At the post-mortem examination the valves may be quite healthy, the aorta smooth, and no extensive arterio-sclerosis, or renal disease be found. The heart weighs from eighteen to twenty-five ounces.

Laache admits the frequent occurrence of cardiac hypertrophy among the Scandinavian nations from overstrain, especially in conjunction with heredity and habits of alcoholism. The Norwegians are very fond of gymnastic exercises, and these when indulged in immoderately cause overstrain of the heart. A medical confrère of his lost his life by heart-rupture after a long tramp on the Norwegian "ski" or skates. Sudden death is, in fact, according to the writer, a very

¹ Quoted from Sajous' Annual, 1891.

² February 1, 1894, p. 112.

³ American Journal of the Medical Sciences, April, 1894.

frequent termination of idiopathic cardiac hypertrophy with degeneration. So frequent, in fact, is this form of death in Scandinavia, that (in the words of this writer) "one can hardly open a newspaper without meeting with an account of a case of the kind, brought on by heart-failure or heart-paralysis." But, he does not overlook the wonderful recuperative power sometimes displayed by the heart, and which led Haller in his day to apply to it the epithet *ultimum moriens*.

With regard to the word *idiopathic* as applied to the cardiac enlargement resulting from the causes above mentioned, the word is quite correct. An idiopathic disease is a disease which exists by itself, and is not dependent on another (Robin). Some writers have spoken of an idiopathic hypertrophy of the heart as an affection occurring without discoverable cause. There is no sufficient evidence that any such affection has ever existed. The mechanism of idiopathic hypertrophy is not essentially different from that of hypertrophy secondary to valvular disease or renal sclerosis, and may be summed up in these words: *augmentation of blood-pressure*.

THE ELEVENTH INTERNATIONAL MEDICAL CONGRESS.

ALL accounts of the Eleventh International Congress—those directly from Italian sources, those sent to the English, to the German and to our own journals, and those which we get directly from returning delegates—concur in indicating that it was at once the largest and the least well-organized of these international medical gatherings. There was no lack of good-will or of hospitable intention on the part of the hosts; but there unquestionably was an evident lack of previous appreciation of the inherent difficulties, of the great numbers, of the necessary conveniences, as well as a lack of executive capacity.

The truth is, the very success of these meetings threatens to be their ruin. It is next to impossible to provide properly for thousands of men speaking different languages who come together for five or six days, and it is quite impossible to do any sort of justice even to a small part of four thousand papers in three or four different languages.

The picnic side of these gatherings is the one which has developed the most strikingly, and which threatens to overshadow the rest. For those who can afford the time and the expense, the outing is excellent, moreover, they may make interesting professional acquaintances. Those who stay at home may console themselves with the reflection that they get the scientific results—a little later, perhaps, but always more fully and more satisfactorily—without the fuss and the scramble which are getting to be inevitable accompaniments of the Congress. It seems a fair question whether the unrestrained acceptance of many thousand papers is to be approved. It offers a golden opportunity, to be sure, for many to obtain the happiness of capitalized print; but a judicious selection would add much to the merit of the meetings.

MEDICAL NOTES.

CHARCOT'S SUCCESSOR.—Dr. Raymond of the Salpêtrière has been chosen by the Faculté de Médecine as Charcot's successor by a vote of thirty in thirty-one.

YELLOW FEVER AT RIO JANEIRO.—The yellow fever still continues to increase at Rio Janeiro, the deaths now numbering nearly a hundred every day, while there are between four and five hundred new cases every week.

A CASE OF SMALL-POX AT SUSSEX, N. B.—A case of small-pox has occurred in Sussex, N. B., the patient being a physician just returned from New York where he had attended a case of small-pox the week before in connection with his hospital work.

SAMUEL WARREN, D.C.L.—For the benefit of those of our readers who were misled by a statement in our editorial of last week on "The Doctor in Fiction," we call attention to the fact that Samuel Warren was not a physician, though he might have been. He studied medicine at Edinburgh, but lapsed into the law, which profession he followed with some distinction.

THE REAPPEARANCE OF CHOLERA.—The cholera has made its appearance again for the summer of this year. Throughout the winter there have been smouldering centres of the disease in Russia and in some Turkish districts, though not acknowledged by the governments of those countries. Since the first of April so many cases have occurred in Czenstochow, in Poland, that the town has been quarantined. The disease is now admitted to be epidemic in Kovno, Kaliss, Plock and Warsaw. In Constantinople, there are officially no cases, but the disease has been spreading rapidly throughout the city, no longer being confined to the poorer classes. Several of the foreign legations have left the city for more healthy quarters. On April 23d, 65 cases of "cholera" were reported to the health authorities of Lisbon, and on the following day 104. The disease is reported to be present in many villages in the interior.

THE D. HAYES AGNEW MEMORIAL.—The D. Hayes Agnew Memorial Committee, organized a year ago to secure a lasting memorial of Dr. Agnew in connection with the University Hospital, Philadelphia, report that subscriptions have been promised of sufficient amount to give reasonable assurance of the successful carrying out of this plan which includes not only a children's ward, but also an amphitheatre and ward class-rooms, with wards for men and for women,—the whole to be a model in perfection of details and completeness of appliances, and thus a fitting representation of the work of Dr. Agnew. The State Legislature, at its last session, made an appropriation of \$80,000 to the University Hospital for building purposes, provided that an equal sum of \$80,000 be raised by the friends of the Hospital. Of this sum about \$60,000 has already been raised, leaving only about \$20,000 more to be secured by May 1, 1894.

It is hoped to secure, in addition to this sum, a nucleus for an endowment fund for the new wing, which is to be given the name of D. Hayes Agnew.

SMALL-POX IN CHICAGO. — The small-pox epidemic in Chicago is at present assuming most threatening proportions. Throughout the early winter scattered cases were reported and cared for in the hospital, but during the last two months the cases have increased so rapidly that the health department has been entirely unable to control the spread of the disease. During March there were 308 cases, and at present there are 200 patients in the small-pox hospital, which is so crowded that many of the sick are sleeping on mattresses on the floor. Ten small-pox patients have been taken into the County Hospital, which is now quarantined with its 300 other patients, who cannot be discharged. Sixty patients are already quarantined in forty-eight private houses throughout the city for want of any kind of hospital to send them to. The house-to-house canvass shows a wide dissemination throughout the city, and the increase of cases during the last week was 126. The most seriously affected portion of the city is the southwestern section. In many cases the disease has not been reported until after death, the inspectors finding three bodies in one house last week.

ECHOES OF THE CONGRESS AT ROME.

AMONG other interesting facts gleaned from an Italian source we learn that there were consumed at the luncheon given at the Baths of Caracalla, six thousand bottles of wine, of which three thousand were champagne; eighty lambs; five hundred fillets of beef; one thousand chickens; twenty-two thousand sweet-cakes; twelve barrels (*caratelli*) of beer; and forty thousand rolls (*paynotelle*). This was accomplished by about ten thousand participants. The Italian accounts of the scene around the buffet at the reception given in the great Capitoline Hall read more like an epic rendering of an Irish wake than the story of a public official reception of the world's representatives of medical science in one of the oldest European capitals. But the reminiscences of that famous Berlin banquet at the last Congress should have prepared us for the possibility of these things. "Congressists" who have discussed and listened to many papers require much food and drink; and after all what is a *pasta dolce* and a *bicchierino di marsala* among one — especially after he has fought for it!

A CORRESPONDENT writes us of the absolute failure of the attempt made to organize a bureau of information for the members from the United States and Canada, where those who knew no Italian (the large majority) might be directed in their need. As none of the Italians even seemed able to give any information or to know anything about it at all, the attempt naturally came to an undeserved and lamentable end. As the *Medical Record* says, "A more go-as-you-please and never-get-there Congress was probably never held."

MR. RUSKIN has called opera as sung in Italy "the

vomiting up of hopelessly damned souls out of still carnal throats," but a theatre full of Congressists paid six dollars a seat to hear Verdi's "Traviata" poorly sung.

THE site of the Policlinico was not chosen for convenient reaching by the members of the Congress. It was well enough in Rome to take a cab out, but they did not wait during the meetings. One could readily ride out, *sed retrogrere gradum hic labor est*, along a newly-built and dusty Roman road — when there is no luncheon in one's stomach and no idea of what has really been said is within one's mind.

IT was a serious grievance to many of the wives of the members that they were not received by the Queen. They could not appreciate the etiquette which excluded them as not having been previously presented at Court.

AN INTERNATIONAL HONOR TO DR. MURPHY. — The International Medical Congress, in appointing its honorary presidents for the year, made Dr. J. B. Murphy, of Chicago, president for the United States.

A PROPOSED INTERNATIONAL PEDIATRIC ASSOCIATION. — During the International Medical Congress at Rome a meeting was held at the house of Dr. Blasi, President of the Section of Pediatrics, to arrange the preliminaries for the organization of an International Pediatric Association, one of the chief objects of which will be to improve the present methods and facilities for giving instruction in diseases of childhood.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — During the eight days ending at noon, April 25, 1894, there were reported to the Board of Health of Boston the following numbers of cases of acute infectious disease: diphtheria 36, scarlet fever 60, measles 22, typhoid fever 16, small-pox 3 (and 1 death). There are now seven cases of small-pox in the hospital. For the six days ending April 25th, 24 cases of small-pox were reported to the State Board of Health, 23 from Chicago and 1 from Holyoke.

A WARNING TO PHYSICIANS IN BOSTON. — Physicians in Boston and vicinity are warned against a swindler who calls in the doctor's absence with a pretended order to repair the rubber stamps.

AN OUTBREAK OF DIPHTHERIA IN WILLIAMSTOWN. — The Board of Health has closed the Centre school of Williamstown on account of the prevalence of diphtheria. This school includes high, grammar and primary grades.

ONE HUNDRED AND ONE YEARS OLD. — Mrs. Betsey Davis, of Mansfield, Mass., celebrated her one hundred and first birthday on April 18th. She was the daughter of an early French settler named Dansance, and the house in which she was born is still standing in Whiteville, a part of East Foxboro.

THE FIRST CONVICTION UNDER THE CONNECTICUT MEDICAL PRACTICE ACT. — The first case brought to trial under the new Medical Practice Act of Connecticut occurred last week at Waterbury, in

that State, when a "Dr." Helen Ashley Keene was fined one hundred dollars and costs for practising without a license. She has appealed to the District Court under bonds.

THE NEW ENGLAND CREMATION SOCIETY.—A meeting of the New England Cremation Society, which was made open to the public, was held in Boston on April 17th. The report of the Society shows a membership of nearly two hundred, among whom are sixteen physicians and five clergymen.

TYPHOID FEVER AT WINDSOR, VT.—A most serious epidemic of typhoid fever exists at Windsor, Vt., there being at present 180 cases. There have been eight deaths already. The serious nature of the situation can be appreciated when it is realized that the ratio of sick to the total population is about one to five or six. The investigation of the outbreak has given a most convincing, and it is to be hoped useful, lesson upon the danger of contaminated water-supply. In January last, a case of typhoid of doubtful origin occurred in a farm-house about 200 feet from the spring and brook which supply the town reservoir. The house stood about 80 feet above the level of the brook, and there was a natural surface drain from the house and out-buildings to the valley below. There is no evidence of any especial precautions having been taken during the illness of the patient to prevent the discharges being mingled with the usual drainage. During the spring thaws all these infected excreta found their way into the brook and the town reservoir. In March, several cases broke out in the village; and within a few days the disease was general and widespread. Since the undoubted pollution of the regular water-supply has been proved, the local Board of Health has issued a warning against the use of water from the town reservoir, and has supplied water from springs in other localities to families who have no wells of their own. Several cases of typhoid fever have occurred in neighboring towns, it is said, among those who derive their water in part from Windsor. Business and all social life are at a complete standstill, and the labor devolving upon the physicians and those not yet ill, has become most taxing. It is to be hoped that so plain a lesson will be remembered, and that in each of the hundred houses now visited care is taken that all the wells and other springs in the town are not further infected.

NEW YORK.

VACCINATING UNDER POLICE PROTECTION.—On the night of April 18th a corps of fifty vaccinators from the Health Department, escorted by one hundred policemen, made a descent upon what is known as Red Hook, a thickly populated tenement-house district of Brooklyn, and vaccinated five thousand people. The territory covered includes eight blocks, and two weeks ago the health officers attempted to carry out a similar crusade; but, as they were then unaccompanied by the police, the inhabitants resisted and drove them off the field with clubs and broomsticks.

WILLIAM A. CONWAY, M.D.—Dr. William A. Conway, Coroner's Physician, died at his residence, 270 East Broadway, on April 17th, after a month's illness. He was born in New York City in 1840. He received his collegiate education at St. Francis Xavier College, and in 1866 was graduated from the College of Physicians and Surgeons, New York. He was connected with the coroner's office for nine years, and had just entered his fourth term of office as deputy coroner. Dr. Conway had always practised in his native city, and was especially identified with the east side of New York, where he had grown up and where he was held in high esteem by a large circle of friends.

PHILADELPHIA.

PHILADELPHIA COUNTY MEDICAL SOCIETY AND THE CODE.—At a meeting of the Philadelphia County Medical Society, held April 18th, the following resolutions were adopted:

Whereas, The Code of Ethics of the American Medical Association declares it derogatory to professional character for a physician to dispense or in any way promote the use of a secret nostrum; and the American Medical Association, by a resolution unanimously adopted at its meeting in 1892, forbade the advertising of such nostrums in its journal; and

Whereas, The Journal of the Association has continued to advertise such nostrums, and, in defence of its course in this particular, has published an anonymous personal attack on a member of the American Association and of this Society;

Resolved, That the Philadelphia County Medical Society respectfully demands that the Trustees of the Journal shall in their public official acts respect the spirit and letter of its Code of Ethics, and that the columns of its Journal shall not be used for the anonymous personal abuse of members in good standing.

Resolved, That a copy of these resolutions be transmitted to the Medical Society of the State of Pennsylvania, and to the American Medical Association and to the weekly medical journals.

Miscellany.

DR. WILLIAM PEPPER'S RESIGNATION AS PROVOST OF THE UNIVERSITY OF PENNSYLVANIA.

DR. WILLIAM PEPPER has presented his resignation of the office of Provost in the following communication to the Trustees of the University of Pennsylvania:

With deep thankfulness I recognize that the University has reached a stage of development and prosperity which justifies me in laying down the high office you intrusted to me more than thirteen years ago, and which I have held as long as it was possible to combine the administrative labors of Provost with the demands of medical teaching and practice. This time has now passed, and I beg therefore to tender my resignation to take effect after the coming Commencement.

The close of the current session will witness the completion of the formative period of the University. From a group of disconnected schools there has been gradually organized a great academic body, complete in its unity and instinct with varied yet harmonious activities. Mutual

confidence and co-operation have developed a system strong enough for effective central control, yet so flexible as to admit affiliation with many separate organizations.

To our University is due the credit of establishing university extension in America, yet the important and successful society which controls this movement has no organic relations with the University, save that the Provost is *ex officio* the Honorary President. The Wistar Institute of Anatomy and Biology, a magnificent memorial of the founder of American Anatomy, has a separate charter and is not owned by the University, yet is governed by a Board the majority of whose members are appointed by yourselves. The University Hospital, which has grown so prosperously, is a special trust administered by a Board of twenty-two members, only four of whom are appointed by the Trustees of the University.

The Department of Archæology and Paleontology, under whose energetic operations there is developing rapidly a Museum of high rank, is governed by a Board of not less than thirty-six members, of whom only six are appointed by the Trustees of the University. Reference is made to these familiar instances to illustrate the admirable results which may develop under a system which excludes rigid control, and rests upon mutual confidence and a common devotion to a great cause.

It has been a chief aim of your Board to demonstrate to the people of this great Commonwealth that the University is truly the voluntary association of all persons and of all agencies who wish to unite in work for the elevation of society by the pursuit and diffusion of knowledge and truth. No less important has been the establishment of the principle that the University, so far from being a private and exclusive corporation, is essentially and organically a part of the municipality. The large future of the University was secured when, in 1872 and in 1883, City Councils voted, without a dissenting voice, the transfer to the University of splendid tracts of ground in consideration of the establishment in perpetuity of fifty free beds in the Hospital for the poor of Philadelphia, and of fifty prize scholarships in the College, to be awarded to graduates of the public schools of Philadelphia. The subsequent accessions of territory which have brought the domain of the University up to fifty-two acres, in a compact body in the centre of the city, have been the logical consequences of these great steps; and so faithfully have all the trusts and conditions been executed, that it has come to be recognized by the municipal authorities that it is more profitable to the city to give freely to the University anything in its power to bestow which is needed for the development of that institution than to dispose of it elsewhere even at a great price. It needs only the resolute continuance of this wise policy to secure for the University full recognition as a branch of the City Government with a duly accredited representative of its great constituency in her Councils.

Progress has also been made toward the establishment of the essential principle that the University is in right, and should be in fact, the head of the educational system of the entire Commonwealth. We may fairly claim to have done much toward securing a recognition of the view that the encouragement of higher education, by the municipality and the legislature, is as proper and important in the older communities of America as it has been decided to be in the newer States.

While the unification of the University and the establishment of broad lines of policy may seem to be the most important work of the past thirteen years, it will be found that the resources of the University and the educational work in each department have been successfully promoted. In 1881 its property was fifteen acres, while at present there are owned or controlled by the University, in a continuous tract and solely for educational purposes, not less than fifty-two acres. The value of the lands, buildings and endowment in 1881 may be estimated at \$1,600,000; it is now over \$5,000,000. Prior to the date of the late John Henry Towne's great bequest, the University had never received a single large gift or legacy. During the current year ending September 1, 1884, there will be ac-

quired in lands, buildings, money and subscriptions not less than \$1,000,000. The members of the teaching force in 1881 numbered 88, and the students in all departments 981; at this time the former are 268, and the attendance has reached 2,180, representing every State of the Union and no less than thirty-eight foreign countries. The College Department has attained a national distinction, and its complete reorganization, which has now been accomplished successfully, gives sure promise of sound and rapid progress. The Medical School has been advanced to pre-eminence in equipment and prosperity, while plans now maturing will place it abreast of the great schools of Europe. The Law School has effected the prolongation and elevation of its curriculum, and has deservedly won national repute. Encouraging progress has been made toward providing an admirable building on an approved site, so that the future eminence of the school is assured. Gratifying reports may be made of the position of the Dental and Veterinary Departments; and well-considered plans for their still further development need only time for their fulfilment. Upon this vigorous basis rests the Department of Philosophy, which, although organized as late as 1884, and still without special endowment, has already one hundred and fifty-four students. It represents the University in its highest and best intellectual life; it affords inspiration to teachers and students; it has enabled us to extend the richest privileges of the University to women on equal terms with men; it points the way to large endowment of rich research and advanced scholarship.

The necessity of dormitories to the development of the best university life has come to be clearly recognized by your Board, and generous friends stand ready to supply this important need.

It is pleasant, in these days of strength and prosperity, to reflect upon those of doubt and struggle, when ridicule met the assertion, the truth of which is now freely conceded, that nowhere can a great university be developed so favorably as in a great city.

In closing my term of service as provost, I may be permitted to allude to the motives which impel me to this step. The labor of these thirteen years has been so severe, in connection with my professional duties in the Medical School, and with the extensive medical practice necessary to provide the funds which have enabled me to initiate nearly all of the large movements undertaken during this time, that I have often felt that my life was specially preserved for the work. It has, however, been growing evident, for several years past, that the time was approaching when the immense extent of the University interests would demand the undivided activity of the most energetic man. It has now become necessary for me to choose between administrative work and medical science. My devotion to the latter has determined the choice.

No official has ever been associated with more affectionate and indulgent colleagues, or has enjoyed more loyal co-operation than has been extended to me. I am confident that the choice of my successor will be wisely and promptly made. I do not leave the service of the University, but will remain, with more free hands, ready to serve her every interest with utmost devotion.

I invoke upon your continued labors in the government of this grand institution the richest blessings of Almighty God, who has in the past so signally guarded it.

THE SEWAGE SYSTEM IN FITCHBURG.

THE sanitary relations of one community to another are in no wise different from those of individual persons. A man is safe from filth disease if he himself, his house, and his surroundings are clean; but, it is little security for him to know that his own house is properly plumbed, if his sewage enters a sewer without any outlet, or his next-door neighbor enters all his

waste sewage into a sluggish-flowing brook which runs by his premises. With cities it is the same. The increasing intercommunication of our cities and towns — in the way of business, especially in supplying food or milk, the one to the other — makes the sanitary arrangements which shall prevent an outbreak of typhoid or other communicable disease in any town a matter of no small interest to a wide circle of settlements. A recent address of Dr. C. W. Spring, the city physician of Fitchburg, Mass., calls attention to a state of matters which might well be seriously considered. He says:

"The system of sewage disposal in Fitchburg, if such a process can be called a system, is to discharge the sewage, and almost everything else that is not needed, into the Nashua River. The river entering the town at its south-westerly corner, is a small stream, which is soon increased in size by the junction of two brooks. From a point above these tributaries, at the extreme upper end of the city, to South Fitchburg, a distance of about 6.8 miles, the river has a fall of about 275 feet. The valley through which the river flows is quite narrow, and along its banks is located the greater part of the population of the city. Within this distance the river receives the sewage of some 20 miles of sewers from 21 separate openings, and the refuse, in whole or in part, of 13 paper mills, 3 worsted mills, 8 yarn mills, 1 cotton-batting mill, 5 gingham mills, a gas works, various machine shops, and many other establishments of various kinds — to say nothing of the large amount of rubbish which is thrown directly into its waters. Below the city the valley widens, and the river is joined by Baker's Brook, which though it drains an area about one-fourth as large as that drained by the main stream, is almost free from sewage pollution."

The pollution of the river is well shown by the summary of analyses made at different points along its course. Shortly after reaching the city the river water begins to assume its characteristic milky appearance. The total solid matter, both dissolved and suspended, is 8 parts in 100,000, and the number of bacteria for each cubic centimetre is 496. Shortly after being joined by the first brook the water contains 16 parts of solids and 7,600 bacteria. For a short distance there is slight improvement, but the pollution rapidly increases, lower in the city, to 17 parts of solids and 45,600 bacteria, to 21 parts of solids with 56,400 bacteria, until half a mile below the last paper mill the maximum pollution is reached — the water being thick, muddy and offensive to the smell, the solids reaching 23 parts and the number of bacteria 111,600. The increase in pollution in the fifteen years from 1876 to 1891 was nearly 300 per cent.; the figures showing in 1876 an increase between the most northern and southern points in the river from 2.64 to 7.46, and in 1891 from 7.50 to 20.50.

"The Nashua River is not, however, the only stream in the city which is made a public sewer. Punch Brook has long been, and now is, a public nuisance. It receives a large amount of sewage, either directly or indirectly, and running as it does often concealed from view, and underneath houses, its danger is all the greater. If it was open its whole distance its waters might become a little less foul from the natural oxidation which would take place by contact with fresh air. It is hardly necessary to say that such a nuisance should be abated."

A BILL TO PROVIDE FOR THE REGISTRATION OF PHYSICIANS AND SURGEONS IN THE STATE OF MASSACHUSETTS.

THE following bill has been passed by the Massachusetts Senate:

SECTION 1. The governor, with the advice and consent of the council, shall appoint seven persons, resident in this Commonwealth, who shall be graduates of a legally chartered medical college or university having the power to confer degrees in medicine, and who shall have been actively employed in the practice of their profession for a period of ten years, who shall constitute a board of registration in medicine. Such persons shall be appointed and hold office for terms of one, two, three, four, five, six and seven years, respectively, beginning with the first day of July in the present year, and until their respective successors are appointed, and thereafter the governor, with the advice and consent of the council, shall appoint before the first day of July in each year one person qualified as aforesaid to hold office for seven years from the first day of July next ensuing. No member of said board shall belong to the faculty of any medical college or university. Vacancies in said board shall be filled in accordance with the provisions of this act for the establishment of the original board, and the person appointed to fill a vacancy shall hold office during the unexpired term of the member whose place he fills. Any member of said board may be removed from office for cause by the governor with the advice and consent of the executive council, and not more than three members of said board shall at one time be members of any one chartered State medical society.

SECT. 2. The members of said board shall meet on the second Tuesday of July next, at such time and place as they may determine, and shall immediately proceed to organize by electing a chairman and secretary, who shall hold their respective offices for the term of one year. The secretary shall give to the treasurer and receiver-general of the Commonwealth a bond in the penal sum of five thousand dollars, with sufficient sureties to be approved by the governor and council for the faithful discharge of the duties of his office. The said board shall hold three regular meetings in each year, one on the second Tuesday of March, one on the second Tuesday of July and one on the second Tuesday of November, and such additional meetings at such times and places as it may determine.

SECT. 3. It shall be the duty of said board immediately upon its organization to notify all persons practising medicine in this Commonwealth of the provisions of this act by publication in one or more newspapers in each county, and every such person who is a graduate of a legally chartered medical college or university having power to confer degrees in medicine, and every person who has been a practitioner of medicine in this Commonwealth continuously for a period of three years next prior to the passage hereof, shall upon the payment of a fee of one dollar be entitled to registration, and said board shall issue to him a certificate thereof signed by the chairman and secretary.

SECT. 4. Any person not entitled to registration as aforesaid shall, upon payment of a fee of ten dollars, be entitled to examination, and if found qualified by four or more members of said board shall be registered as a qualified physician and shall receive a certificate thereof as provided in section three. Any person refused registration may be re-examined at any regular meeting of said board within two years of the time of such refusal, without additional fee, and thereafter he may be examined as often as he may desire upon the payment of the fee of ten dollars for each examination. Said board, for criminal cause shown and after hearing, may by unanimous vote revoke any certificate issued by them and cancel the registration of the person to whom the same was issued. All fees received by the board under this act shall be paid by the secretary thereof into the treasury of the Commonwealth once in each month.

SECT. 5. The compensation, incidental and travelling expenses of the board shall be paid from the treasury of the Commonwealth. The compensation of the board shall be ten dollars each for every day actually spent in the discharge of their duties, and three cents per mile each way for necessary travelling expenses in attending the meetings of the board, but in no case shall any more be paid than was actually expended. Such compensation and the incidental and travelling expenses shall be approved by the board and sent to the auditor of the Commonwealth, who shall certify to the governor and council the amounts due as in case of all other bills and accounts approved by him under the provisions of law: *provided*, that the amounts so paid shall not exceed the amount received by the treasurer and receiver-general of the Commonwealth from the board in fees as herein specified, and so much of said receipts as may be necessary is hereby appropriated for the compensation and expenses of the board as aforesaid.

SECT. 6. The board shall keep a record of the names of all persons registered hereunder, and a record of all moneys received and disbursed by said board, and said records or duplicates thereof shall always be open to inspection in the office of the secretary of the Commonwealth. Said board shall annually

report to the governor, on or before the first day of January in each year, the condition of medicine and surgery in this Commonwealth, which report shall contain a full and complete record of all its official acts during the year, and shall also contain a statement of the receipts and disbursements of the board.

SECT. 7. It shall be the duty of the board to investigate all complaints of disregard, non-compliance or violation of the provisions of this act, and to bring all such cases to the notice of the proper prosecuting officers.

SECT. 8. On and after the first day of January, in the year eighteen hundred and ninety-five, the board shall examine all applicants for registration as licensed physicians or surgeons in this Commonwealth. Applicants must give satisfactory proof of being twenty-one years of age and of good moral character; and every applicant who is a graduate of and has received a degree of M.D. from a legally chartered medical college or university having power to confer degrees in medicine in this Commonwealth, shall be entitled *prima facie* to be registered under this act upon payment of the fees herein provided.

SECT. 9. Examinations shall be, in whole or in part, in writing, and shall be of an elementary and practical character. They shall embrace the general subjects of surgery, physiology, pathology, obstetrics and practice of medicine, and shall be sufficiently strict to test the qualifications of the candidate as a practitioner of medicine.

SECT. 10. Whoever not being registered as aforesaid, shall advertise or hold himself out to the public as a physician or surgeon in this Commonwealth, by appending to his name the letters "M.D.," or using the title of doctor, meaning thereby a doctor of medicine, shall be punished by a fine of not less than one hundred nor more than five hundred dollars for each offence, or by imprisonment in jail for three months, or both.

SECT. 11. This act shall not apply to commissioned officers of the United States Army, Navy or Marine-Hospital Service, or to a physician or surgeon who is called from another State to treat a particular case, and who does not otherwise practise in this State, or to prohibit gratuitous services; nor to clairvoyants, or to persons practising hypnotism, magnetic healing, mind cure, massage methods, Christian science, cosmopathic or any other method of healing; *provided*, such persons do not violate any of the provisions of Section ten of this act.

SECT. 12. For the purposes of the appointment of said board, and of registration of persons by it hereunder, this act shall take effect upon its passage, and shall take full effect on the first day of January in the year eighteen hundred and ninety-five.

PROFESSOR TYNDALL.

PROFESSOR HUXLEY¹ draws the following clear picture of Tyndall's character, at the time when he first became acquainted with him:

"My elder by some five years, Tyndall's very marked and vigorous personality must have long taken its final set when we foregathered in 1851. But I found my new friend a difficult subject — *incerta sedis*, as the naturalists say; in other words, hard to get into any of my pigeon-holes. Before one knew him well, it seemed possible to give an exhaustive definition of him in a string of epigrammatic antitheses, such as those in which the older historians delight to sum up the character of a king or leading statesman. Impulsive vehemence was associated with a singular power of self-control and a deep-seated reserve, not easily penetrated. Free-handed generosity lay side by side with much tenacity of insistence on any right, small or great; intense self-respect and a somewhat stern independence, with a sympathetic geniality of manner, especially toward children, with whom Tyndall was always a great favorite. Flights of imaginative rhetoric, which amused (and sometimes amazed) more phlegmatic people, proceeded from a singularly clear and hard-headed reasoner, overscrupulous, if that may be, about keeping within the strictest limits of logical demonstration; and sincere to the core. A bright and even playful companion, Tyndall had little of that quick appreciation of the humorous side of things in general, and of one's self in particular, which is as oil to the waves of life, and is a chief component of the

worthier kind of tact; indeed, the best reward of the utterer of a small witticism, or play upon words, in his presence, was the blank, if benevolent, perplexity with which he received it. And I suppose that the character-sketch would be incomplete, without an explanation of its peculiarities by a reference to the mixture of two sets of hereditary tendencies, the one eminently Hibernian, the other derived from the stock of the English Bible translator and Reformer."

MEASLES AND THEOLOGY.

ABOUT two years ago a curious incident was reported from a Swiss village, regarding an epidemic of measles which attacked the children only of Catholic parents. A repetition of this doctrinal distribution of disease is now reported by Dr. Gryglewicz, of Jutroschin.¹

Under the date of January 11th, he writes that for three weeks there had been a sharp epidemic of measles, and in all that time he had found the disease only among Catholic children. Some grades of the Catholic schools were closed as over eighty per cent. of the pupils were ill. Upon inquiry among the evangelical schools, it was found that not a child was absent. In his practice, he had seen no Protestant children ill. The 2,000 inhabitants of Jutroschin are about evenly divided between Catholics and Protestants; and there are about 150 Jews in the town, among whom there was one case of measles. No explanation of this curious occurrence has yet been found. If in the future the present difficulties of bacteriological etiology and diagnosis are to be further involved by theological and denominational difficulties, the path of the advancing scientific physician will be no easy road to fact or fame.

THE HINDU SYSTEM OF MEDICINE AND THE SECRET OF SUCCESS IN PRACTICE.

THE eighth fascicle of the *Charaka-Samhita* contains a most interesting account of the basis of the Hindu system of medicine as it includes a classification of all illnesses. "Diseases that occur are of four kinds: first, accidental, as wounds inflicted by nails, or falls, incantations, curses, assaults of evil spirits, acts of violence, binding, cords, burns and lightning. All other diseases are constitutional, and have three classes due to disorders of wind, bile and phlegm. Accidental diseases arise at first with pain, and afterwards cause disorders of wind, bile and phlegm. In constitutional diseases, wind, bile and phlegm in the first instance become disordered and afterwards lead to pain.

"The respective divisions of the body that constitute the seats of the three faults are as follows: The hypogastric or pubic region, the place where the feces collect, the regions about the loins, the thighs, the feet, and the bones, are the seats of wind. That portion of the stomach, however, where digestion goes on, among the seats of wind, is in particular the seat thereof. Sweat, the thorax saliva, blood, and that portion of the stomach where undigested food remains, are the seats of bile. Amongst these all, the last is especially the seat of bile. The thorax, the head, the throat, and all the joints, that portion of the stomach

¹ Popular Science Monthly, March, 1894.

¹ Deutsche Med. Zeitung, 1894, No. 29.

which holds the undigested food, and the fat, are the seats of phlegm. Amongst these all, the thorax is especially the seat of phlegm. Verily, wind, bile and phlegm wander over every part of the body. In their normal or unexcited state they produce beneficial results, such as growth, strength, good complexion and clearness of senses. When not in their normal state, they produce many evil consequences called disease."

There then follows a most extended nosology of the diseases due to those three causes, from which it is readily perceived that wind, bile and phlegm are used as technical terms implying certain states of the physical constitution and not at all in the ordinary sense of atmosphere, hepatic secretion or mucous exudations. Having carefully enumerated each with its appropriate treatment, the eighty diseases of wind, the forty of bile, and the twenty most common of the innumerable diseases due to phlegm, the writer closes with the following injunction to the reader:

"The diseases should first be carefully ascertained. After this, the medicine to be applied should be carefully selected. Subsequent to this the physician should, with full knowledge of consequences, commence the treatment. That physician who, without carefully ascertaining the disease, commences the treatment, seldom meets with success even if he be well conversant with medicines and their application. That physician who is well conversant with the features of disease, who has a thorough acquaintance with all medicine, and who has knowledge of the considerations dependant upon time and place, achieves success without doubt."

LETTERS FROM ROME.

THE ELEVENTH INTERNATIONAL MEDICAL CONGRESS.

ROME, April 10, 1894.

MR. EDITOR.—A few words relative to the Eleventh International Medical Congress just closed in Rome may be of some slight interest to your readers. In some respects the Congress was as much of a success as can be expected of such large and democratic medical assemblies. About 7,000 physicians were registered from all over the world and about 1,500 guests, a larger number than was at Berlin at the last meeting. American physicians were more conspicuous by their absence than by their presence, not quite 200 being on the list, while at Berlin there were over 600. Those who sailed from New York on March 17th, with the expectation of landing in Genoa on the 28th, among whom was Dr. Jacobi, the chairman of the American delegation, were doomed to disappointment. Although the *Kaiser Wilhelm* left her dock promptly at seven o'clock in the morning, she as promptly ran on to the bar in the harbor, and lay there seven or eight hours, thus causing us to lose a day. Over thirty of her passengers were physicians, and they did not reach Rome until Friday, too late for the opening exercises, which took place on Thursday in the presence of the King and Queen of Italy, and a large assemblage completely filling the Costanzi Theatre. Signor Crispi made the address of welcome on the part of the king, Dr. Baccelli followed in a Latin discourse, and Prince Ruspoli greeted the members "in the name of the city of Rome." Virchow gave an admirable paper on the growth of medical science, laying especial emphasis upon "Morgagni and his influence upon anatomical thought."

During the Congress notable addresses were made by

Nothnagel of Austria, on "Modifications of the Organism in consequence of Pathological Alterations"; Bouchard, "On Fevers"; Professor Babes, of Bucharest, "The State in its Relation to the Results of Modern Bacteriological Researches"; Stovis, on "Chemistry and Materia Medica"; Kocher, on "Projectiles and their Effect upon the Wounded." Dr. Murphy, of Chicago, created a very favorable impression with his paper on "Cholecystenterostomy, Twenty Successful Cases"; he also reported 145 laparotomies for appendicitis. Dr. Link, of Terre Haute, Ind., presented a paper in which he claims to have proved by experiments on dogs, as well as by clinical experience, that at least three inches of the tibia and fibula with the periosteum may be removed, as in a compound and comminuted fracture, and new bone be formed *without shortening*! The dressing consists of old linen and thin wooden splints, which are not removed till the patient is well. He lays great stress upon frequent and long-continued douching with water as hot as can be borne. Dr. Turk, of Chicago, read a paper upon the value of swabbing out the stomach with a sponge. He demonstrated his method upon a man said to have a dilated stomach. The apparatus consists of a wire about three feet long with a sponge looking not unlike a sponge tent, about two and a half inches in length by three-fourths of an inch in diameter, fastened to one end. The wire protected by rubber tubing is attached to a rotary machine resembling an egg-beater, or a hand-drill. On introducing the wire into the stomach and turning the handle the sponge is made to revolve rapidly, and can be felt externally in a thin person. Dr. Turk claims that he can thoroughly cleanse not only the stomach in this manner, but that he also pushes the sponge into the duodenum. The patient bore the manipulation very well indeed, often turning the crank himself! There was no vomiting attending the demonstration. We were given to understand that this method is in daily use in the doctor's practice.

The scientific work of the Congress was done in sections, there being seventeen or more of them. As over 4,000 papers were presented, it may be easily imagined that the work of some of the sections was hurried and hence unsatisfactory. An idea may be formed of the work crowded into some of the sections from the fact, that in the official list 50 papers would be put down for one day in physiology, 25 in anatomy, 36 in pathology and pathological anatomy, 43 in obstetrics and gynecology, 93 in surgery, and 124 in internal medicine. The papers were not repeated from day to day in the list. I am told that some rather startling jumps were made in some of the lists, in one instance going from No. 4 to No. 92. The sections began work at eight o'clock in the morning and the general sessions, held a mile away, at four in the afternoon.

The exhibit of surgical instruments and appliances was not as extensive as at Berlin. One noticeable article in the collection was an operating-table made by Stille, of Stockholm, which was adjustable to many positions, and, while being strong and firm, was yet simple and free from complicated contrivances, so liable to get out of order or to refuse to work at critical moments. The electrical exhibit was quite good, a hand-light for the throat being very noticeable.

The social part of the Congress was by no means slighted. Perhaps the most satisfactory feature was the garden-party given at the palace by their Majesties, the King and Queen. At least, it was satisfactory to those who were fortunate enough to receive invitations. The ladies were handsome, the dresses were beautiful, the music by two bands was fine, the weather was perfect, their Majesties were gracious; and upon this occasion, which was almost the only one of which that can be said, the crowd was not too large. The reception given at the Capitol by the city was a great success as regards numbers, elegant toilets, etc. The climax, however, was reached on the last day of the Congress, when a lunch was served at the Baths of Caracalla. Tables were set for about a thousand, while several thousand were present. The struggle to get something to drink—or eat—which took

place about those two tables may be imagined. The position of the two waiters, who were pelted with hard rolls of bread and an occasional plate, was not an enviable one. The crowd was jolly, good-natured and noisy. It almost seemed to be a fit occasion for a repetition of the miracle of the loaves and fishes.

The festivities wound up with a "Battle of Roses" upon the "Corso" in the afternoon, and a torch-light procession in the evening. To those not familiar with the famous carnivals of Rome, it may be said that the "Battle of the Roses" consists of crowds of people in carriages and on foot, promenading up and down this, one of the principal streets, and throwing flowers to whomsoever they choose. When friends meet the scenes are often animated and exciting. The windows are crowded, as well as the streets; everybody is happy, and to a stranger the scene is a novel and interesting one.

The Italians seem highly pleased at the success of the Congress, and certainly great efforts were made by them to make it a success. There were rumors that the next meeting would be held at St. Petersburg.

Very truly yours,

GEORGE W. GAY, M.D.

A FEW NOTES ON ROME AND THE LATE INTERNATIONAL MEDICAL CONGRESS.

ROME, April 6, 1894.

MR. EDITOR:—A little more than two years ago, (Oct. 8, 1891), it was my privilege to have a short communication published in the columns of the veteran *Boston Medical and Surgical Journal*, on "Rome, Her Sanitation and Her Facilities for Holding a Polyglot Medical Congress," in which I ventured to predict, from what I could then learn from a tour through the Eternal City and her suburbs, that though the medical brethren might mobilize from every point of the compass, over all those roads which lead to Rome, yet the old city could abundantly and comfortably provide for all; that the city was well drained, healthy and delightful at every season of the year, though she was at her best in the early spring.

Well! the weary pilgrims came; they have held their Congress, and again scattered, over land and water, to their own countries. All were well-fed and housed, at moderate rates. All were received with a royal welcome, in which the King himself and his beautiful Queen actively participated; luncheon parties and banquets were held on a munificent scale; transportation of every kind was accessible and moderate; and more than five thousand visiting medical practitioners and their friends have left for home without any serious cases of illness developing which could be ascribed to local causes.

Never before did the medical profession, to a greater extent or in a more substantial manner, demonstrate to the world its cosmopolitan character and its integral common brotherhood.

Here, they massed, many of the most eminent and distinguished members of their profession, to offer from a common altar, the fruit of their life-long studies, observations and investigations, not for the benefit of any sect, nation or race, but for the alleviation of the sufferings, and for the well-being of all humanity. The Policlinico, the building in which the Congress convened, was well adapted for the purpose. In it eighteen sections daily convened and all the national committees assembled simultaneously. It consisted of a series of eight large, two-storied, lofty pavilions, with superb marble stair-ways, large windows and porticos, and immense areas or courts for light and ventilation. It is intended, as its designation intimates, to be the principal Infirmary and centre for teaching for all Italy. Its capacity when complete will be for about fourteen hundred beds, which, with the extensive laboratories and spacious operating-theatres and lecture-rooms, will be one of the best-equipped institutions for teaching in all Europe.

The only possible objection to it, as a visiting place, was its distance from Piazza-Colonna, or the centre of the city—about two miles—and because of its newness it was yet rather damp and chilly.

The language most generally spoken at the Congress was French. All the Italian doctors seem to have a speaking knowledge of this tongue, and even the Spaniards from South America could make themselves readily understood, through its employment. German came second, although the Germans did not attend in very large numbers. English came in a poor third; and he whose linguistic capacity was limited to this language, was at a great disadvantage. It might be stated, without fear of over-stating the truth, that English-speaking readers were barely tolerated. Essayists who read English or discussed contributions, were restrained within the severest limits; while the French, Italians and Germans had *carte blanche* and consumed as much time as they liked. Perhaps the Romans were not so much to blame for this, as the French element was there in great strength, and seemed to vastly predominate in influence. Moreover, there seemed to be a disposition on the side of both Italians and French to re-establish the old *entente cordiale* so long interrupted.

The attendance from the United States was not large, nor representative of the leading members of the profession. This, no doubt, was attributable to the season of the year, when all the schools were in session, and many famous teachers were unable to be present. In the committee rooms of the American delegation, however, one hundred and seven registered; the greater number of them being from the West and South. But our army, navy and marine-hospital services were amply represented by medical officers of advanced rank, who attended the sessions in full uniform.

The general sessions were held in the Eldorado on the via Genova, every afternoon during the five days of the Congressional sessions, at three in the afternoon. Here, only on the last day, was America accorded the privilege of entertaining the assembled multitude with a public address. This was presented by Dr. Abram Jacobi of New York, whose effort was well worthy of the distinguished speaker and the country of his adoption.

As might be expected, the scientific portion of it dealt chiefly with the maladies of children; but, as he proceeded, he considered the present status of the healing art in the United States, and dealt the over-specializing tendencies of modern times some crushing blows. The reckless, useless mutilations so often practised, at present, as current operations, he declared were little short of murder; and he anathematized the performers of them as those whose hands were so stained that no amount of sterilization could purify; and whose souls were so corrupted that no chemical fluid could preserve or restore them. Modern antipyretics he declared had killed more than they cured, and the profession was responsible for the position which proprietary medicines occupied.

One feature of the Congress, of interest to Americans, and which did good service for our scattered delegates, was the organization of the American Delegation, in Section C of the Polyclinic. Here the delegates from the United States and Canada organized a bureau for information, with Dr. Abram Jacobi for President, Dr. Thomas H. Manley, of New York, Dr. William Tobin, of Halifax, and Dr. G. A. Simmons, of Sacramento, Cal., as an Executive Committee, and Dr. Douglas H. Stewart, of New York, as Secretary.

During their second day's session the delegation was visited by the American Ambassador to Italy, the Hon. Wayne McVeagh, who made a short address, in which he declared that it afforded him great pleasure to meet the American contingent. He bespoke for them a hospitable reception from their Italian *confrères*, and reminded the delegates that he would be ready to serve them at any time during their stay, by every possible means within his power.

In conclusion it may be said that while the late Congress did not in every particular fulfil all that was expected

of it, yet, considering the many difficulties in the way, the anticipations of the majority were more than realized. At all events, when it is remembered that the English, French and Italian railways reduced their travelling rates for passengers fifty per cent., and that an opportunity was permitted to visit the principal cities and hospitals of Europe *en route*, the time consumed by the Americans was not mispent, and they will return to their homes with renewed energy after their short holiday, and all the better equipped for the duties which await them on their arrival.

UN VOYAGEUR.

THE PROPOSED REDUCTION IN THE ARMY MEDICAL SERVICE.

GROVELAND, MASS., April 10, 1894.

MR. EDITOR:—I noticed your correspondent's anonymous communication (April 5, 1894), signed "Medicus," concerning the "Proposed Reduction of the Army Medical Corps," with a secondary title, "An Attempted Legislative Outrage!" I do not like to reply to, or even notice, any communication in which the author, for certain reasons best known to himself, conceals his name.

The statement concerning acting assistant-surgeons, which title pleases not your grumbling incog. (who is probably a member of the Medical Corps) that "there is no provision of law whereby they (acting assistant-surgeons) can be placed in charge of the medical department at a military post," is either a malicious lie or an ignorant assertion of erroneous views. In either case it is untrue. There are some younglings, bursting with importance, who know little of military medical history in this country, particularly during the late Civil War, who *pretend* to imagine that by scorning acting assistant-surgeons as "contract-doctors" they in some measure increase their own prominence. It would take too much of your time to name hundreds of prominent medical men who were once acting assistant-surgeons to the United States Army. These and their associates have all "been placed in charge of the medical department at a military post" time and again. Some have served as acting medical directors of a department, some in charge of large hospitals, camps, transports, etc. Some preferred capture in battle rather than to desert their wounded. If "Medicus" will read the records of the Association of Acting Assistant-Surgeons, United States Army, he will learn the history of many medical men who have become eminent in medical history, and whose position socially and professionally is *equalled by few* of the so-called regular officers of the medical department, who are so well paid and yet have so little to do.

Prominent generals of the army and prominent members of the army medical department have gladly offered their testimony in favor of the bill for the acting assistant-surgeons which has been lately presented to Congress. Your own kindly notice of the Association of Acting Assistant-Surgeons in a recent number of the JOURNAL reflects the best professional opinion concerning them.

For some years an influence has been exerted by a selfish clique, under the leadership of the Surgeon-General's Office, to make the way of the acting assistant-surgeon a hard road to travel. Any one acquainted with the true facts must have seen how pernicious and unmanly this influence has been. The acting assistant-surgeon has invariably accepted the duties of military medical life with the miserable pay offered, and he has also known the perilous detail, when the more favored surgeon remained comfortably at home and received the extra fees from outside practice.

In my opinion, the sneers and misinformation contained in the communication of "Medicus" are unwarranted, unkind and ungentlemanly, and deserve to be disapproved of by all medical men. I have known the acting assistant-surgeons for over a quarter of a century, and I have always found them faithful, competent and honorable, deserving a much better status. It is very remarkable that members of a medical corps so well paid (much better paid

than the medical officers of any other army) should attempt to persecute reputable medical officers who perform the same duties, and with exactly as much skill as the more favored members of the so-called Medical Corps.

Little can be hoped for, so far as justice is concerned. Acting assistant-surgeons who have faced the perils of Indian warfare are just as much heroes as those who served in the war of the Rebellion. An acting assistant-surgeon is peer of any medical officer, and from real men and true gentlemen receives every courtesy.

Yours truly,

W. THORNTON PARKER, M.D.

NEW YORK, April 15, 1894.

MR. EDITOR:—In a recent number of the JOURNAL I called attention to the legislative outrage now being attempted in Congress of cutting off from the Medical Corps of the Army thirty-five of its members, on the buncombe plea of economy, and in spite of the strenuous objections of the Surgeon-General, Dr. Sternberg, and the commander-in-chief of the United States Army, Gen. J. M. Schofield, both of whom have clearly shown that these men are really needed. As General Schofield put it in a letter to the Secretary of War, dated March 15, 1894, this pending bill would be "seriously injurious to the military service"; also, "the Medical Corps of the Army is none too large for the necessities of the service."

I am therefore surprised that any self-respecting doctor could write in defence of this measure, so utterly unworthy of support. Indeed, not alone the *Boston Medical and Surgical Journal*, but following it, the *New York Medical Journal*, the *Philadelphia Medical News*, the *New York Medical Record*, and many more of the most influential and able medical publications of this country, have recently published vigorous editorial denunciations of this insult to our profession: a measure which, if successful, will result at once in stopping the working of the new Army Medical School, which, under General Sternberg's able lead, is doing such scientific work among the younger surgeons in the army, educating them in sanitation of military hospitals and troops, commissary knowledge, bacteriology, military surgery, etc.

The tone, the evident animus, of the gentleman who has seen fit to honor me with his attack deprives his letter of weight, even aside from its misstatements. Nevertheless, let me point out to your readers, Mr. Editor, the fact that he seems to regard this bill as one which, if it passes, dropping thereby thirty-five regular medical officers, will enable contract-doctors to take their places; and he looks upon my letter as an onslaught against contract-doctors in general, whom he proceeds to defend.

There is not a line, not a word, in my letter to justify this excited rhetoric.

What I said in this context is as follows: "There is now no appropriation made for contract-doctors, though formerly this was the case; and even if there were, *there is no provision of law whereby they can be placed in charge of the medical department at a military post*. Therefore, they cannot take charge of the discipline and field-drill of the Hospital Corps detachment, nor be responsible for the post-hospital with its supplies. To effect economy as far as practicable, the Surgeon-General has long employed only private physicians at all the arsenal-posts in the country, these being small ones."

The doctor attacking my letter denies the truth of the statement which I have put in italics, and becomes vituperative thereupon regarding my ignorance.

Let me reply that this statement was made by me upon authority of the words of the Surgeon-General himself. Indeed, every figure, every assertion in my letter was absolutely accurate, having been furnished me by one of the medical officers of highest rank in the army, and with a view to publication.

Whatever powers the contract-surgeons had during war times, the fact as to the law *to-day* is precisely as stated in my letter. If this gentleman who went off at half-cock, and loaded only with blank cartridge, will apply to Sur-

geon-General Sternberg for much-needed information, every word that I have stated will be corroborated.

In conclusion, Mr. Editor, allow me to say with reference to the remarks on anonymous contributions, that you were furnished with my name, and had you seen fit, could have signed it to my letter. Very properly, you did not regard my own personality as one that had anything to do with the question at issue, which is not a personal matter, but one affecting the well-being of forty-three thousand soldiers and civilians in the army, with their wives and children, and also involving the self-respect and dignity of the noblest of professions.

Very respectfully,

ROBERT H. M. DAWBARN, M.D.,
105 West 74th Street.

PERFORATING WOUND OF THE HEART.

BALTIMORE, MD., April 20, 1894.

MR. EDITOR:—Seeing a case reported in the JOURNAL from California, where a pistol-ball went through the heart and the man lived thirteen hours after the injury, reminds me of a case which I reported to the Baltimore Clinical Society in the year 1889.

It was that of a woman, age about twenty-two years, who was stabbed and thrown from her husband's knee to the floor. She died six days and fifteen hours after receiving the wound and the blow. It was shown post-mortem, ten hours after death, that a wound in left breast to the right of left nipple, between the third and fourth ribs, passed through the pericardium, making a slit one inch in length. In the pericardium, two tablespoonfuls of partly-clotted blood were found. The wound then entered the right ventricle a little to the right of the ventricular septum, passing entirely through the anterior portion of the ventricle, being about a half-inch long on its outer aspect and about one-quarter of an inch on the inner side. On the outer side of the heart there was a thin layer of lymph, and through the opening made in the heart there was a solid plug of lymph extending somewhat into the heart. A very small quantity of fluid blood was found in the heart. The blow brought on an abortion, as she was between two and three months pregnant, and she eventually died of septicæmia. She was jaundiced, liver was fatty, mesentery and serous coats of the bowels were of a golden hue, and there was peritonitis. The point that I made in my paper was that, had it not been that the woman was pregnant, she would have undoubtedly recovered from the stab-wound through the heart, as nature was making every effort to heal the breach. Hence I say that stab or pistol wounds into the heart are not necessarily fatal, as the records from the history of the late war will show.

Yours truly, R. M. HALL, M.D.

METEOROLOGICAL RECORD.

For the week ending April 14th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Newburyport	14,073	6	1	—	—	—	—	—
Amesbury	10,920	1	0	—	—	—	—	—

Deaths reported 2,536; under five years of age 888; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fever) 340, acute lung diseases 453, consumption 296, diphtheria and croup 142, scarlet fever 42, diarrhoeal diseases 38, measles 37, whooping-cough 30, typhoid fever 17, small-pox 16, cerebro-spinal meningitis 14, erysipelas 4.

From small-pox New York 7, Brooklyn 6, Boston 3. From measles New York 16, Brooklyn 10, Philadelphia and Cleveland 5 each, Northampton 1. From whooping-cough New York 10, Philadelphia and Brooklyn 6 each, Boston 3, Cincinnati, Nashville, Lowell, Everett and Hyde Park 1 each. From typhoid fever New York and Philadelphia 5 each, Cincinnati 3, Brooklyn, Washington, Lynn and Haverhill 1 each. From cerebro-spinal meningitis New York 9, Boston, Washington, Worcester, Somerville and Pittsfield 1 each.

In the thirty-three greater towns of England and Wales with an estimated population of 10,488,442, for the week ending April 7th, the death-rate was 19.6. Deaths reported 3,923: acute diseases of the respiratory organs (London) 314, measles 210, whooping-cough 148, diphtheria 80, scarlet fever 39, diarrhoea 29, fever 28, small-pox (Birmingham 4, London and West Ham 2 each, Bradford 1) 9.

The death-rates ranged from 12.7 in Brighton to 27.4 in Salford; Birmingham 23.0, Bradford 15.1, Bristol 18.9, Croydon 16.3, Hull 17.9, Leeds 20.5, Leicester 14.9, Liverpool 25.3, London 19.0, Manchester 21.6, Newcastle-on-Tyne 22.2, Nottingham 18.4, Portsmouth 16.5, Sheffield 18.5.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 14, 1894, TO APRIL 20, 1894.

FIRST-LIEUT. ALLEN M. SMITH, assistant surgeon, will be relieved from duty at Fort Custer, Montana, at the expiration of his present leave of absence and will report in person to the commanding officer, Fort Reno, Oklahoma Territory, for duty at that post.

FIRST-LIEUT. JAMES M. KENNEDY, assistant surgeon, is relieved from duty at Fort Riley, Kansas, and ordered to Fort Custer, Montana, for duty.

By direction of the President, CAPTAIN ALONZO R. CHAPIN,

assistant surgeon, will report in person to the president of the Army retiring board at Fort Bliss, Texas, for examination by the board.

The leave of absence granted CAPTAIN OGDEN RAFFERTY, assistant surgeon, is extended eighteen days.

FIRST-LIEUT. CHARLES WILLCOX, assistant surgeon, is relieved from temporary duty at Angel Island, Cal., and will rejoin his proper station, the Presidio of San Francisco, Cal.

Par. 2, S. O. No. 68, A. G. O., is so amended as to direct FIRST-LIEUT. HARLAN E. MC VAY, assistant surgeon, on being relieved from duty at San Carlos, Arizona Territory, by FIRST-LIEUT. STRAUB, assistant surgeon, to report for duty at Angel Island, Cal., instead of Fort Huachuca, Arizona Territory.

So much of Par. 13, S. O. No. 79, A. G. O. as relates to MAJOR PETER J. A. CLEARY, surgeon, is so amended as to direct him on being relieved from duty at Fort McPherson, Georgia, to report for duty at Fort Wingate, New Mexico, instead of Fort Custer, Montana, for duty at that post, to relieve MAJOR WASHINGTON MATTHEWS, surgeon.

MAJOR MATTHEWS, on being so relieved, will repair to Washington City and report in person to the surgeon-general for temporary duty in his office.

PROMOTION.

CAPTAIN JAMES C. MERRILL, assistant surgeon, to be surgeon with the rank of Major, March 13, 1894, vice BARTHOLOMEW retired from active service.

SOCIETY NOTICES.

THE SUFFOLK DISTRICT MEDICAL SOCIETY, SURGICAL SECTION. — The Surgical section of the Suffolk District Medical Society will hold its regular monthly meeting on Wednesday evening, May 2d, at 19 Boylston Place, at 8 o'clock.

Dr. M. H. Richardson will make a report of "Cases of Intestinal Resection with Subsequent Suture of the Bowel."

CHARLES L. SCUDDER, M.D., *Secretary*.

SUFFOLK DISTRICT MEDICAL SOCIETY. — The annual meeting will be held at 19 Boylston Place, on Saturday, April 28, 1894, at 8 P. M.

Papers. Dr. F. S. Watson, "Some of the Clinical Features and the Surgical Treatment of Primary Tuberculosis of the Urinary Organs." Discussion by Dr. P. Thorndike and others. Dr. F. H. Williams, "Diphtheria." Dr. W. A. Morrison, "The Value of the Stomach-Tube in Feeding after Intubation" — based upon twenty-eight cases. Discussion by Dr. F. B. Harrington, Dr. Gannett, Dr. C. M. Whitney and Dr. Prescott.

Business. Report of the treasurer and the librarian. Election of officers. Appointment of delegates to the American Medical Association.

Supper after the meeting.

A. L. MASON, M.D., *President*.

JAMES J. MINOT, M.D., *Secretary*.

AMERICAN PEDIATRIC SOCIETY. — The American Pediatric Society will hold its sixth annual meeting at Washington, D. C., May 29, 30, 31 and June 1, 1894. The sessions will be held at the Arlington.

AMERICAN DERMATOLOGICAL ASSOCIATION. — The eighteenth annual meeting of the American Dermatological Association will be held at the Arlington Hotel, Washington, D. C., May 29, 30, 31 and June 1, 1894.

The general session of the Congress will be held at 3.30 P. M. on May 30th, the subject for discussion being "The Distribution and Control of Leprosy in North America."

R. B. MORISON, M.D., *President*, Baltimore.

C. W. ALLEN, M.D., *Secretary*, New York.

ASSOCIATION OF AMERICAN ANATOMISTS. — The sixth annual meeting of the Association of American Anatomists will be held in connection with the Congress of American Physicians and Surgeons, May 29 to June 1, 1894, in the city of Washington, D. C. This will be the first meeting since that of December 27 to 29, 1892, at Princeton, N. J. The sessions will be held in the Preparatory Department of the Columbian University.

HARVARD MEDICAL SCHOOL.

EVENING LECTURES.

The next lecture will be given on Wednesday evening, May 2d, at 8 o'clock, by Assistant Professor T. M. Rotch. Subject, "Infant Feeding." Physicians are cordially invited.

RESIGNATION.

DR. JOHN LOVETT MORSE, has resigned the position of Registrar at the Carney Hospital.

THE MIDDLETON GOLDSMITH LECTURE.

The Middleton Goldsmith Lecture of the New York Pathological Society for 1894, will be delivered at the New York Academy of Medicine on Saturday, April 28th, at 8.30 P. M., by Prof. William H. Welch, of Johns Hopkins University. Subject: "Mixed and Secondary Infections."

RECENT DEATHS.

WILLIAM V. KEATING, M.D., died in Philadelphia, April 19th, aged seventy years.

DAVID CRABY, SR., M.D., died in Hartford, Conn., April 16th, aged eighty-eight years. He graduated from the Medical College at Castleton, Vt., in 1834, and had practised in Hartford since 1838. He was present at the first administration of ether by Dr. Wells and had attended over three thousand cases of childbirth. He was a member of the Connecticut Medical Society.

DR. FRITSCHI, Privat-docent in the University of Freiburg, and the oldest privat-docent in Germany, died recently, aged eighty-two years.

F. W. WEBER, M.D., Ph.D., died at Nieheim, Westphalia, April 5th, aged eighty-one years. Besides his reputation as a physician in his own province he was one of the best-known poets of the present time in Germany, and for thirty-two years represented his district in the Prussian Landtag.

JEAN EDOUARD JUHET-RENOY, M.D., one of the ablest of the younger physicians of Paris, died in that city, March 19th, aged thirty-nine years. He was physician to the Hôpital Cochin and had contributed many articles to medical literature, especially in the "Dictionnaire de Médecine et de Chirurgie" and the "Dictionnaire Encyclopédique des Sciences Médicales." By a curious fatality he died of typhoid fever contracted from a patient while preparing a paper on the treatment of that disease to be read at the International Medical Congress in Rome.

HENRY SMITH, F.R.C.S., England, Emeritus Professor of Surgery at Kings College, London, died at Summerhill, Horehill, Surrey, March 25th, aged seventy years. He was, in his earlier days, assistant to Sir William Ferguson, and was consulting surgeon to Kings College Hospital and at one time President of the Medical Society of London. Following Ferguson's lead he gave great attention to advocating a more conservative treatment of bone and joint disease than the then too common amputation. His chief surgical reputation, however, was made in the department of diseases of the rectum and he will be long remembered as the introducer of the clamp and cautery treatment of hæmorrhoids. He was Lettsomian Lecturer in 1866 and chose as his subject "The Surgery of the Rectum." He was an ardent lover of natural history and a most enthusiastic fisherman, his clinical and didactic lectures on surgery being constantly interspersed with anecdotes and illustrations from his favorite sport.

BOOKS AND PAMPHLETS RECEIVED.

A Modern Wizard. By Rodrigues Ottolengui. New York: G. P. Putnam's Sons. 1894.

Report of the Jefferson Medical College and Hospital for the Year ending September 30, 1893.

Laparo-Hysterotomy: Its Indications and Technique. By N. Senn, M.D., Ph.D., LL.D. Reprint. 1893.

THE AFTER-TREATMENT OF OPERATIONS FOR APPENDICITIS.¹

BY HERBERT L. BURRELL, M.D.,

Instructor in Clinical Surgery, Harvard Medical School; Surgeon, Boston City Hospital.

THE following details and questions have presented themselves to me in the after-treatment of operations for appendicitis:

(1) The method and material to be used in securing the stump of the appendix. While, strictly speaking, the treatment of the stump of the appendix is a part of the operation, yet I shall speak of the method and material to be used as I believe it influences the treatment. I have been in the habit of using silk, and in the majority of instances it has been satisfactory; but it is occasionally open to the objection that it becomes a foreign body in the wound and may be cast off after a time, varying from weeks to months, and has made a troublesome sinus and required (in one or two instances) curetting under ether in order to remove it. While we may use silk which is perfectly aseptic it is, of course, immediately contaminated by foul septic fluids, and hence does not become organized. Catgut of sufficient size has seemed to me to be equally efficient in holding the stump of the appendix, and only occasionally have I found it necessary to use interrupted Lembert sutures to invert the peritoneal surfaces covering the stump of the divided appendix. In fact, wherever time has been of great importance I have simply thrown a ligature around the end of the appendix close to its origin, and have cut away the remaining end. In operations where there is but little pus I see no objection to using silk, but where there is a good deal of pus until I see some reason to change my method I shall use catgut in securing the stump of an appendix.

(2) Closure of the wound. I think that all surgeons would agree that the best time to operate upon an appendix is between the attacks. At this time we have a wound free from pus, and while the appendix is difficult at times to isolate, yet having once secured and removed it a clean wound is left, which can be sewed up and the patient left with but little anxiety. In several instances where I have operated between the attacks I have been surprised to find a few drops of pus, and in one instance I found while operating between the attacks, the patient having been about for some time after the previous attack, a fecal concretion the size of a cranberry bean, which was loose in the peritoneal cavity. There was also a minute perforation of the appendix. These conditions would contaminate the wound unless the septic material were removed mechanically, and the cavity rendered relatively sterile. Where time is an object I have used sutures transfixing the abdominal walls. Where the wound could be closed at leisure I have used three lines of sutures, one in the peritoneum, one in the transversalis fascia and muscles, and the third in the skin. These have usually been of silk of small size, although I prefer silkworm-gut.

(3) The treatment of shock following operation. In addition to alcoholic stimulants, brandy, whiskey, etc., heaters and rectal enemata of brandy, atropia

(1½ gr.), strychnia (½ gr.) and digitalin (1½ gr.) have been used subcutaneously to much advantage in the critical cases.

(4) The feeding of patients. I have given patients only cracked ice, beef tea, and a little milk for the first twenty-four to forty-eight hours. Opiates are used freely, for I believe that the patient loses more from suffering pain than he gains by the free action of the intestines from saline cathartics. I am sure that in one instance by the use of saline cathartics I turned the scale against the patient's recovery.

The vomiting which follows operations of this description I have treated by morphia, one-eighth to one-quarter of a grain doses, combined with cracked ice, siphon of soda and champagne. Not infrequently I have withheld all food by mouth, and have depended entirely upon nutrient enemata for from twenty-four to forty-eight hours where vomiting has been a prominent symptom. Occasionally the white of an egg has been retained where other substances have been rejected. In one instance at the end of three days where the vomiting continued I washed out the stomach with the result that the vomiting ceased. If, however, the vomiting continues beyond the third or fourth day I have usually regarded the case as hopeless.

(5) The indications and contra-indications for the use of saline cathartics. These I have used freely, and whenever there has been any rise in temperature after the first forty-eight hours, any increase in the frequency of the pulse, or a glazing of the tongue, I have used a saturated solution of salts in teaspoonful doses, or even in half-drachm doses, combined with soda water from a siphon, the drink to be given very cold. When there is any tendency to vomiting I have used half-drachm doses of the saturated solution of salts combined with a siphon of soda water, the drink to be given very cold, every hour. Occasionally where there has been vomiting I have used a saturated solution of salts by enema with excellent results, and at times a glycerine suppository enema combined with the saline enema has been efficient in establishing intestinal drainage, and I am convinced that while saline cathartics are of great value in producing intestinal drainage in septic peritonitis, yet the withholding of morphia in order to attain the full action of the salts is at times unwise. I can see no reason why opiates and saline cathartics should not be given at the same time. Of course, we must recognize that they counteract one another, but I have found that in using them in conjunction with one another I have obtained the benefits of each.

(6) The kind, amount and frequency of irrigating fluids to be used. I feel safer in mechanically flushing out with sterile water or boracic-acid solution a cavity of an appendicitis operation than I do in using solutions of corrosive sublimate. In one instance where there was a small amount of pus and a septic condition of the surrounding tissues the wound was cleansed thoroughly with hydrogen di-oxide (50 volumes), and then the septic purulent surfaces were touched with the actual cautery and the wound sewed up; but it had to be reopened on the fifth day in order to evacuate pus. This case, however, recovered very rapidly after the wound was dilated and irrigated, and at the end of six weeks the wound was completely healed and the patient up and about. It has seemed to me that it was better to depend upon flushing with sterile water than to rely upon the germicidal action

¹ Read before the Boston Society for Medical Improvement, February 12, 1895.

of antiseptics in the removal of septic material from an appendiceal wound.

The question of how frequently to irrigate a wound depends upon what kind of material is used to drain it. When there is a temperature above 101° after the third day I have usually irrigated frequently and freely, sometimes every four or six hours during the twenty-four.

(7) The next three questions may be discussed together. They are, when to drain and not to drain; what material to use as a drain, whether tubes, gauze or rubber dam; and how long to drain.

If there is no pus in the abdomen, of course the wound is closed. I have found that when there is a slight amount of pus in the wound, where the cavity can be completely cleansed, one can safely close it. However, it is safer to err on the side of drainage than non-drainage.

Whether to use iodoform gauze, rubber-dam or rubber tubing has been to me an important question. Rubber tubes, I believe, are indicated where there is a large pus cavity with walls which do not collapse; rubber-dam or iodoform gauze are indicated where the cavity is collapsible; where the intestines fall into the abscess cavity the gauze can be insinuated into nooks and corners and crevices which a tube can never reach. I am sure that it is wiser to use gauze than to use tubing in those cases of early operation for appendicitis where the appendiceal inflammation is not walled off. Where in doubt, and yet where I have closed the wound, I have placed between the edges of the wound a narrow strip of iodoform gauze or rubber-dam, which I have removed on the third or fourth day if it were not found necessary before. The cases which I always feel demand iodoform gauze are those where in operating within forty-eight hours from the beginning of the attack a perforated appendix is found, especially when it is a question whether the general peritoneal cavity is invaded.

In these cases I have left iodoform wicks in for weeks at a time, gradually withdrawing them until every vestige of septic material was removed from the wound by washing with boracic acid or sterile water.

How long to drain is a question that has never been settled in my mind. When the temperature reaches to normal, and when there ceases to be an evening rise in temperature, I usually remove a few of the iodoform wicks or the tube. The wound is, of course, irrigated out daily, and if there is much discharge iodoform is dusted over the open wound. It has been my practice where I removed an appendix, — and I never feel satisfied that I have given the patient the best chance unless I have removed the appendix, — to carry the iodoform gauze down to the stump of the appendix, believing that if this could be covered by granulation tissue a firmer cicatrix would be gained, and less liability to hernia would exist.

As a rule, I have been inclined to remove the drainage too early, judging alone from the wound, and in my later cases have come to depend upon, not alone the condition of the wound, but the patient's temperature, pulse, and the condition of the general peritoneal cavity, whether showing evidence of inflammation or not.

(8) The indications for reopening a closed wound or for exploring an open wound following an appendix operation. To reopen a closed wound offends one's surgical sense, but to allow a patient to die from septic

absorption from defective drainage is, to put it mildly, very unfortunate. On the other hand, to explore an open wound following an appendicitis operation is a thing that I have been led to do in a number of instances. I always think of doing it whenever there is a continued rise in temperature after the fifth day or a chill, where a wound tends to gape, or from which pus flows, a drachm at a time, at indefinite intervals; and whenever there is associated with it evidences of infection of the general peritoneal cavity I believe that the patient should be etherized, the wound carefully explored with the finger, and any pocket of pus or septic material that is loose should be washed out thoroughly. I am sure that this is an important thing to do, and a moment's thought must make it clear that a cavity filled with coils of intestines is very difficult, and at times almost impossible, to free from septic material at the time of operation.

In three instances last summer, between the tenth and twelfth days, after the temperature had been normal, I was obliged to reopen wounds on account of a sudden and continued rise in temperature and chills. An abscess was suspected, but in none of these cases was an abscess found. On opening up the wound, however, and separating the coils of intestines, there escaped a large quantity of offensive gas. It was so marked that in one case a bystander said, "Why, there must be a perforation of the intestines." I suspect that this gas had something to do with the continued high temperature, for in each instance the wounds were repacked, the temperature fell to normal in a short time, and convalescence was established.

In one case I explored a wound on the tenth day, and found an abscess pointing toward the loin. A counter-opening was made in the back, a drainage-tube inserted and through-and-through irrigation established. Where the appendix rests high up in the loin, and where there is a large amount of pus, I am inclined to believe that this through-and-through drainage would at times be of great value.

In two instances I have had fæcal fistulæ develop, but by thoroughly cleansing (by irrigation) the wound it has been possible to bring about a complete, although delayed closure of the wound.

I have presented these questions in the after-treatment of this operation as they have occurred to my mind. There is, of course, room for difference of opinion, and it is impossible at present to lay down principles in the after-treatment of this operation; but I am sure of one principle, and that is, that when we are in doubt the wound and abdomen should be freed from all septic material.

THE PRODUCTION OF VACCINE VIRUS.¹

BY D. D. GILBERT, M.D., CHAIRMAN, DORCHESTER, MASS.

YOUR committee have visited the two principal depots from which the vaccine stock is supplied to this section, namely, the New England Vaccine Company's operating-rooms in Chelsea, and the operating-rooms of the late Henry A. Martin, M.D. We were welcomed with gentlemanly courtesy and attention at both places, where the processes were freely shown and explained. We have also had freely given from Codman & Shurtleff a description of the process pursued by

¹ The report of a committee appointed by the Norfolk District Medical Society to investigate the production of vaccine virus.

them at their farm in Stoughton, which we were cordially invited to visit. Also, I will state that, at the meeting of the Norfolk District Society where this report was originally made, Dr. Francis C. Martin made some remarks in regard to the course pursued by him at his establishment.

At Chelsea we found buildings well adapted for the purpose—a stable so built with cemented floors, gutters and walls, that it could be thoroughly flushed; and it had evidently so been, for not a particle of stable *débris* was present. Leading from this stable, separated by an entry and double-doors, is the operating-room proper. This room has a floor of artificial stone, tiled walls, and is heated by steam. It is furnished with sets of stanchions in which to securely and comfortably confine the cattle undergoing the operations, and with a closet of fine-wire gauze, for the drying of the freshly charged points, admitting the air but excluding the coarser particles of dust. This room can also be thoroughly flushed, and it is claimed that it is so treated with antiseptic solutions from time to time. There is an evident intent to preserve the appearance, at least, of asepsis, but one notices a carelessness of the employés in handling the charged points, etc., with hands which are certainly not surgically aseptic. Whether this comes from ignorance of what science has a right to demand in such a process, or whether it is the carelessness which familiarity with routine work almost necessarily begets, I do not know. In regard to the results I will speak later.

The operating-room at the Martin establishment is an ordinary room opening directly from the carriage-house of the stable. This room has wooden floor and walls, and has no conveniences whatever for producing aseptic conditions other than such as accompany ordinary cleanliness. Mr. Reed told us they made no pretensions to do more.

The process of securing the lymph at the two establishments differs in many ways. At the New England, they use mature animals, about four years old. These are vaccinated on the back of the buttocks, in about a dozen large confluent patches, three to four inches square. At the Martin establishment they use immature animals, preferably under one year of age. These are vaccinated on the back of one buttock and on one side of the belly, in small patches about three-fourths of an inch square, which do not materially enlarge in development. At the New England establishment the animal while undergoing operation remains standing, confined by a set of stanchions. At the Martin establishment the work is done upon the animal lying on its side, and strapped to a table. At Codman & Shurtleff's, and at Dr. Francis C. Martin's, the age of animals and the process are practically the same as at the Martin stable in Brookline.

Dr. Perry, of our committee, has kindly prepared some rough diagrams which will give you a better idea of how the animals are vaccinated than will any verbal description.

Mr. Reed, of the Martin establishment, claimed that the advantages of using young animals are the lesser danger of their being diseased, and the greater facility of handling them. At the New England institute there seems to be no difficulty of handling the animals with the facilities which they have, and each animal before it is taken into their stable has been examined by a veterinary surgeon, and a certificate of its healthy condition issued to the company. This cer-

tificate is numbered, and the cow is tagged with a corresponding number which is recorded. By means of this system of numbering the company are able to know from what animal any issued points have been taken. The same system of numbering, but not of veterinary examination, is pursued at the Martin establishment. Codman & Shurtleff have all their animals examined by a regular physician, and a record of each animal is kept.

At the first glance at the animal vaccinated and ready for use, the sight is repulsive, and the broken-down, suppurating crust seems a most disagreeable thing to inoculate into the human organism. These crusts and their accompanying *débris*, you are told, are ground up with glycerine and regularly dispensed as vaccine stock in some foreign countries. Here the crust and all loose tissue are removed, thus exposing the base of the vesicle. At the New England institute, this, with the surrounding skin, is thoroughly washed with a sponge and clean water, and after a few minutes the serum exudes and, the animal standing in an upright position, trickles down to the lower edge of the patch from which it is taken upon the points. The first flow is a little discolored with blood, and is kept to revaccinate new animals with. After a while the flow of serum is obtained perfectly clear and of a slightly yellowish shade. By this method, at the New England institute, the points are not brought at all in contact with the raw surface but receive the lymph as it trickles down to the sound skin. The points are then laid upon a nickel-plated metal tray, channelled and adapted for the purpose. When the tray is filled, it is placed inside the gauze closet to dry.

At the Martin establishment, as I have said, the vesicles are individually smaller, and, after having been freed from the crust, are not washed but are wiped with a towel which seems to have done some service in the same direction before. From these vesicles, there being less tension of the tissues than where the patches are larger, the lymph does not exude itself but is squeezed out by compression of the base with forceps, and the points are charged directly from the denuded surface; therefore all are more or less discolored with blood. At the New England establishment the points having been received from the factory are sterilized before being charged—subjected for an hour to a temperature of 212°. At the other place, as I have said, no attempt at asepsis is made.

At Codman & Shurtleff's establishment the process is similar to that at the Martin, except that, instead of dipping the points into the lymph exuding from the raw base of the vesicle, the lymph is collected in little glass cups, and any *débris* present in it is allowed to settle or is skimmed off, after which the points are charged with the clear lymph.

Now, while neither of these processes approach what we know as surgical asepsis, yet the fact remains that we never hear of septic inflammation setting in within a few hours after vaccination, which it surely would do if septic matter were directly introduced into the system; so that we must believe that the charged points are not septic even if the process of preparing them is not ideal.

On the other hand, when suppuration does occur, it sets in as a secondary result to the mature vesicle. This it is claimed, and justly it would seem, is due to atmospheric germs having found their way within the ruptured capsule of a broken vesicle. Therefore, when

this occurs in this secondary manner, it is after the vaccinia has been produced, and it does not, as is sometimes claimed, interfere with the protective power of the vaccination. The resulting sore should therefore be treated antiseptically from that time on, and healed as soon as possible.

Dr. Cutler, at the head of the New England establishment, maintains that a small vesicle should always be obtained, and that, from the commencement, it should be kept as dry as possible, no moist or oily dressing ever being used. A small vesicle produces less inflammation — and so less necrosis of subjacent tissue, less areola, and so less constitutional disturbance. Moreover, it is far less liable to crack and rupture. He claims that the size and accompanying characteristics of the vesicle may be absolutely determined by the size of the original scarification, which had better be a mere puncture, and never should exceed one-sixteenth of an inch in diameter. There should be two or three of these vesicles situated nearly two inches apart, so that they may never become confluent with one another. He exclaimed, "It was a bad day when we were taught to scarify instead of the old-style puncture." His explanation of this and of his theory that a large scarification makes a confluent and highly inflamed vesicle is, that, while it is necessary to spread the inert virus obtained from calves over a large scarification, to get any result — uncertain at best — the lymph obtained from mature animals is richer in germs which become implanted all over the scarification and start numerous colonies, each a nucleus of vesicles which, as they grow, coalesce until they form the large confluent vesicle.

When a large confluent vesicle is produced in the human subject, the resulting cicatrix often fails to present the minute pits which the older vaccinators considered characteristic of successful vaccination, but this is really of no importance. In the human subject vaccinia produces a deeper inflammation than in the cow, and this fact, taken in connection with the high degree of inflammation produced by a large confluent vesicle, accounts for the necrosis of tissue which destroys the natural base of the vesicle with its characteristic pits. The simple appearance of a cicatrix affords no evidence as to the amount of protection. A cicatrix is only presumptive evidence of previous vaccination, and, if it is more than five years old, vaccination should be done in the presence of an epidemic. The only real evidence of protection is the insusceptibility to vaccinia under the most favorable conditions. Insusceptibility to vaccinia under such conditions is insusceptibility to variola. In the early history of vaccination some bold experiments were made at the small-pox hospital established by the Boston Board of Health at Noddle's Island, Massachusetts, by the way, was the first colony to introduce small-pox inoculation, and the first State to introduce kine-pox vaccination. "On August 16, 1802, 19 boys were vaccinated, and all passed through the regular stages of the cow-pox; and on November 9th following, 12 of them, together with the son of Dr. Bartlett, who had previously had the cow-pox, were inoculated for the small-pox with matter taken from a patient in the most infectious stage of the disease; and no trouble whatever followed." These facts are given in a report signed by eleven physicians, including Benj. Waterhouse and James Lloyd. A full and official account of the affair is found in the *Columbian Centinel*, December 18, 1802.

The formation of the areola is claimed to be the only test of constitutional or protective vaccination. If a person has been infected with small-pox, vaccination will not modify the disease unless the areola forms before the small-pox symptoms show. If, however, the stage of areola is reached before the symptoms of the graver disease appear, that disease will be aborted or modified by the vaccination.

Distinct, probably, from the various post-vaccinal eruptions which are sometimes called into activity by the excitement of vaccination, is a more or less widely distributed exanthem, or roseola, which is claimed to be simply a distributed areola, and need give rise to no anxiety, since it runs the same course as, and disappears with, the areola.

In conclusion, your committee are inclined to believe, from the limited observation which they have been able to make, that the New England virus is the more active and therefore the more dangerous virus to use; that the Martin virus is not as active and consequently may be the safer for general use. In reference to this, the New England people state that the danger of excessive result should not be laid at the door of active virus, which is necessary to fight an epidemic with, but is due to the ignorance of the proper technique of vaccination among some members of the medical profession, and especially among laymen who often do not hesitate to perform the operation. On the other hand, the late Dr. H. A. Martin has maintained that the serum from the large confluent vesicle on the cow, with its higher degree of inflammation, is alone responsible for the greater degree of irritation in the human subject. Your committee believe that these points can only be settled by a more careful attention, on the part of physicians, to the technique of the operation, and an observation of subsequent results.

Further, your committee are led to the positive belief that the whole subject of preparation of vaccine stock should not be left in the hands of rival commercial companies, but should be wholly under the official control of either city or State.

WHAT MIGHT BE DONE BY THE OBSTETRICAL SOCIETY TO ADVANCE THE TRAINING OF NURSES.¹

BY A. WORCESTER, M.D., WALTHAM.

IN the successful management of obstetric cases much depends upon the nursing service. Indeed, in normal cases, more depends upon the nurse than upon the physician. And in abnormal cases, especially where surgical interference is exercised, after the operation or the delivery is over, then even more responsibility falls upon the nurse for the happy uninterrupted recovery of the patient. If, to this is added the responsibility of starting a baby on a prosperous career of health and happiness, it would seem as if the monthly nurse always ought to be at least an angel. Sometimes she is one: sometimes she — isn't.

If obstetricians have poor or only tolerable nurses, it is their own fault: if they submit their patients to positively bad nursing service, then their fault is inexcusable. In other words, the physician is not blameless if his patient suffers from faulty nursing.

This particular responsibility of the doctor is of comparatively recent origin, and is due to the fact that

¹ Read before the Obstetrical Society of Boston, March 10, 1894.

within the last few years the profession of nursing has been revolutionized.

Monthly nurses used to be expected to know everything about mothers and babies. They did just as they pleased. They followed the suggestions of the physicians, if they saw fit to do so. Among these old-time nurses were many whose long experience, whose sterling common-sense and unflinching devotion entitled them to far greater rewards than they ever received. Some few of these old nurses or of their legitimate descendants may still be found in the old-fashioned households. But their type is fast passing from the stage.

In their place have come young women who have studied nursing. How contemptuously would the real old-timer have spoken of a *student* nurse! And how densely ignorant she would have seemed to the modern training-school graduate! Neither could understand the other. The revolution in nursing is complete.

With the old nurse the doctor's responsibility for the nursing service was very faint. She would brook but little criticism. Her unflinching defence lay in her silence. She would report only what she chose to report, and whatever happened she would never acknowledge her ignorance. Indeed, had she done so, her usefulness would have been abridged, for her families took comfort in her supposed infallibility. And much of the uncouth traditional household physiology and pathology of to-day has its origin in the speculations of the old monthly nurse.

With the modern nurse, on the other hand, the doctor's responsibility as to the nursing service is like that of the captain for the safety of his ship. Both are alike responsible for the execution of their orders. The modern nurse recognizes her position to be that of an executive officer: and when she is working under a physician who so recognizes her position, then all goes well. Where the modern nurse fails to give satisfactory service, the failure is generally due either to her improper training or to the inexact and unintelligible orders under which she was working. In either case the failure is primarily the physician's. For it is his business to train his nurses, or at least to secure trained-nurses for his patients, as it is also his business to give his directions in such exact intelligible fashion as will effectually prevent any misunderstanding.

Of course, it is possible that the failure of satisfactory service is due to the nurse's personal unfitness for her work; but, even so the physician is not free from accountability, for he ought to know the characteristics of his nurses and their fitness or unfitness for his different families and patients. The physician must apportion their service, just as a general must, by taking into account his subordinates' special fitness for various positions of responsibility. The personal equation nowadays is of constantly increasing importance. This is the age of specialists, and nurses equally good in all kinds of work and under all sorts of conditions are not to be found seeking employment.

If I am right in thus stating the responsibility now resting upon the medical profession as regards the nursing of their patients, it must be admitted that this responsibility is not generally acknowledged. Many physicians still scold about their nurses. Few take any pains to improve them, or take any interest in the methods of training. In short, the revolution in nursing has not yet penetrated the apprehension of such physicians.

My object in asking the attention of this Society to this subject is to enlist the coöperation of all who are interested in advancing the new movement. It is high time that concerted efforts should be made to secure, first, more trained nurses; second, better trained nurses; and, third, a more serviceable working relationship between doctors and nurses.

In this paper I purpose to consider especially the subject of obstetric nursing. Let us then, first, inquire how the supply of monthly nurses may be increased.

It is, of course, plain that the training schools of the lying-in hospitals cannot more than begin to supply the demand even of their immediate vicinity. When the birth-rate of the community is considered in comparison with the possible number of such graduates, it is only too apparent that not one out of every ten confinement cases can be so cared for.

Where the supply is so limited high wages rule, and only the rich can afford to employ trained nurses; accordingly physicians whose practice is mainly among the wealthy do not appreciate the scarcity. But women of moderate means, and of no means, need trained nurses just as much, if not more, than do their wealthy neighbors. Moreover, the physicians who attend such women in their confinements need the assistance of trained nurses.

The problem thus becomes one of economics at the very start. Its solution is not impossible. For just as is the case with physicians, so it should be with nurses: the poor now receive their medical attention at the hands of beginners or as a direct charity, and so they must receive their needed nursing service. Families of moderate means employ medical attendants who are willing to work for moderate fees. As these physicians and surgeons acquire greater reputation they take new patients only for increased fees, and so it goes on until only the very rich or those suffering from some pathological rarity can enjoy the privileged service of the very distinguished practitioners. So it must be with nurses. In a properly adjusted system of training, student nurses would practise, under the direction of their teachers, among the poor and those of moderate means. Immediately after graduation, instead of demanding at once the highest wages, they should expect to work for moderate pay among those who cannot afford more; and only after several years of increasing experience should trained nurses expect the highest wages.

At present the nursing profession in matters of compensation is too much like the clerical, where experience and proved usefulness count for little against youth and "brilliant promise."

It is, therefore, in this solution of the economic problem that we may discover how to increase the number of trained nurses. Not by increasing the lying-in hospitals, however desirable otherwise that may be, but by utilizing the opportunities for training that now surround us in the homes of the poor and of those moderately circumstanced. Thus, too, may be secured better nurses, and also that final desideratum—a more serviceable relationship between the two professions.

Until recently it has been held that nurses could be trained only within hospital walls. Whereas the truth is that nurses so trained begin their private practice under great disadvantages when compared with others, whose training has been in part in the private practice of their instructors. And in recognition of this fact,

many of the best training schools have already arranged to send out their student nurses to private work for a part of their training.

Meanwhile, the special problem before us is to arrange for the instruction in obstetric nursing of the hundreds of student-nurses and training-school graduates in this vicinity who now have no chance to learn the art. For, so long as our large training-schools graduate nurses, whose only instruction in obstetrics has been one or two lectures on the subject, we need not expect any spontaneous improvement. The graduates of these large schools may know how to manage a typhoid-fever patient, but many of them do not know a nipple-shield from a breast-pump; they, of course, do know how to arrange a room, and instruments and dressings, and the patient for an aseptic surgical operation, but they do not know how to prepare for ordinary obstetric cases. And yet, when they seek for private work, they soon find that surgical cases are not so common as confinements. Their general training, of course, helps them greatly in obstetric work if they bravely undertake it, but they have no opportunities hereabouts for instruction in this branch unless they enter the lying-in hospital courses, which at most could not accommodate one-tenth of those who should receive instruction before receiving their diplomas.

Physicians have to study surgery and obstetrics, even if they from the first intend to practise only as specialists in other branches. And it is accepted as axiomatic that some preliminary general practice is necessary to highest development in any specialty. Even more truly is this the case in the profession of nursing. No training should be considered complete that does not include obstetrics: nor should any obstetric nurse be considered as well trained who has not also been trained in the nursing of surgical and medical cases.

And yet the custom still prevails in Boston of training nurses only in specialties. Obstetric nurses, and nurses for infants, for lunatics, for neurasthenics, are graduated annually from various institutions; but very few nurses can be found who have received all of the different diplomas, and this in spite of the possibilities that neurasthenic women may have to be delivered and may become insane. Consulting specialists may so supplant the general practitioner that his type shall become extinct; but in the profession of nursing the good, all-around nurse is what is wanted now, and will be forever.

As a remedy for the present confusion, it might be thought possible to secure some coöperation among the different training-schools, such as has been secured in other cities; but that hope need not be entertained for Boston, for so jealously guarded are their doors, that not even the graduates and superintendents of other schools are allowed opportunity to study each other's methods of training. In other cities, both in this country and abroad, such opportunities are most hospitably afforded. In Boston, it would be considered most impudent even to suggest to any one training-school the possibility of its being improved by association with any others, and any appeal for a more general distribution of its peculiar advantages is met by the courteous announcement of its weekly lectures and monthly conferences, which by the liberality of the trustees are open to outsiders.

The means of improvement must, therefore, be

sought independently of present organizations. It would be easy, for instance, for the Obstetrical Society to inaugurate, or at least to matronize, a course of post-graduate instruction in obstetric nursing which should include a stiff course of lectures, recitations and examinations, with practice under approved instructors in the dispensary districts and in the homes where only very moderate wages could be afforded. The diploma granted to those who earned it would give a rating like that of the London Obstetrical Society. Were such a course of instruction offered, hundreds would apply. There would be an immediate supply of nurses for the poor, and for those who can pay at most only a few dollars for their care during confinement. The instructors in this post-graduate school, in return for their teaching, would have an abundance of assistance, and would be saved many hours of weary nursing service which they now endure.

In the same way, other societies might inaugurate special post-graduate courses of instruction in other departments of nursing. Thus nurses might be taught how to take care of infants, a department now most sadly neglected.

But better far than separate and independent post-graduate courses would be a central post-graduate school which would have general management. Such a school could do more for the advancement of the nursing profession, and consequently, for the advancement of the practice of medicine, than any agency within the realm of things possible and practicable.

Such a school would need no endowment. From its inception it would be more than self-supporting. Out of it would grow perfect systems for the registration and the distribution of nurses. In place of feeble guilds and graduate clubs would grow a large, strong association of all the members of the nursing profession. And finally, Boston might so regain her old-time preëminence as an educational centre for nurses.

One of the many advantages that would result from such a central post-graduate school would be that of uniformity in the matter of giving diplomas to nurses. The course of instruction would have to be lengthened, which by no means should be considered a disadvantage. Graduates of the present schools might then seek work as they do now, or they might take the different courses and examinations of the post-graduate school in the surety that, having obtained the advanced diploma, their services would be in greater demand.

This in time would naturally lessen the apparent value of the diploma now given by the different schools; but if it led, as well it might lead, to a uniform examination by the central licensing board, the greatest benefit would result.

Thus, in the special department of instruction under our present consideration, there is now no uniformity in the different diploma-giving schools, and we have no means of ascertaining what instruction has been given to the nurses who are engaged for our obstetric cases. For this we have only ourselves to blame, for if we instituted even examinations for nurses in this department, the different schools would at once try to conform their instruction in this branch in order that their graduates might with least difficulty obtain the advanced diploma.

As is true in every professional school where the diploma carries with it any certificate of fitness to practise, the diploma is open to suspicion if it be

granted solely by the instructors of that particular school. Thus, for instance, the possessor of such a diploma may be better versed in the different instructors' whims than in real knowledge.

If, then, we cannot at once arrange for post-graduate instruction for nurses, let us at least arrange for the examination of nurses, and so secure some sort of uniformity in their training.

THE GASTRIC AND RESPIRATORY SYMPTOMS CAUSED BY THE DUST OF CURLED HAIR.¹

BY ARTHUR P. CHADBOURNE, M.D.,

Physician to Out-Patients, Carney Hospital; Demonstrator of Experimental Pharmacology, Harvard Medical School.

CONSIDERING the great differences in the composition of the various kinds of "dust" that are known to cause so-called "dust-disease," it is somewhat surprising that it should have been possible to group almost all the resulting symptoms under the single disease called "fibroid phthisis," or "pneumokoniosis."² The list of industries that are recognized as being dangerous to the workmen on this account is already a long one, and a single addition to the number would be of little interest. The patient who is here to-night, however, has no evident signs of a "fibroid" change in the lungs, though his symptoms undoubtedly arose from continued exposure to dust in the factory where he has worked for many years.

Before giving the history of the present case, let us consider what this dust really is, and in what ways it would be likely to act in producing disease. Though there are hardly any two of the "dust-producing trades" in which the composition of the dust is exactly the same, yet in all the dust is alike made up of minute particles, so small as to float about for some time and be easily drawn in with the air breathed by the workmen. The action of these minute particles may be purely *mechanical*, and it is largely, if not entirely, from this mechanical irritation that so-called "fibroid phthisis" is commonly believed to arise. In the second place, the great differences in the *composition* of the different kinds of dust might well be expected to influence its *local action*, if nothing more. Among the substances that make up these minute particles are some that are known to have a marked action on the human organism as a whole; in others the effects are more local, or confined to one or more groups of organs; some are accumulative, others active poisons; while still others are probably inert, at least in the form in which they occur in the dust, and finally, quite a number are used as medicines. Plant and animal products, as well as inorganic matter, are among them.

Such substances may reach the larynx and respiratory tract, either by way of the nose and naso-pharynx, or directly through the mouth; but a part of the inhaled dust must be carried into the oesophagus, and in this way may enter the stomach. The portion of the foreign matter that can be absorbed, either changed or unchanged in chemical constitution by the secretions and tissues with which it may come in contact; and its characteristic general symptoms will then follow if the amount which thus enters the system is sufficiently great.

To return to the history of the present case, in which the action of the dust is certainly not that of a purely mechanical irritant.

J. D. came to the Carney Hospital (A. P. D.) in January, 1894. His family history was excellent. He had never been "sick in bed a day in his life that he could remember"; nor had he had any "lung trouble," except a few days' cough when "he had taken cold," and when working in the dust of the factory. On Sundays and holidays never coughed at all. Habits and personal history good.

For twenty years he has steadily worked in the same factory, with the exception of a few months when he was "train-hand" on a railroad, but this was thirteen years ago. In the factory, "curled hair" is prepared for mattresses, etc. Both horses' and pigs' hair is used, but only the latter is dyed; and it is when this dyed hair is used that he is troubled with his present symptoms. The pigs' hair is "disinfected" as soon as it is received at the factory, and is then thrown into large vats, which contain a mixture of logwood (*hæmatoxylin*) and copperas (iron sulphate, with copper sulphate as an impurity, and more or less sesquichloride of iron³). When thoroughly stained, the hair is removed and dried; it is then piled up ready to be put through a machine called a "separator." The "separator" pulls apart the tangled masses of hair, while a blast of air is at the same time forced through to remove the dirt, broken pieces of hair and other dust. This dust completely fills the air, and rapidly accumulates around and on the machine. The patient "feeds," that is, keeps the "separator" supplied with hair from the heap already mentioned, and has, therefore, been obliged to breathe the dust-filled air near that machine for almost twenty years.

He describes his symptoms somewhat as follows: When actually in the dust he always has more or less cough, and raises a "little thin, frothy spit, which is rather blue-colored"; but as soon as he stops work the cough stops also. For two or three weeks before I saw him he had what he called a cold, and was then raising more or less sputum all day and more at night. When working with the dyed hair the color was blue, but in the morning white and "lumpy." The specimen brought me was muco-purulent, white, and careful examination failed to show tubercle bacilli. The chief complaint, however, was of his "stomach," which had "hurt him in the same way ever since he had been in the factory, but was getting worse lately." When undyed hair was being prepared his "stomach was much better always." There was a sharp, burning pain, beginning just below the sternum, and going straight up to his "Adam's apple" (larynx) and his "mouth tasted bitter and like brass." There was pain in the epigastrium, which increased with pressure. Appetite fair. Bowels always regular, and dejections natural color. No vomiting; nausea occasional. These symptoms begin two or three hours after he has worked with the dyed material, and sometimes last a day or two after he has stopped using the dyed material. No marked loss of flesh.

On *examination*, the patient was thin, and, though poorly developed and hollow-chested, was not emaciated. Marked cyanosis and dyspnoea were absent. The tongue was thickly covered with a yellowish-brown fur. The chest showed nothing abnormal, ex-

¹ Read before the Section of Clinical Medicine, Pathology and Hygiene of the Suffolk District Medical Society, February 21, 1894.

² Dust which contains lead, arsenic, etc., of course an exception.

³ Lead, zinc and arsenic were tested for in the dust, but were not present.

cept slight signs of a localized bronchitis at the right base behind.

He was given ten drops of terebene for cough p. r. n., also told to take the white of a raw egg when he felt the burning pain coming on, and about ten minutes later to take ten grains of bicarbonate of soda. Maltine given as a tonic.

On his return about a week later, he reported (considerably to my surprise) that the "stomach trouble" had entirely stopped, and for two days he had not been obliged to take the medicine. The day previous he had worked with the dyed hair, but without the usual discomfort. The sputum, which he brought me, was: (1) Specimen raised in the morning before going to work, and after having been in the *dyed dust* the day before: it contained a few small fragments of dyed hair and unidentified foreign matter. No logwood fibres. There was a very slight reaction for copper, and a well-marked test for iron. (2) Specimen raised at noon after a half-day's exposure to the *dyed dust*: The sputum was frothy, mucous and strongly tinted with blue, while in it were many dark-blue specks. Microscopically, these blue fragments were evidently plant-fibres of some kind, and around each was a kind of halo of lighter blue; they were undoubtedly bits of logwood. The broken fragments of hair were surprisingly few; almost all were dyed, but the undyed hairs were most of them quite different in form from the stained specimens, and must have been horse-hair. Chemically, the copper and iron tests were much stronger than in the first specimen. (3) Specimen after a morning's work with undyed horse-hair: The sputum was very small in amount, frothy, thin and unstained. Microscopically, it showed a few unstained fragments of hair, similar to the unstained fragments of the second specimen, but no logwood fibres. The chemical tests for iron and copper were negative. No bacilli of tuberculosis could be found in any of the specimens. The examination of the dust from under the "separator" corresponded with that of the sputum; iron and copper, dyed bits of hair and unstained fragments, evidently from a different animal, bits of logwood and foreign matter being found. As already stated, zinc, arsenic and lead were absent in the dust.

Since he first came to the hospital I have seen the patient several times, and the gastric symptoms always return soon after exposure to the dyed-hair dust; but they have thus far always yielded to the treatment first prescribed. The signs in the lung finally disappeared, and when he was seen by Dr. F. C. Shattuck, who most kindly examined him for me a few weeks ago, nothing abnormal was detected in the chest.

Two points seem to me of special interest in this case: first, the absence of any signs of an abnormal condition either in the larynx or lungs after twenty years of almost daily exposure to this dense dust; second, the evident symptoms of marked irritation of the digestive mucous membrane, without a similar condition in that of the respiratory tract, though the latter would seem likely to be the most easily reached by the irritating particles. To what extent absorption has taken place in the present instance — if such has occurred at all — it is, I think, impossible to say.

To try to determine this question, and also to, if possible, show the probable condition of the lungs from exposure to this dust, I have kept some animals for several hours each day in a close cage, into which this dust is blown continuously. Judging from similar

experiments with coal-dust, it will be from sixty to ninety days before any pathological change is likely to occur.⁴

Clinical Department.

THE OPEN INCISION IN UNCOMPLICATED CASES OF HYDROCELE.

BY PAUL CLENDENIN, M.D., FORT BRADY, SAULT ST. MARIE, MICH.,
Captain and Assistant Surgeon, U. S. A.

I READ with a great deal of interest the paper by Dr. M. F. Gavin, and the discussion thereon, in your issue of March 1st. I cannot accept the doctor's dictum, "No simple, uncomplicated case of hydrocele ought to be treated other than by injection." And I must take exception to his statement, "The open incision, with or without excision of the sac, means the administration of an anæsthetic [general, I suppose he means], detention in bed for a varying period from one week to four, while to undergo an operation has considerable effect on the minds of most of our patients."

Permit me to refer to my own experience, limited though it be, to show the simplicity of the open incision in uncomplicated cases.

CASE I. H. K., soldier, German, thirty-two years old, of fine physique and in vigorous health. This man presented himself at the hospital November 8, 1891, expressing the desire that I should look at his scrotum, and, if possible, relieve his discomfort. Inspection showed a swelling of five and a half inches in length by about three and a half inches in greatest width, situated in the right compartment of the scrotum. It was easily determined to be a simple hydrocele. The man stated that he had first noticed the swelling six or eight months previously, but had paid no attention to it until the tumor became an annoyance on account of its size. It was at no time painful. I had examined this man as a recruit in November, 1890, and I know the tumor did not then exist. Despite the fact that the hydrocele was of comparatively recent origin, and that the wall of the sac presumably was not thickened to any extent — I say *presumably* on account of its recent growth, for the tumor was so tense that it was impossible to determine positively the amount of thickening — and notwithstanding it barely exceeded the limit in size usually laid down for cases suitable for operation, I decided to perform Volkman's operation rather than trust to paracentesis and injection of some irritating fluid, which, to me, is a most unsurgical procedure.

Having done a Volkman's operation three years before, and been rewarded by seeing recovery without the appearance of a single drop of pus, I made every effort to obtain the repetition of so desirable a result.

⁴ On March 16th one of the rabbits referred to above was found dead in its cage. During about five hours (average) each day it had been in a closed cage, to which a steady current of air filled with dust from under the separator was supplied and kept in motion by a forced blast. For two days before death the animal had not seemed well, and had, therefore, not been placed in the dust cage. There had been no cough and no sneezing, except during the first week; and until March 16th the appetite was good. Up to March 12th (the twenty-sixth day) there had been a loss of one-quarter of the original body-weight. Death occurred on the thirtieth day. On post-mortem examination, twenty-four hours later, nothing abnormal was found, except that the mucous lining of the stomach was throughout thickly studded with small spots and larger patches of dark brown or black, which, microscopically, proved to be not a post-mortem change, but a *hæmorrhagic gastritis*. A pathological change in the lungs was not to be expected after so short a time of exposure to the dust; and it is as yet too soon to determine the results of a sufficiently long exposure under the same conditions.

After a bath, the man's abdomen, pubes, scrotum, perineum and thighs were shaved from the umbilicus to the mid-thigh, the parts then scrubbed with soap and water, and afterwards with ether, and finally laved with a solution of bichloride of mercury (1-1000). Equal care was bestowed on the toilet of my hands. The instruments were boiled, and afterwards immersed in a solution of carbolic acid (1-20). A length of rubber tubing (also treated to a bath in the carbolic solution) was wound tightly around the base of the penis and scrotum and secured. Sixty minims of a four-per-cent. solution of cocaine hydrochlorate were injected along the line of the intended incision, resulting in complete abolition of painful sensation in about eight minutes. An incision of about two and a half inches was then made through the integument and down to the sac. Loops of silk were passed through the sac wall at the end of the incision and tied, as my former experience had taught me that the retraction of the tissues due to the subsequent irritation of the

carried to the lowest part of the cavity and secured by a safety-pin after slipping it through a hole in a piece of rubber protective-tissue long enough to cover the wound with a small margin. This was covered with a layer of hydroscopic gauze moistened with bichloride solution (1-3000), which in turn was covered with dry gauze, and over all a double layer of protective extending (with a wide margin) over the entire dressing. The dressing was secured by a firm bandage, so arranged as to apply considerable pressure and support the parts. As each layer of the dressing was applied, a hole was cut in it and the penis drawn through. The man was directed to turn on his side in urinating, and cautioned by no means to allow any urine to soil the dressings. The bandage was arranged to avoid as much as possible any soiling of the dressing by the fecal discharges, and an inspection of the dressing after each evacuation ordered made by the nurse.

The man was permitted to sit up as soon as he felt so inclined, which was on the third day, the only re-

CASE I. Cremaster contracted.

CASE I. Cremaster relaxed.

interior of the sac caused it to be difficult to secure nice coaptation of integument and serous membrane in the subsequent suturing. The sac was then incised to a trifle less extent than was the integument; the hydrocele fluid was evacuated; and the cavity of the sac swabbed with a five-per-cent. solution of carbolic acid in glycerine, as recommended by Gerster. The edges of the parietal layer of the *tunica vaginalis testis* were then united to the edges of the integument by a continuous suture of catgut, very much as a tailor makes a button-hole. In making this suture, it was found that the skin and the sac wall had both retracted more than the cellular tissue lying between them. This was so because of the cocaine injected—such, at least, is my opinion, for it was gelatinous and clear, and had the appearance of infiltration of fluid; furthermore, there was no such appearance in my former case, in which general anaesthesia was obtained by ether. This redundant tissue was removed by the scissors before suturing. The sac was washed out with a bichloride solution (1-3000), and the surrounding parts bathed in the same. A second swabbing of the interior of the sac with the carbolic solution was done, and the wound was dressed. A drainage-tube was

stricture being to refrain from walking around. The dressing was not disturbed until the bandage became loose, which occurred on the ninth day, when we were rewarded by the sight of a clean, dry wound, perfectly odorless except for the odor of the rubber protective. The scrotum was considerably swollen, and had a doughy feel. The sutures had disappeared, and the drainage-tube had been pushed out and was in the dressings. The incision was a deep sulcus in the side of the scrotum, by parting the lips of which a pink line could be seen apparently perfectly healed. The dressing had been stained by the serum, and had a brownish color, but there was no evidence of pus. There had been no pain, no rise of temperature. Mindful of the caution of Knester, as quoted by Senn in his article on "Hydrocele" in Buck's Hand-book, that failure attends this operation at times because of the too early suspension of antiseptic precautions, a dressing similar to the first one was applied after a thorough washing of the part with the 1-3000 bichloride solution, discarding the first layer of protective.

On the fourteenth day the dressings became disarranged on account of the active movements of the

man, and the wound was again inspected. The gauze was slightly stained, and at the lower part of the cut corresponding to the site of the drainage-tube were a few granulations. These were touched lightly with nitrate of silver, a little calomel dusted in the sulcus, and a dry dressing applied and held in place by a suspensory bandage. The man was fit for duty at this time, but was kept under observation until the twentieth day, and engaged in such occupations as are suitable for a convalescent. When the man returned to duty the scrotum and contents seemed normal in size. No cicatrix was visible, nothing but a deep sulcus (see photograph). The scrotal wall was adherent at one point; apparently the sac was obliterated.

CASE II. The case referred to as operated on three years previous is that of a young man of twenty, a railroad brakeman, on whom I operated at Laredo, Tex. In this case the tumor was five inches in length and of about a year's growth, situated also on the right side. I operated precisely as in the case just reported, except that ether was used for anæsthesia, and the dressing was the same, except that iodoform was used. The dressings were removed the eighth day, disclosing a dry, clean cicatrix. The young man insisted on going to his home in Corpus Christi, Tex., as soon as the second dressing was applied, and went back to work on the road the next week. Either of these men would have been at work a week after the operation had they been professional or business men.

It seems to me that open incision is the only operation for simple hydrocele of any size. The operation is not formidable with cocaine anæsthesia. My soldier watched the operation with interest, commenting on the various steps in "asides" to the nurse, and seemed quite cheerful.

I have characterized the practice of paracentesis and injection with an irritating fluid as unsurgical. I do not draw on any extended experience for this opinion, for I have treated but one case by this means. A comrade of my brakeman came to me a short time after the operation with the request that I operate in like manner on him. He exhibited a hydrocele about the size of a large hen's egg, from which I removed the fluid, having thrown a few drops of cocaine solution into the site of my puncture, and then injected the sac with twenty minims of pure carbolic acid, as recommended by Levis, at the same time promising to operate as he desired in the event of a recurrence. I have never seen the man since. I heard indirectly that he was "all right," by which I felt assured that none of the accidents which sometimes follow injection — as suppuration of the sac, gangrene of the scrotum, or even of the testicle — had occurred, but was left in ignorance of the success or failure of the purpose of the operation.

It is on general principles that I object to the injection of an irritating fluid into the hydrocele sac. It seems to me unsurgical and unscientific to set up an inflammation in a closed sac, which at once proceeds beyond your control, has no drainage, and may do serious damage to important structures. Agnew states that he has had but one failure in a number of years with the injection of tincture of iodine. Other surgeons have not had such brilliant success. According to Senn, in the article above referred to, nearly as high as fifty per cent. of failures have been reported as the result of this operation. Nineteen cases were reported by Bardeleben showing sixty-five per cent.

successful; and there are cases on record of serious results, involving even loss of life, following the injection of the tincture of iodine. The use of carbolic acid seems to promise better results, but I am not able to find any statistics concerning them.

Injection, then, does not appear to be either safe or sure; still it is spoken of by Agnew, Wyeth and others as the conservative method, to be tried in the majority of cases before attempting the more formidable procedure of Volkmann. If we had the power to set up just a sufficiency of inflammation to obliterate the sac, and not enough to do any damage to the structures involved, injection would be the ideal operation; but, unfortunately, the most of us have no such power. To be sure, the interior of the sac is irritated by swabbing with the carbolic-acid solution in the open treatment; but it is quite another matter to irritate a tissue after drainage is established.

The operation of Volkmann appears to me to be the safest and surest. With cocaine anæsthesia it is not formidable, and with attention to antiseptic precautions it ought not to be serious. The man is incapacitated for duty but a few days, not much longer than the rest recommended after injection. And with attention to the irritation of the interior of the sac by the carbolic acid, the result should be fairly sure, the failure being frequently, if not usually, due to the non-obliteration of the sac on account of the "too antiseptic" healing of the wound.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

J. T. BOWEN, M.D., SECRETARY.

REGULAR meeting, Monday, February 12, 1894, the President, DR. C. F. FOLSOM, in the chair.

DR. A. T. CABOT reported a case, illustrative of THE CHANGE OF A BENIGNANT TUMOR INTO A SCIRRHOUS CANCER IN THE BREAST.

The patient was a lady fifty-four years of age, who had had more or less trouble in her breast for over twenty years, this having first appeared at the time that she was nursing her first child, now twenty-six years of age. For ten years she had noticed a lump in the outer segment of the right breast which during that time had not materially altered in size.

She was seen by Dr. Cabot in February, 1893. This little mass then was about the size of a large English walnut. It was movable, and seemingly not attached, either below or to the skin. She had noticed that this lump sometimes increased and became painful at the times of her monthly sickness, but then resumed its usual condition.

Dr. Cabot saw it again in July, when it seemed possibly a little larger than at the previous examination. The skin over it showed a little irregularity of surface, the irregularity seeming to be caused by a network of fluid spaces close under the outer layer of the skin. At no time could anything be felt in the axilla.

The patient was seen again in December, she having in the meantime had some electrical treatment, in the hopes of dissipating the lump. The condition of the skin was unchanged, and it was deemed wise to

remove the mass, not because it seemed like a cancer, but in order to leave no chance of neglecting a serious thing.

The growth was removed, with considerable tissue on both sides of it, and on section, it was found to present the characteristic appearance of a scirrhus cancer. At once the rest of the breast and the skin lying over it, and all of the axillary contents, together with the loose, connective tissue lying between the breast and the axilla, were thoroughly removed.

Dr. Whitney, who made the microscopical examination of the specimen, reported the nodule to be a scirrhus cancer, and after a careful search through the glands in the axilla, could find none in which any cancerous change had commenced. The dimpling of the skin seemed to be due to the drawing of little fibres, running from the growth to the under surface of the skin at one or two points.

The case was interesting, as showing how a benignant tumor may insidiously take on a malignant character, and illustrated the importance of keeping such a tumor under observation and of removing it early, if any appearance about it suggested a suspicion of its character.

The wound healed by first intention. Care was taken to make the section of the growth with a knife which was not used further in the operation; and the hands were carefully washed after this examination was made, before proceeding with the operation, in order to obviate the danger of any of the cancerous cells being transferred to the healthy parts. It seemed like a remarkably favorable case for a cure.

Dr. W. T. COUNCILMAN showed specimens of

PERITONITIS DUE TO EMBOLISM OF THE MESENTERIC ARTERY.¹

DR. A. T. CABOT said that he had urged at a recent meeting of the Massachusetts Medical Society the importance of recognizing embolism of the mesenteric vessels as an occasional cause of obstruction of the bowels, and that the cases shown by Professor Councilman were interesting as bearing out this view. He said that he had seen cases in which a diagnosis of volvulus was made and in which he had no doubt this embolism existed.

DR. M. H. RICHARDSON: I think with Dr. Cabot that Dr. Councilman's remarks upon this possible cause of peritonitis are of great interest. That a general fatal peritonitis may be due to an interference with the intestinal circulation which is beyond surgical relief, is a fact of the greatest importance. I have considered the question of interference in such cases several times this last year. In the one of which Dr. Cabot speaks, volvulus was thought to be present. I made the autopsy, and sent the abdominal organs to the hospital. Dr. Fitz was unable to demonstrate the precise lesion. Dr. Cabot will remember two cases at the hospital of supposed general peritonitis following fractures of the thigh. There was some question of thrombosis or fat embolism at that time.² In the first case fat embolism was found at the autopsy; the second case was not examined post-mortem. Not long ago, in consultation with Dr. Shattuck, the question was considered of operating in the following case of apparent general peritonitis and obstruction following typhoid fever. It seemed very probable that there

was a portal thrombosis or an embolism — something which no operation could relieve.

Mrs. H., aged twenty-three, was convalescing in the fourth week of typhoid fever. The attack, mild throughout, was uneventful till thirty-six hours before my examination, made at 2 A. M., October 22, 1893. Eight days before she had had pain in both legs, for which a hypodermic injection of morphine had been given. At one o'clock, Friday, she was seized with severe epigastric pain relieved by half a grain of morphine. This was followed in twelve hours by vomiting, which soon became stercoraceous. Her bowels moved freely Saturday night from a glycerine enema. Her pulse Sunday morning was 132, the temperature 99°. The facies was peritoneal and the general condition bad. There was some tenderness above and to the left of the umbilicus, where distended coils of intestine could be felt distinctly. There was no general distention, though the abdomen was rather full. The patient's condition was deemed hopeless, and no operation was advised. The diagnosis by exclusion indicated portal thrombosis as the probable lesion, though the possibility of some pancreatic affection was considered. Death took place in forty-eight hours. The autopsy by Dr. Whitney was unsatisfactory on account of the interference with the pathological appearances caused by the undertaker's fluid. There was no lesion of the intestinal tube, however, nor was anything found incompatible with the diagnosis of portal thrombosis.

In this case, as in the one referred to by Dr. Cabot, and in a fatal³ appendicitis the most marked physical sign was the distended coil of small intestine. In such cases the segment of bowel is darkly congested, and heavy with blood and fluid. The sensation of tension and resistance through the abdominal wall is characteristic of a tightly distended coil, but no inference can be drawn as to its exact cause without careful consideration of the history and accompanying physical signs. The clinical features of cases of this kind are of the greatest interest to me; a satisfactory pathological explanation of them that will enable us to avoid operating in hopeless cases will be extremely valuable.

I have no doubt that we have erred in our diagnosis even at the operations for fatal cases of apparent peritonitis, not only because it is impossible at times to tell the exact pathological lesion, but because no autopsy is allowed. All who operate in acute abdominal conditions must be able to recall such cases.

I was very much interested in what Dr. Councilman said about the colon bacillus and its means of invading the tissues. I have had cultures taken in all abdominal operations in the last six or eight months. The fact that many of the alimentary micro-organisms will not grow in the ordinary media is very interesting, but it does not militate against the important clinical observation that, as a rule, if the cultures fail the patients get well; if the colon bacillus from a general exudate does grow on the culture media, the patient dies. This has been the invariable rule since I have made cultures, but the number of observations is still too small for any sweeping statements.

STRICTURE OF THE URETHRA, WITH SPECIMEN.

DR. RICHARDSON: This specimen is a firm, fibrous stricture of the urethra, dilated just in front of the

¹ See page 410 of the Journal.

² See paper by W. F. Whitney, Boston Medical and Surgical Journal, February 18, 1892.

³ Case of G. W. S., in Boston Medical and Surgical Journal, January 19, 1893.

bulb. The patient, a man of about thirty, received some years ago a blow in the perineum which resulted in a stricture that was almost impervious. The urine escaped constantly by drops. The bladder was enormously distended. Nothing could be introduced. By perineal section the fibrous mass was easily exposed. Above the constriction the urethra was much dilated; below, though healthy, it was flattened and contracted from practical disease. By transverse cuts above and below, the whole mass was removed. The ends of healthy urethra were brought together easily upon a No. 18 English sound, and fixed in satisfactory approximation by means of interrupted silk sutures. The deep union was immediate. The urethra was at once restored to its normal function. The patient has gained thirty pounds, and is in perfect health.

SPECIMEN OF APPENDIX.

DR. J. W. ELLIOT: I removed this appendix about ten days ago from a boy of thirteen. He never had an attack before. The attack began on Thursday, and his bowels were moved with oil and he was better on Friday. On Saturday more pain, and on Sunday his bowels moved again. On Tuesday I saw him and operated at once. He had a temperature of 101°, pulse of 90. The abdomen was not tympanitic, but there was a certain cakiness, on the right side, which I thought was omentum and which turned out to be omentum. The interesting thing about this specimen is that although the attack was acute, the appendix looks like a chronic appendicitis. The whole appendix is thickened and stiff. The acute part was due to the sloughing of the tip, which is opened and perforated; the omentum was wound round the appendix and saved the boy's life. There was about a teaspoonful of pus near the gangrenous tip with omentum round it. The boy made a good recovery.

DR. W. T. COUNCILMAN: I should like to say that a short while ago I made an autopsy in which there was congenital absence of the appendix. I made the dissection with the greatest ease, and no traces of an appendix could be found either on the outside or in the inside, but in the small intestine just above the valve there was a small diverticulum extending into the tissue for about one-half to one inch, which I do not think was at all analogous with the appendix. But it was interesting to find this diverticulum at the end of the small intestine with entire absence of an appendix.

DR. H. L. BURRELL read a paper on

THE AFTER-TREATMENT OF APPENDICITIS.⁴

DR. G. W. GAY: I was interested to hear Dr. Burrell describe his method of treating the stump of the appendix. In some cases, as we all know, that is the only thing we can do; the appendix is so rotten, that there is no taking sutures of any sort in the appendix itself, and in some cases, of course, nature does all that herself. The ideal way of treating an appendix, where you can, is to dissect off the outside covering, tie the appendix itself with catgut, bring the cover up over, and sew with a fine catgut suture. I most heartily agree with Dr. Burrell, when he says that he does not use silk about the appendix. I never leave silk in the peritoneal cavity if I have any suspicion of suppuration afterwards, because it often acts as a foreign body and keeps up a sinus for an indefinite length of time. It is not easy to open a wound and find a suture buried

at the bottom; it may be covered with granulations. I have in mind two cases of removal of the Fallopian tubes in which the tubes were tied off with silk, and the sinuses have never closed. Theoretically, the proper way is to close the stump of the appendix in a way to bring other tissues together than the mucous tissues. If you cannot do that, I like to use the gauze drainage. I do not like rubber tubes for drainage. The wound shrinks in twenty-four hours so that all the drainage you get is what is about the tubes, and it is not so thorough and efficient as it is to pack the wound with sterilized gauze, leaving that in three to five or six days. You probably get in that way as good drainage as it is possible to get in these cases, provided it is not a large pus cavity, when it is simply a case of putting in drainage-tubes and washing out as you would any abscess.

In regard to the use of saline cathartics or cathartics of any sort, I feel very much indebted to the gentlemen who have called me in consultation for one thing, and that is, I have learned the effects of cathartics. Almost all the cases I have been called to have had cathartics, and I have had a good chance to study their effects. In many cases they have been given where I should not dare to use them. In some cases they seem to do good, in some cases harm. In the case of acute sharp appendicitis I should not dare to give cathartics. In the case of moderate appendicitis I think it does not make so much difference if you give a saline or a dose of castor oil. I have seen a good many cases where they have received those remedies, and at the end of four or five days they have turned the corner and got well. In a severe case I think it is pretty well agreed that it is better not to give laxatives at all. After the operation the question comes, When shall we give cathartics? I do not like to give a cathartic under three or four days. I have the fear that by starting up peristalsis I may rupture the catgut ligature or perhaps produce a leak through the stump of the appendix, which perhaps drainage will not control. That is an objection which may perhaps be theoretical. As soon as I feel reasonably sure of the stump of the appendix, so that if any contents do come out they can be readily taken care of, I believe most thoroughly in salines given in small doses and frequently repeated. Vomiting is no bar to giving saline cathartics. I think I have seen vomiting stopped in peritonitis in other operations about the pelvis by giving saline cathartics; and my rule in threatening peritonitis is to give them in teaspoonful doses every hour, vomiting or no vomiting, until the bowels are evacuated.

In regard to opiates, I never have let my patients suffer very much for the want of an opiate. I think that pain has a good deal of depressing action upon the patient's strength, and I think probably the opium does more good than harm. One of the best tonics or stimulants after these operations, as after all peritoneal operations, is strychnine. I think it is better even than the alcoholics or better than anything else I know.

In regard to the time of removing the drainage, as Dr. Burrell says, it has got to be decided in every case, and you have got to go by your judgment. If there is going to be any walling off of the wound, it takes place within two or three days generally. After that you may begin to remove the gauze and, so far as I know, I have never seen any symptoms arise, which showed that the gauze was removed too soon, and the peritoneal cavity reinfected. Rubber-dam in these

⁴ See page 433 of the Journal.

cases I have not used much for drainage. I have used it in breasts, and I think it is pretty good there. I believe where there is no pus, in closing the peritoneal cavity, as Dr. Burrell says, a line of sutures for the peritoneum, another for the muscles and transversalis fascia, and another for the muscles and skin. I believe that the more attention wounds get the better. Even if you close the abdominal cavity up tight, I always like to see it at the end of three days, and I never let a wound go over five days without looking at it. If there is to be trouble, I think you will find it on the third day, as a rule; from the third to the fifth day have been the critical times in my experience. I believe in seeing the wound pretty often, and then you can take steps to correct mistakes or unfortunate occurrences. The other points that Dr. Burrell brings up are so well founded in my opinion, that I have nothing to say in relation to them.

DR. M. H. RICHARDSON: This subject should be divided for discussion into two or three distinct classes:

First, the cases in which the comparatively normal appendix is removed in the period of abeyance, when it is possible to close the abdominal cavity at once. In these cases, as far as I have observed, it makes no difference whether we use catgut or silk for tying the appendix or whether we cover the stump with peritoneum or not; whether we simply cut off the appendix and sear it with the actual cautery; whether we touch the pedicle with peroxide of hydrogen or corrosive sublimate or whether we drop it back untouched. These cases all get well as far as I have observed in this community. Not that in so safe an operation there is no danger; the accidents inherent even to the simplest procedures make a probable mortality in this of two or three per cent. The only occasion for drainage in this class is when there is a septic exudation about the appendix. Under such circumstances a slender gauze wick should be used, to be withdrawn in forty-eight hours.

Secondly, the gangrenous appendices with more or less extensive extravasations. In these cases the material used and the manner of applying the ligatures are indifferent so long as two things are accomplished—the restraining of further extravasations and the controlling of hæmorrhage. To spend valuable time in attempting to cover in the stump of the gangrenous appendix—inflamed, swollen, and friable, like those I have just exhibited—is often impossible, is always unnecessary and unwise. The only object for such a procedure is to make immediate closure and first intention possible; for extravasations are effectually restrained by the ligature, or if that gives way, they are provided for by the gauze or tube drainage.

I do not believe in the use of salines before operation, because the first symptoms in most severe cases of appendicitis are caused by fecal extravasation, often aggravated by cathartics. The opening in the appendix and into the cæcum may be as large as the opening of a bullet wound. I have seen thin fecal matter escaping from the appendix in several instances. I have not the slightest doubt, therefore, that salines have killed a good many people who, perhaps, would otherwise not have died. After operation, when the appendix has been securely tied, or when extravasation has been provided for by drainage, salines fulfil a very useful purpose in exciting abundant liquid discharges and in eliminating the toxic products of germ growth. Yet I cannot help feeling that perhaps too much reli-

ance is placed upon their use; that in a general peritonitis, with the intestines paralyzed, the abdomen distended, and the patient constantly vomiting, salines do no good whatever. They may even do harm by adding to the patient's burdens. I have never yet seen a case recover under these conditions, with any method of treatment.

With regard to intestinal drainage by enterotomy, I have seen this done once with marked success by Dr. Warren. The peritonitis had been going on for some time, and was not of the fulminating variety. Recently, in another case of general septic infection, I opened the cæcum after having drained in the median line for appendicitis with extravasation. The adjacent segments of the large intestine emptied themselves through the lumbar opening without any permanent benefit. The patient soon succumbed.

Third, abscesses in which the general peritoneal cavity is not infected generally do well, whatever method of drainage may have been used, provided it is effectual. I prefer the use of both tube and gauze, the latter in slender wicks. Gauze tightly packed often acts as a plug and prevents the escape of pus. I have used many methods of irrigation in circumscribed abscesses. None is more effectual than thorough flushing with boiled water. Recently I have tried peroxide of hydrogen in these cases, followed by that of the normal salt solution, as recommended by Dr. Morris, of New York. I have not observed any improvement in results by this method. On the other hand, I believe that there is a distinct disadvantage in the use of irrigation in local infections which have not become general—in which the adhesions are broken down, but in which there has been as yet no extensive soiling of intestinal coils. The use of warm water, under such circumstances, is hazardous, because it may spread to distant parts colonies of bacteria which by the dry-gauze method would be confined to the immediate vicinity of the drainage-tube.

In many cases of circumscribed abscess drainage has been followed by a fistula. This appears usually some days after operation, and often results from the sloughing of the stump. In these cases, with one exception, the fistula has closed spontaneously. In two instances occurring in the practice of others I have closed the fistula by resecting the intestine. In two cases malignant disease of the cæcum eventually complicated, if they did not cause, the fistula.

I have never seen any bad results from the presence of germs in a well-drained wound.

Too much gauze sometimes causes obstruction, either by direct pressure or by keeping the intestines in a faulty position until adhesions form and cause acute obstruction. Such a case I have had in the last four weeks. By opening the wound and separating the recent adhesions the patient was permanently cured. I am afraid of iodoform freely used. Except in very rare instances I use only sterile gauze.

Care must be taken not to drain a cavity too long. A permanent fistula may be formed which will close only very slowly.

I cannot believe that it is justifiable always to remove the appendix. In circumscribed peritonitis separation of the adhesions adds enormously to the dangers of general peritonitis. I cannot understand how it can be regarded in any other light. Cases of abscess with localized peritonitis get well almost invariably; as large a percentage recover as in the oper-

ation for recurrent appendicitis. I know of one or two cases in which there have been subsequent attacks; in these the first opening was probably near the tip of the appendix, another fecal stone near the base causing the second attack. Nevertheless I do not believe that in many cases there is any recurrence of the trouble, even if the appendix is not taken out.

The reopening of the wound for any cause seems a grave sequel. I dislike very much indeed, once having operated, to go in again, for the reason that the peritoneum is shut off by adhesions so recent and delicate that you cannot avoid frequently infecting with your finger the peritoneal cavity. Perhaps this danger is not so great as it seems. When I have been obliged to reopen the wound and explore extensively, no untoward results have followed.

I have closed the wound only in the recurring cases, or in those operations in which the appendix seemed but slightly affected. I use the same method which I learned from Dr. Homans, that of applying but one row of interrupted stitches. For a short time this year we united the abdominal wall by layers. There seemed no advantage in this method, and it was soon abandoned. I do not think that hernia has followed any oftener in my abdominal cases than in those of most surgeons. In my opinion a line of stitches in the peritoneum is of little importance, and adds no strength. If you are going to bring together by a separate line of sutures the strongest layer in the abdominal wall, you ought to put a row in the external oblique.

I have had practically about as good results in those cases in which I have left the patient in the hands of the general practitioner as at the hospital where they have had the care of experienced men. Certain cases will die wherever they may be or whatever the treatment. In a small percentage of patients the result will be directly affected by the knowledge and skill of the attendant. On the whole, however, the results are about the same in one place as in another, by one method of treatment as by another. A series of three cases last summer shows that some are essentially, necessarily fatal. All three cases died. The trouble was not in the way the tube was put in, or the way the case was treated afterwards, but in the nature of the case; in every one there was general peritonitis. In one the colon bacillus was found, and in all a fatal termination was unavoidable. I do not believe that these cases could have been saved by any method of treatment that is known at the present time.

I would not be understood as saying that the after-treatment makes no difference, however. In my belief and experience it does make some. The result depends more upon causes beyond our reach than it does upon any special method of treatment.

DR. CABOT said that while there was no doubt that the patients did very well when the appendix was simply tied and cut off, still he preferred the method of stripping back a cuff of the serous coat, then tying the mucous and submucous coats with catgut, and after cutting off the appendix, bringing the serous coat together over the stump with fine silk sutures.

Among the possible causes for persistent vomiting after the operation, he would include iodoform-poisoning, which he thought was sometimes overlooked.

In regard to the closure of the wound, he said that he always used a single line of sutures, including the peritoneum, both deep and superficial fascia and the skin. He had noticed that in some cases while he was

at work, if the patient coughed, the wound was drawn firmly together instead of being separated by the action of the muscles. He thought that this occurred when the incision was carried just through the edge of the rectus sheath, having the tendinous linea semilunaris just outside of it. He always tried, therefore, to make his incision at this point.

DR. ELLIOT: I would say, in regard to the material used to ligature the stump, that I have always put silk in the abdominal cavity in septic cases and every other case, and never had any sinuses or fistulas connected with the silk. I do not believe it makes the slightest difference what material you put in. I think probably the old sinuses from salpingitis and tubes are due to part of the tube being left or part of the thickened tissue left. If the silk ligatures are sterilized, I do not believe they often make trouble. Having done several hundred cases of laparotomy, and having left silk in all of them, I think I should have seen trouble if silk was objectionable.

I agree with Dr. Richardson that it does not make much difference which way you treat the stump. If I had time enough, I should do as Dr. Burrell suggests.

So far as the after-treatment of the wound is concerned, I have some rather decided ideas of my own, and one is I almost never wash out an appendicitis wound. I am very much afraid of washing into the peritoneal cavity. I suck and swab it out. I think if you have a suppurating wound under the fascia, where pus is forming rapidly, you need a drainage-tube, because the fascia closes so tightly on the gauze that it leaves a very small opening indeed. If the gauze were changed often enough, it would counteract that pulling together of the fascia; but you hardly want to take the gauze out two or three times a day and put it back again.

DR. BURRELL: I differ entirely from Dr. Richardson in regard to the classes of cases. Up to last June I felt exactly the way he does in regard to this subject, that there were a certain number of cases going to die any way and a certain number of cases going to get well. I started in on my service last summer with the intention of investigating and seeing if there was not some possibility of saving those cases which are classed as fatal, simply from the fact that they have general peritonitis; and I satisfied myself, at least, that I could save a certain number of them.

I can recall at this moment four cases of distinct general peritonitis, not of the fulminating type, but where the abdomen was tympanitic, and where there were chills, yet these patients got well by care in their after-treatment.

DR. RICHARDSON: I would not for a moment be understood as maintaining that these cases of general peritonitis ought to be left to die unrelieved. Far from it. I have found at times a much more favorable condition of things than I had expected. Indeed, so completely may we be misled by the general appearance, the local conditions, and the constitutional disturbance, that all cases, unless actually dying, should be explored. Unfortunately the cases in which we are deceived are very rare. Only those should be described as general peritonitis in which by bacteriological examination the presence of micro-organisms is demonstrated in the *general exudate*, although, as Dr. Councilman remarks, some forms of bacteria doubtless fail to grow on the ordinary culture media. My experience may have been unfortunate, but in no case has recovery followed

a general bacterial infection, as shown by cultures from the general exudate. Cultures from the appendix alone are of no value whatever in deciding the question of a general infection. Practically, all appendices contain either pure colonies of the colon bacillus or a mixed culture, as shown by Mr. Darling in examination of my cases. Unless these micro-organisms have escaped into the general peritoneal cavity, there can be no general infection, and results following operations upon a supposed general peritonitis are of no value.

I have closed the stump as Dr. Burrell has suggested in every case in which the appendix was not gangrenous or infiltrated.

DR. BURRELL: I simply wish to place on record, Mr. President, that cultures were taken in all of these cases of general peritonitis, so that we know that the colon bacillus was present.

DR. J. G. MUMFORD: When the abdominal wound has been closed over an amputated appendix stump, the treatment is the simplest imaginable. I have never seen harm come from getting the patient onto a plain, regular diet by the sixth day, moving the bowels by an enema on the third day and giving a mild laxative each day subsequently. Even those cases in which a large incision has been made, and the wound filled with gauze-wicking and drainage-tubes may be conducted by common-sense rules.

The more I see of these cases the less I am inclined to feel that immediate movement of the bowels is essential. In perhaps the first fifty cases which came under my care I tried the use of cathartics — salines — as soon as possible after the operation. During the past year and more I have become much less eager to encourage peristalsis early. The patient's bowels are usually not loaded, though the rectum is often full. If there has been vomiting, the small intestine usually contains nothing but gas. The intestinal drainage is well accomplished through the artificial opening. It must be remembered, too, that this wound is an unusually painful one during the first day or two.

For these reasons I always order a large hypodermic of morphia to be given before the patient's recovery from ether, and except for washing out the rectum, direct that the bowels remain undisturbed for thirty-six or forty-eight hours. I then begin on cathartics, and of these I eschew salines. I was led to this first from finding the frequent impossibility of such treatment in children; I substituted for salts minute and frequently repeated doses of calomel. One-tenth of a grain repeated at fifteen-minute intervals will very often move the bowels before a whole grain has been thus given. Patients take this readily, the stomach is not disturbed, and nausea is apparently thus frequently checked. When the bowels have once been started they may be kept open by a mild laxative given every day.

As to the diet, to give nothing by the mouth the first sixteen hours, and then, beginning with liquids, to gradually work up to a full diet on the fifth day, is a good safe rule, if the case goes well. Stimulants should be given freely by rectum or hypodermically during the first two days. I prefer large enemata of the normal salt solution, or four ounces of black coffee combined with strychnia, given three or four times during the first twenty-four hours.

In regard to the care of the wound there is little I can add. The main point is to keep the dressings

clean and the tubes clear during the first two days especially. The outer layers of the dressing should be changed once or twice daily and the tubes very gently syringed out with boiled water. If there is much pain and distention, I usually order a large creolin pad to cover the whole belly, and change it every three hours. This often gives the patient a surprising degree of comfort.

I think we are inclined to pull out the deep gauze drains too soon and to leave in the tubes too long. The gauze wicks may usually be left in four or five days, and pulled out as they loosen. There is always some suppuration behind them. The new wicks should be very lightly placed. At the end of the week, if the case does well, we may begin to shorten the tubes. I seldom see occasion to leave them in longer than three weeks.

MASSACHUSETTS MEDICAL SOCIETY.
SUFFOLK DISTRICT.
SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.

HENRY JACKSON, M.D., SECRETARY.

REGULAR meeting, Wednesday, February 21, 1894,
DR. FREDERICK C. SHATTUCK in the chair.

THE PRODUCTION OF VACCINE VIRUS.¹

DR. D. D. GILBERT, of Dorchester, gave the report of a committee appointed by the Norfolk District Medical Society to investigate the production of vaccine virus.

After the reading of this report at the Norfolk District Society a motion was made that a committee be appointed to urge upon the legislature the establishment of a State institution for the propagation and supply of vaccine stock; that since vaccination is made compulsory by the law of the State it seems incumbent upon the State to provide for its inhabitants as pure and efficient vaccine stock as science can produce. That vote was passed, and a committee was appointed. That committee was instructed to ask the co-operation of the Suffolk District Society in bringing the matter before the legislature, and I suppose to your knowledge of that fact I am indebted for the privilege of reading this report to you to-night.

DR. S. W. ABBOTT: My interest in this subject is not merely a recent one, but dates back thirty years or more. I think it is not generally known among the profession that animals were vaccinated so long ago; but a considerable quantity of the lymph used in the army from 1861 to 1865 was obtained from cows. My preceptors, Drs. Benjamin Cutter & Son, of Woburn, took a very lively and personal interest in it at that time. The report upon that subject is to be had in the reports of the United States army of that period by Surgeon Milhau.² The method has been criticised from this fact, that some of the animals were vaccinated upon the principle of retro-vaccination, that is, by vaccinating a cow from a healthy infant. There is not the slightest objection to that method in my opinion. It is endorsed by the German government,³ and advised by them at the present day,

¹ See page 433 of the Journal.

² See Medical and Surgical History of War of the Rebellion, Part III, Medical Volume.

³ Extract from Decree of the Bundesrath of April 28, 1887.

Section 18, relative to the method to be taken for beginning a succession of animal vaccinations: "In the vaccination of animals there may be used, (a) humanized lymph taken from the vesicles of a primary vaccination, subject to the laws of the Bundesrath of June 18,

provided the infant be healthy in all respects, and it is as easy to obtain a healthy infant as a healthy cow. There is no evidence to show any real difference in the vaccine lymph thus produced, when two or three removes from the healthy infant, as compared with that which is obtained by continuous vaccination, beginning with the lymph derived from a case of cow-pox in the cow. You may vaccinate from an infant to a heifer to-day and back again indefinitely, or take a series of infants and vaccinate from one to the other, or a series of cows from one to the other; and no evidence is as yet given to show an actual difference in the character of the lymph produced in efficiency or protective power. One of the great reasons for the change was the possibility of communicating syphilis, which is a very rare occurrence. Dr. Corey, of London, submitted himself to be vaccinated from a syphilitic infant, in 1881, and went through the stages of syphilis himself.

I took up animal vaccination again during the epidemic of small-pox in 1872, and continued the practice some twelve years, but at no time using the method of extensive scarification spoken of to-night. I employed a simple incision not over one-fourth of an inch in length, and just going through the skin, making four incisions at once, with an instrument which I devised for the purpose.* For the last twelve or thirteen years I have had little to do with the practical side of the question in any way.

I have had some opportunity to study the methods that have been adopted abroad, and find that they differ in a great many points from the methods adopted here. In almost every country on the other side of the water the practice that has been advised by the committee to-night is in vogue, that is, to have the government take charge of the work. It is not usually a commercial business abroad. There are, it is true, a few private vaccinal institutes in France and some other countries, and lymph may be found for sale in some large cities, but the possibility of its being a trade or occupation or money-making business is largely removed, especially in Germany. Some twenty-four cities in Germany have their own vaccine institutions under the government of the country, the Imperial Board of Health having a general supervision. The most important is that of Berlin, and I think the next in size is in Cologne; others are in Munich, Hamburg, Frankfurt, and almost all the large German cities.

The German law upon this subject is quoted in full in "Wood's Reference Hand-book," Vol. VII. The method of preservation with ivory points is not much used abroad. It is a very convenient method. The lymph used abroad is chiefly the glycerinized pulp. It is, I think, the method advised by Dr. Warlomont, of Brussels, who might well be called the father of bovine vaccination. His own work in Brussels is so carefully conducted that every animal is slaughtered and examined to find out whether the animal is healthy before the lymph is sent out. That is not done in all places. In London, the work is under the care of the Local Government Board, and Dr. Corey, who has been connected with that work for the last ten or fifteen years is well known everywhere as an accomplished expert in such work. He has made, as many

as fifty thousand vaccinations of infants without a single failure, and does not believe in so-called insusceptibility of infants to vaccination.⁵ In England, the parents or guardians are obliged under penalty for refusal to bring the infants at the proper time to the station to be examined, to find out whether the vaccination has taken or not, and in that way they obtain the records. In Italy, the government assumes control of vaccination, but in a more limited manner as to lymph-production. So also in Austria, Sweden and in some other countries. The following provision is made in the Italian law:

ARTICLE 3. Animal lymph may be preserved by the medical officer of the province, either at an institute for the production of lymph established by the provincial authority, or at an existing private institute for the production of lymph which has received official recognition from the provincial authority. In either case the institute must be put under the supervision of the medical officer. The medical officer is also empowered to make use of the National Vaccine Establishment at the office of the Department of Public Health (in Rome). [From the Regulations issued at Rome, June 18, 1891.]

There is one other point upon which I should like to speak, in which there is a great difference in all foreign countries from the practice now in this country, and that is as to the time for collecting the lymph from the animal. The time may be perhaps most accurately stated in hours. One hundred and sixty-eight hours (7 days) is the time that has been employed most commonly in this country, that is, a cow or heifer is vaccinated upon a certain day of the week and the lymph collected upon the same day of the week following. I think there may be some instances where it is taken a day earlier, but in no place either in Germany, in Paris or in London is the time longer than six days, and often it is five days or even less. I will read a few of the places where the time is stated: Berlin often 72 hours, Hanover 96 hours, Munich at the end of the fourth or beginning of the fifth day, Dresden three and a half days, Strasburg 117 to 144 hours. In one case a period of six days is mentioned. There is a reason for the difference, and I have no doubt that the reason is of a commercial character, so far as American methods are concerned. The amount of lymph that can be collected on the seventh day is very much greater than on the fifth or sixth day; and, as a general rule, I have no doubt that the lymph collected on the seventh day is perfectly good to use, but not always. Frequently on the seventh day I have seen vesicles that not only had much lymph in them, but they had also a purulent appearance, and certainly it would not be desirable to use lymph of that character. It has been used, and no trouble may have supervened; but I can believe that that is one of the reasons why such lymph is regarded with suspicion by persons who have made a thorough scientific study of the subject unbiased by financial considerations. It seems to me it would be a wise thing on the part of this State to send some young medical man to study this whole subject for a period of six months, or more, if necessary: spending two months with Dr. Corey, two with Warlomont, and two with the best German authorities, who have made a scientific study of the whole question. I think we should gain very much by some such method as that.

1885; (b) animal lymph subject to the same conditions as humanized lymph; (c) the solid and fluid portions of the so-called natural cow-pox.

* Figures in Wood's Reference Hand-book, vol. vii, Art., Vaccination.

⁵ "I have vaccinated close upon 50,000 children, and have never seen a case of insusceptibility." Evidence before Royal Commission on Vaccination, vol. ii, p. 142, 1889.

I would go further than anything that has been said here upon one point. It has been stated that the buying and selling of vaccine lymph at low prices has a bad effect; but I believe it would be still better if it were to be given away freely to physicians. The State should furnish it, and should bear the whole expense and furnish it free; not outside of the State limits, but to persons within the State of Massachusetts, I mean to boards of health, to cities and towns, and to all public institutions in the State and to all physicians in the State, and do away utterly and entirely with the sale of vaccine lymph by middle-men, apothecaries and travelling agents, and have it issued directly from the vaccine institution to the persons who are to use it, free of charge. I would not go so far as to say it should not be sold; but I think it should be made so free that no financial hindrance should prevent the vaccination of children.

DR. BROUGHTON: I must confess that when we started to investigate this subject of vaccination I was not prepared to find so extensive a field for study. There is certainly more in it than we have been wont to believe. I am of the opinion that the profession as a whole has not paid due attention to many phases of it. The theme is so trite that even our medical schools have not always emphasized it sufficiently. My first thought, therefore, as a result of our limited study, is a feeling of criticism of the general attitude of physicians upon the whole subject. There is a vagueness of view and a certain looseness of expression among many that is unfortunate. For instance, we have some who are prominent in the profession, eminent for their ability and learning in other departments of medicine, who have been heard to say, perhaps in a casual way, that they do not believe in the necessity of re-vaccination. Doubtless such a remark may be made carelessly and without deep conviction behind it, but emanating from prominent men the remark is quoted, and perhaps exaggerated, and a certain amount of harm is done. My own feeling is that during the present epidemic of small-pox the anti-vaccination sentiment has in this community gained not a little ground.

My own interest was first aroused by individual observation. In our practice at Jamaica Plain we seemed to meet with a large number of severe arms. Upon inquiry, many of the profession were of the opinion that severe cases were unusually prevalent in the city and vicinity. We began to question why this was. I am going to speak plainly because we have not the slightest personal feeling and intend no injustice to any. As we inquired further, it seemed as if almost all the severe cases of vaccine were in those vaccinated by the city, and we found that the source of the virus was from the New England Vaccine Company. That led us to desire to look into the matter, and the Norfolk District appointed us a committee to investigate the subject. Dr. Gilbert has covered the ground, and I will only emphasize one or two points. It was admitted without the slightest hesitation by Dr. Cutler of the New England Company, that the lymph supplied by him was of a much more active character than any other virus in the market. He claimed that this was desirable. The poor were coming into the headquarters to be vaccinated, and they wanted something that would *take* every time. He criticised, however, the technique of vaccination as ordinarily done by physicians. He claimed that they frequently made too large abrasions, and the result was a very large

vesicle with a slough and a good deal of constitutional disturbance. We asked him why his vaccine lymph was more active than that from other sources, and I do not know that he could fully explain it. We queried whether it could be explained by the fact that the cows were four years of age, whereas in the other institutions the cows were younger; and, secondly, whether his method of vaccinating the cow — by the production of such large vesicles — does not produce a lymph that contains a greater variety of germs, and perhaps germs of a more active virulence. Adopting the plan suggested by Dr. Cutler, Dr. Perry vaccinated a baby with the New England virus making only a very minute abrasion and the result was a most beautiful and perfect vesicle, hardly larger than the end of a lead pencil, and it would seem as if possibly there was some basis for Dr. Cutler's statement that the severe arms are the result of improper methods of technique. I would say, in conclusion, that loose habits of vaccinating should be corrected. I have known of one or two cases where vaccinations have been made upon the inside of the thigh, a most inappropriate place. Many, we fear, make no effort to vaccinate upon a clean surface, and are not scrupulously careful as to the condition of the instrument used. The after-care of the abrasion and vesicle has also been largely neglected. The profession is more or less responsible for the incorrect and erratic views afloat in the community. Regular physicians should be more careful what they think, what they say and what they do in this whole subject. Severe "takes" and unpleasant complications can be largely prevented I believe by proper care, and thus popular prejudice will be allayed. The State makes vaccination compulsory. It would seem, therefore, that upon her should devolve the responsibility of providing a standard and uniform kind of virus.

My feeling is that a committee should present a bill to the legislature. This, if properly framed and supported, can ultimately produce some effect. If the State can control the production of virus many of the evils will be remedied.

DR. MARTIN: I am most heartily in favor of Dr. Abbott's suggestion of establishing a State vaccine institution similar to those in Europe. As far as I know I am the only member of this Society engaged in the production of vaccine virus.

In Europe this idea of using full-grown animals is not heard of. When my father brought the virus from France to this country, the system was to propagate it upon young heifers not over six months old. That system we adhered to for some time. The calves have to be fed on milk and yolks of eggs to keep them along. We found by increasing the age to eight or ten months they are old enough to eat hay and meal and they keep strong and recover quickly and well from the vaccination as a general rule.

In regard to the use of antiseptics. A good deal has been said about asepsis and antiseptics in relation to this matter. Cleanliness and neatness are as desirable in this, as any other specialty of medicine, but I do not think the fact should be lost sight of that this whole system of vaccination is an artificial production of disease and not the restraining, killing off of disease entirely, that is to say, any substance really antiseptic in its nature will destroy the effect of the vaccine virus. The use of perfect cleanliness at the time of vaccinating or taking points should be insisted on.

Absolute cleanliness while the vesicles are maturing is practically almost out of the question, that is to say, there is in any stable a certain amount of dust and *débris* of straw, etc., which make a sort of coating over the vesicle; but when the points come to be taken, that objection is practically removed because the animal is put upon the table and thoroughly washed, the part vaccinated is thoroughly washed with warm water, then the crust is removed and under that there is usually a little whitish sort of material, soft, pulpy, not offensive pus, no odor to it, — that is removed with a cloth and the vesicle thoroughly washed with a sponge to make it perfectly clean, and that I am always very particular about. If there was any dirt of any sort about the vesicle visible to the naked eye it would be shown on the point at once.

DR. ABBOTT: I should like to allude to one point. Dr. Martin is right with regard to the age of animals. I do not think any animals are used on the other side more than nine or ten months old. The average is probably about three months, and even younger than that. By the terms of the German law, calves of five weeks old and upward are preferred. The weight is more often given than the age. One point in regard to vaccine farms in this country. I have an advertisement here in which the origin of the lymph used is stated to be the "only authentic case of spontaneous cow-pox in America."

I think we have got beyond the idea of infective diseases, like cow-pox and small-pox, being spontaneous. The fact that we cannot find a definite cause for a case of disease cannot be regarded as a proof that a cause does not exist. The cases of cow-pox occurring accidentally or incidentally in this country are not one, but many. I have visited and seen twenty-five or thirty in the cow, and eight or ten in one herd. The latter were in Lexington, in 1873. It was determined to be genuine by the appearances of the eruption, and by the fact that in some of the cases the animals were vaccinated afterwards and would not take. I have seen just such cases as Jenner described among dairy-men who milk the cows, with disease upon their thumbs and fingers exactly such as are figured in the old plates. The advertising of vaccine lymph from *spontaneous* cow-pox is a practice not only unworthy of an intelligent profession, but contrary to all observations as to the natural history of infectious diseases. The cases to which I have referred occurred always during epidemics of small-pox and at no other time. A portion of them occurred in the great epidemic of 1872-73, and the others in the milder epidemic of 1880-81.

DR. A. P. CHADBOURNE presented an account of

GASTRIC AND RESPIRATORY SYMPTOMS FROM INHALATION OF THE DUST OF CURLED HAIR.⁶

DR. ABBOTT: There are in this paper some points which may explain similar symptoms that occurred in a factory at Hyde Park. I have visited this factory once or twice. There is a report of anthrax having occurred among those workers twenty years ago.⁷ Cases then occurred occasionally of genuine anthrax coming from the curled hair from Russia, that had been shorn from animals that died from that disease. They were almost the only cases of anthrax that we have had, except a very few in towns where tanning of hides is conducted. There were some unexplained symptoms

among those people, and also in a smaller epidemic eight or nine years ago. The people were sick much longer than with anthrax, with respiratory, and also with digestive symptoms. The respiratory symptoms may have been produced by just such causes as Dr. Chadbourne has noted. There was opportunity in that factory for great improvement, and it brings up a question which I wish might be made the subject of legislation, that is, compelling all people who own factories where dusty operations are carried on to a large extent, to ventilate them on the best principles.

DR. CHADBOURNE: I would say in connection with anthrax that since the cases of this disease, mentioned by Dr. Abbott, the hair is "disinfected," but how thoroughly this is done I do not know. The horse-hair used is chiefly from the West, Mexico, South America and Tartary. The pigs' hair comes from about here. This patient told me that almost all of the men working in the factory for a considerable time suffered from the same trouble that he had, the stomach being decidedly more troublesome than the lungs; and this is the point I wish to emphasize, that in this patient symptoms of a chronic interstitial fibroid change were not apparent, but that there are other symptoms that may and perhaps do occur oftener than we think of or attribute to this cause.

THE OBSTETRICAL SOCIETY OF BOSTON.

CHARLES W. TOWNSEND, M.D., SECRETARY.

MEETING March 10, 1894, the President, DR. CHARLES M. GREEN, in the chair.

DR. A. WORCESTER read a paper entitled,

WHAT MIGHT BE DONE BY THE OBSTETRICAL SOCIETY TO ADVANCE THE TRAINING OF NURSES.¹

DR. E. H. BRIGHAM said that a large field was opened for obstetric nurses, as only the very well-to-do can afford to pay the present prices. He believed that as time goes on the number of obstetric nurses will so increase that prices will have to come down.

DR. F. H. BROWN thought that the suggestion of post-graduate courses was an extremely good one. Nurses come out of many hospitals as specialists, and need lectures on other branches.

DR. EDWARD REYNOLDS thought that specialism among nurses made the best nurses. He would suggest one method of solving the problem of expense by employing the best obstetric nurses for the first two or three weeks of the lying-in period, and then having superior nursery-maids for the next four or six weeks, who had been trained at some children's institution.

DR. J. G. BLAKE suggested that nurses might be trained in the out-patient department of the Lying-in Hospital who would be willing to go out as obstetric nurses for a moderate fee.

DR. J. STEDMAN said there was a great call for nurses at ten or twelve dollars a week.

DR. CLARENCE J. BLAKE then spoke on the subject of graduate instruction for nurses, giving a sketch of the Graduate Nurses' Association.

A committee of three, consisting of Dr. Davenport (Chairman), Dr. Edward Reynolds and Dr. Washburn, were then appointed by the chair to consider the advisability of the Society examining obstetrical nurses for registration, as proposed by Dr. Worcester.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, MAY 3, 1894.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

UNEMPLOYED MEDICAL MEN.

We hardly design to take the onward march to Washington of Coxey's army of tramps as a topic on which to "point a moral or adorn a tale." Nor is it a part of our present purpose to forecast the outcome of this enterprise (whether serious or foolish) or to speculate on the causes or remedies. Alienists may regard the whole movement as a "craze"; others will look upon it as the legitimate result of certain socialistic theories of political economy which of late years have been widely enunciated. On this point we do not intend to expatiate. We shall only touch upon a certain aspect of the subject which most concerns and interests medical men.

One of the causes of the unrest and discontent which pervades society is that multitudes have been educated to regard manual labor as degrading, and to shirk hard labor generally. There is a preponderance of half-educated men in communities, unwilling to engage in or unfit for humble callings, but with enough smattering of letters to make them effective nuisances to society; from this class come too many of our political agitators, and, we are sorry to say, some of our Congressmen. In Germany the state of things is so bad as to justify Mr. Dawson's gloomy picture: "Twenty-two seats of learning are yearly turning out studied men in thousands, and the unfortunate 'studied men' are lucky if at the age of thirty-five they are earning the wages of English bank clerks. The paternal State finds money for universities and looks to the qualifications for the professions and the civil service; but that paternal State cannot provide its carefully examined would-be-lawyers and doctors and civil servants and teachers with briefs and patients and posts and pupils; and, as a consequence, the educated unemployed increase mightily in numbers year by year. Still more formidable are the 'breakages,' the horde of superficially book-learned young fellows of the middle and lower middle ranks, whom stupidly ambitious fathers have sent to universities (the State aiding) to

fail in examinations when they ought to be selling groceries or hoeing potatoes."¹

The evil complained of exists equally in this country, and it is not too much to affirm, with a writer in the journal from which we have quoted, "that college classes are too large, and that engineers, architects, chemists, lawyers, doctors and druggists, qualified and semi-qualified, exist in far too great proportion to the rest of the community."

In its application to the medical profession, this statement is justified by reference to every city and village in New England. The latest statistics, in fact, give a constituency of only about four hundred and fifty inhabitants to each physician. In some communities the ratio is even less than this. Nor is the prospect much more inviting in the West, if we may trust a correspondent of the *Medical Record*: "As a result of our rapid railroad building, new villages are being located every few days, and it is not the rarest of sights to see one or two physicians hovering like shadows around a town which for the time being exists only on paper. These 'too previous' aspirants frequently board at country houses, daily visiting the patch of waving prairie grass, the site of the prospective metropolis, and waiting sometimes for weeks before buildings are erected in which offices can be had." This same writer gives a gloomy picture of the sharp competition with quacks in Kansas and neighboring States, and other drawbacks, and of the meagre incomes which even sober, industrious, reputable physicians receive, and draws the obvious conclusion that in the far West, as everywhere, the profession is greatly overcrowded.

The thousands of graduates who this present spring season will go forth from the very numerous medical schools of this country cannot but augment the great army of the unemployed. The recent graduate, unless he has gone into medicine for the love of the science and art of healing, and wisely, perhaps, decides to stick to the hospitals for a few years, or for life, must (unless Fortune favors him above his competitors) wait long and patiently before he can obtain practice. To many, such long waiting (involving, it may be, the sacrifice of the best years of their manhood) is very irksome; and this is especially the case when the physician is poor and dependent on his practice for his support.

We have no more to say at this time than to advise all young men and women contemplating the study of medicine to weigh well the chances of success in this profession, and ask themselves whether they are prepared to wait, it may be years, for success? If money-making is the object, they would probably do better to repudiate a calling so little lucrative.

Again, unless the student is prepared to take more than the old-fashioned, two-years' winter's course, we would say emphatically, Don't enter medicine. An instructive illustration on this point is furnished by Dr. John H. Ranch in his last "Report on Medical

¹ Popular Science Monthly, May, 1894.

Education and Medical Colleges in the United States and in Canada." He says: "During the past nine years I have followed up with exceptional interest and care the careers of 789 out of 1,000 physicians who studied four years and attended at least three terms before graduating. These are, with few exceptions, the successful and prominent members of the profession in the different communities in which they reside. They are well equipped by general education, by an ample period of professional study, by didactic and clinical instruction, and by hospital practice. They are successful, as a rule, because they have fitted themselves to command success."

THE POISONOUS PROPERTIES OF ABSINTHE AND ITS CONGENERS.

THE use of absinthe and kindred bitters, the class of appetizers called by the French *apéritif*, we are glad to believe is still small in our country, and it is to be hoped the habits of the people may not suffer any change in this respect. We have undoubtedly enough bad habits of our own without importing those of other countries. At the same time, it is well to be forewarned, and we cannot admit the great stream of foreign immigration which has been pouring in upon us without the accompaniment, in a certain measure, of the manners and customs.

Absinthe, as a drink, has long had a bad name. Its evil effects upon those addicted to its constant use have often been painted in lurid colors, which have sometimes been supposed to be exaggerated. Few, however, probably know precisely what the ingredients of absinthe and its congeners are, nor what are precisely their physiological effects. Charles Mayet has lately made a clear statement in *Le Temps*, of Paris, in regard to the composition and the physiological effects of the component parts of absinthe, liqueur, bitters, and vermouth, which, in view of their great consumption in some quarters, is not without a vital interest. His article is based upon the generally accepted investigations of MM. Cadéac and Meunier.¹

The liqueur sold under the name of absinthe contains not only the essence of the plant from which it is derived, but divers other essences varying in kind and quantity.

Dr. Lunier presents a formula of three extracts of absinthe obtained by distillation, which are generally employed in commerce and known as *fine*, *half-fine* and *ordinary*. These portions are for five and a quarter gallons of absinthe.

	Ordinary	Half-fine	Fine
Leaves and flowers of the great absinthe	600	600	600
Leaves of little absinthe	200	125
Balm-mint (mellise)	125	125	200
Flowers of hyssop	100	100	225
Angelica-root	25	..
Green anise	400	800	1,000
Badiane	400	225
Fennel	250	250
Coriander	225	225
Alcohol (85%)	11,750	12,000	16,300
Water	9,500	8,000	4,000
(Quantities given in grammes.)			

¹ Experimental Researches in Essences, Paris, 1892.

An infusion is made of these plants and seeds during twenty-four hours in a portion of the alcohol; it is then distilled with the water, and to the product is added the remainder of the alcohol and water. To obtain the green color indigo is often used, and is heightened with burnt sugar and saffron. A little alum is added to hold the color in suspension.

In the formula given there are three plants of the group which produce epilepsy, namely, absinthe, hyssop and fennel, and a plant of the stupefying group, the angelica.

The guinea-pigs utilized by Cadéac and Albin Meunier in studying the action of the vapor of the essence of hyssop, were victims of the incense of this poetic and biblical plant. In one instance it was administered solely by the respiratory organs. A guinea-pig placed under an observation bell glass, staggers, exhibits spasmodic convulsions, passes into extreme opisthotonos, and dies at the end of an hour and a half from having simply breathed the perfume of a few drops of the essence of hyssop. Another experiment consisted in injecting into the veins of a dog a few drops of the essence of hyssop, which resulted in a violent attack of epilepsy. Absinthe produced the same effect.

Four grammes of the essence of hyssop given upon an empty stomach suffices to kill a dog weighing sixteen pounds in thirteen hours. Six grammes will kill a dog of thirty-two pounds three hours after ingestion. One gramme will kill an animal weighing one hundred and fifty grammes. A man cannot absorb two grammes of this essence of hyssop without danger of falling in an attack of epilepsy. One gramme will cause numbness, ocular troubles and trembling. The essence of hyssop is then, like absinthe, a formidable poison.

The fennel, which Charlemagne commanded to be cultivated, and which the Russians, the Armenians and the Tartars consume as a salad as we do the onion and the water-cress, also figures in the series of plants which enter into the composition of absinthe. Cadéac and Meunier, who have experimented with the essence of this plant upon divers animals, remark that the epileptogenic properties of the essence of fennel are unquestionable. Its activity is inferior to that of hyssop and absinthe, but it is far from innocuous.

Angelica-root, which is put in the category of the excito-stupefacients, is recognized as having the property of stimulating the mental faculties and the muscular energy. Its salutary effects, however, are transient: those that are dangerous soon become preponderant. The prolonged fatigue, the somnolence, the unconscious enfeeblement of all the faculties, are finally the certain inheritance of all who misuse it.

From these investigations M. Mayet concludes that we are amply justified in placing the liqueur of absinthe, compounded of these divers essences, among the poisonous drinks that are particularly dangerous.

Passing to the bitters, the formula used the most in France is for five and a quarter gallons of bitters, namely, Dr. Decaisne's formula:

Anise 80 grammes, orange peel 80 gr., calamint 80 gr., juniper berries 80 gr., sage 80 gr., great absinthe 60 gr., angelica 40 gr., mint 40 gr., lavender flowers 40 gr., clove 20 gr., alcohol (80 per cent.) 650 gr., sugar 600 gr., water 650 gr.

In this list, the absinthe and the angelica already known make their appearance.

For an analysis of the sage, the mint, and the lavender the previous authorities are again referred to. They tell us that the sage is a poisonous and epileptogenic factor. If a guinea-pig is put into an atmosphere saturated with the vapors of this essence, the experiment is attended by all the successive symptomatic phases observed after the injection of small but strong quantities of this essential oil into the venous circulation of a dog: a lively excitation, sudden starts, shakings, muscular rigidity, drunkenness, a fall, and then epileptic convulsions. This is fresh evidence that the essences produce by their perfume absolutely the same effects as when taken into the stomach. The poisonous character of the sage, however, varies with the place of its origin. Some specimens are but slightly poisonous. Considerable doses of such do not cause in man more serious troubles than affection of the sight, the subjective sensations of heat and cold, of nausea, of dizziness and tingling, but associated in the bitters with epileptogenics and other poisons, there is much more to fear. There is strong reason to think, however, that the more poisonous essences of sage are more commonly employed in the fabrication of bitters; such were procured by Messrs. Cadéac and Meunier in a warehouse at Leipzig, which given in a dose of five centigrammes caused a violent attack of epilepsy in a dog weighing sixteen to eighteen pounds, which was soon followed by death.

A small quantity of calamint, for example, thirteen grammes to twenty-six gallons, will be found grateful to our organic functions. The ingestion of a small quantity of this essence renders our faculties alert and active, and gives to the lower animals a sprightly and intelligent air. They seem perfectly satisfied with conscious strength and mastery; they move about with pleasure, and promenade with a proud and conquering gait; but if the dose is strong, drunkenness and epilepsy follow. It will be well to remember that in the formula for distillation there are eighty grammes of calamint to five and a quarter gallons, or nearly four grammes to a quart.

The effect of mint is in dispute. Its essence is slightly poisonous. An excitant for some, it is antispasmodic and tranquilizing for others. Soothed by a feeble dose, a large one will excite. Twenty grammes introduced into the stomach of a dog will cause death by asphyxia, with convulsions.

With regard to lavender, an equally integrant part of the bitter, Cadéac and Meunier declare it to be unquestionably stupefying. It is a powerful poison: two and a half grammes of the essence of lavender injected into the veins of a dog weighing thirty-eight pounds will kill him in four or five minutes.

Having thus obtained positive information in regard to absinthe and the bitters, we are told what is con-

tained in vermouth, and arquebusade water (*eau d'arquebuse*). Vermouth (a German word signifying absinthe) is less a liqueur than a white wine, alcoholized and aromatized with divers plants. The formula for that commonly consumed in France, is as follows:

For twenty-six gallons of vermouth (100 litres): white wine 95 litres, alcohol (85 per cent.) 5 litres, great absinthe 125 grammes, gentian 80 gr., angelica-root 60 gr., thistle 125 gr., calamint 125 gr., alder 125 gr., little centaury 125 gr., germander 125 gr., 15 nutmegs and 6 fresh oranges cut in slices.

In this formula we still find the absinthe epileptogenic and toxic; the angelica, in the first instance excitant, and then somniferous and depressing; and the calamint an excito-stupefacient.

In regard to vulnerary, or arquebusade water, it is the most complete expression of a type of liqueur which is aromatic and poisonous. The formula for the essence for 100 litres (26 gallons) of alcohol (60%), is:

Essences of absinthe 7 grammes, of angelica 25 gr., of basil 1½ gr., of calamint 1½ gr., of fennel 50 gr., of hyssop 13½ gr., of marjoram 16 gr., of balm-mint 3½ gr., of mint 12 gr., of rosemary 34 gr., of rue 6 gr., of savory 27 gr., of sage 48 gr., of wild thyme 12 gr., of thyme 12 gr., of hypericum 1 gr., of lavender 97 grammes.

All these essences are noxious; all, in certain doses, with diverse manifestations, poison and kill.

"Here, in their brutality" says M. Mayet, "are the proportions of the powerful poisons established by experience for these essences, which figure in French cordials, aperitives, and in the greater part of liqueurs. In drinking this liqueur — the type of all those spoken of — the mother as well as the young girl is preparing to become the parent of candidates for epilepsy. As regards the man, after drinking there is a momentary increase of strength, a transitory excitation which will be very quickly followed by an intolerant, impulsive and disputatious disposition, and which, if exaggerated by abuse of the liqueur makes him a violent, stubborn, quarrelsome and bad citizen."

MEDICAL NOTES.

SMALL-POX IN CHICAGO. — The total number of cases of small-pox in Chicago during the month of April was five hundred and eight. There is an average of about twenty new cases daily. The public schools have been ordered closed for a week upon the recommendation of the Board of Health.

AN EPIDEMIC OF TYPHUS FEVER IN PRAGUE. — Since the middle of January a considerable epidemic of typhus fever has prevailed in Prague which is only just beginning to subside. The causes lay in the filthiness of the houses, the accumulation of excreta in the canals, the insufficient sanitation of the streets, and, particularly, the abominable character of the water-supply.

THE CHOLERA AT LISBON. — Dr. Montaldo, the chief medical director of the Spanish Government, who was sent to Lisbon to inquire into the character of the disease now raging there, which Portuguese medical officials designated as "cholérine," reports that the

disease is true Asiatic cholera. On the 25th of April there were eighty-four new cases of the disease, since when the daily number of new cases has fallen to about sixty. At present there are about four hundred patients under treatment. The Spanish Government has established additional sanitary stations along the Portuguese frontier and has ordered an inspection of the condition of Spanish towns.

AWARD OF THE WATSON MEDAL. — Dr. S. C. Chandler, of Boston, has been awarded the Watson Medal of the National Academy of Sciences at Washington for his work in astronomy. This medal has been awarded but four times in the last twelve years, the last being in 1892 to the distinguished German astronomer, Auwers.

SURGICAL INSTRUMENTS ARE DUTIABLE. — The Treasury Department has ruled, through its Board of General Appraisers, that instruments used by physicians or surgeons for the purpose of carrying on their profession are mechanical instruments, mere tools, and cannot be classed as scientific instruments on the free list, but must be assessed for customs dues.

A PRIZE OFFERED TO NEW YORK PHYSICIANS. — The Medical Society of the State of New York offers a prize of one hundred dollars for the best original essay on any medical or surgical subject. Competitors must reside in the State of New York and be members of a County Medical Society. Essays are to be sent to the Chairman prior to January 1, 1895.

THE MINNESOTA INSANITY LAW UNCONSTITUTIONAL. — The law of the State of Minnesota regarding the commitment of insane persons to asylum care, which was passed in 1893 has been declared by the court to be unconstitutional. This decision is likely to cause considerable trouble as about five hundred persons have been committed under its provisions, and the next session of the legislature does not meet until January, 1895, till when no relief can be had.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — During the week ending at noon, May 2, 1894, there were reported to the Board of Health of Boston the following numbers of cases of acute infectious disease: diphtheria 34, scarlet fever 49, measles 7, typhoid fever 7, small-pox 6 (no deaths). There are now 10 cases of small-pox in the hospital.

CAMBRIDGE SCHOOL CHILDREN'S FEET. — The School Board of Cambridge, Mass., has granted Dr. G. W. Fitz of the Harvard University gymnasium permission to take measurements of the feet of school children in all the public schools of the city upon obtaining consent of the child or its parents. So far there has been practically no objection on the part of the children examined.

A BEQUEST TO THE WATERBURY HOSPITAL. — The will of the late Charles Scott, of Washington, D. C., bequeaths the sum of five thousand dollars to the Waterbury, Conn., Hospital.

ELECTION OF OFFICERS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY. — The following officers were chosen for the coming year at the annual meeting of the Suffolk District Medical Society, April 28th: President, A. L. Mason; Vice-President, John G. Blake; Secretary, Herbert L. Smith; Treasurer, Edward M. Buckingham; Librarian, B. J. Jeffries; Commissioner of Trials, C. W. Swan; Member of the Nominating Committee of the Massachusetts Medical Society, W. L. Richardson; Committee of Supervision, F. Minot, W. Ingalls; Committee on Social Meetings, H. Williams, G. A. Leland, E. Reynolds, P. Thorndike; Censors, F. H. Davenport, H. F. Vickery, F. B. Harrington, R. W. Lovett, E. O. Otis.

NEW YORK.

COLLEGE OF PHARMACY COMMENCEMENT. — The sixty-fifth annual commencement of the College of Pharmacy of the City of New York was held at Carnegie Music Hall on April 25th. The degree of Ph.G. was conferred on a class of 128 graduates by the President, Samuel W. Fairchild, and an address was delivered by the Rev. John W. Brown, rector of St. Thomas's Church.

A NEW HOSPITAL FOR CONSUMPTIVES. — The organization of a new hospital and dispensary for consumptives has just been perfected. At a meeting held for the purpose on April 26th at the house of the President of the Board of Managers, Mrs. Richard Irvin, Dr. A. L. Loomis made an address, in which he spoke of the inadequacy of the treatment of tuberculosis at the general hospitals, and of the desirability of institutions providing the most approved means of treatment. In speaking of the proposed undertaking, he said: "Where a change of air is necessary, the dispensary ought to be able to send them to a sanitarium near the mountains. Boston has such an institution, and it has had the best of results. The lives of many shop-girls and clerks who cannot receive proper treatment as things exist now might be saved by such an institution." A house has been secured on West 38th Street for the commencement of the work, and it will be opened early in May. It will be supplied with the pneumatic cabinet and other appliances for treatment, and Dr. Charles E. Quimby, who has been associated with Dr. Loomis for a number of years, will be the attending physician. There will be a board of lady managers and an advisory medical board, consisting of Drs. A. L. Loomis, Charles McBurney, Henry F. Walker, William M. Polk and A. A. Smith.

Miscellany.

THE TREATMENT OF SEA-SICKNESS.

DR. CHARTERIS of Glasgow reported in 1893¹ that favorable results had been obtained from the use of chlorobrom in sea-sickness. He now states,² as his conclusion from a study of three hundred cases, that if

¹ *Lancet*, February 15, 1893.

² *Ibid.*, April 21, 1894.

suitably administered it has a decided prophylactic value for both long and short voyages.

"To ensure success in this treatment, it is essential that the *prima vie* should be freely moved for two successive nights before embarkation, and that for the first two or three days of the voyage the traveller should eat 'spare and dry,' avoiding above all things soup, sweets and pastry. A full dose of chlorobrom (one tablespoonful and a half for a male and one tablespoonful for a female) must be taken for the first three nights of the voyage. After this period a further use of the solution will probably be found to be unnecessary and all restrictions of diet may be removed. Idiosyncrasis of the patient may prevent in very rough weather absolute freedom from sea-sickness, but on the evidence produced there seems to be every probability that in the majority of cases immunity may be obtained.

"In short voyages, when the steamer leaves, perhaps at 10 P. M., the passenger should immediately retire to rest, and take one of the doses mentioned. In a shorter passage across the Channel a teaspoonful should be taken before going on board. By following these directions immunity from sea-sickness is obtained in the great majority of cases, but if they be not followed it is to be remembered that chlorobrom has no effect in arresting an outburst of vomiting. If it is given in a teaspoonful dose every ten minutes until a tablespoonful and a half or a tablespoonful have been taken, it will almost invariably check retching and depression."

OBITUARY. — THEODORE METCALF.

MR. METCALF was born in Dedham, Mass., in the year 1812, and was a son of Judge Theron Metcalf, who lived to be over ninety years old. In 1826, he began an apprenticeship at Hartford, Conn., where he remained for ten years, the last three as partner.

Leaving there in 1837, he established the apothecary store at No. 39 Tremont Street, Boston, which has, with the exception of the years between 1845-1855 (most of which were spent abroad), been continually under his personal supervision. Combining with his inflexible integrity and steadfast devotion to his adopted calling, an intimate knowledge of drugs, both crude and prepared, he was influential in elevating the position of the pharmacist from the rank of a tradesman to that of a professional man.

The natural result of his persistent and consistent endeavors was the establishment of an immense business, to which he was attentive to the close of his long career. Mr. Metcalf's first associate in business was Mr. Jos. Burnett; one of more recent years was Mr. Thomas Doliber. He had the intuitive perception of character which enabled him to surround himself with the best executive ability, and some years ago associated with himself a number of his leading employees, those in charge of the different departments, and incorporated the Theodore Metcalf Company, of which he was Treasurer at the time of his death.

Mr. Metcalf has been very active also in affairs outside of his business, and of a very charitable disposition, and always ready to assist personally and financially all objects of a worthy and charitable nature; and many young men will testify as to the great assistance and encouragement given by him which enabled them to successfully prosecute their aims in life.

Mr. Metcalf was for more than thirty years the treasurer of the Channing Home, the first president of the Boston Druggists' Association, one of the founders of the American Pharmaceutical Association, one of the promoters of the Massachusetts College of Pharmacy, trustee of the City and St. Elizabeth's Hospitals, and one of the trustees and first president of the Catholic Union.

METEOROLOGICAL RECORD.

For the week ending April 21st, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Date.	Baro- meter	Thermom- eter.			Relative humidity.			Direction of wind.		Velocity of wind.		Weath'r. •		Rainfall in inches.

Deaths reported 2,541: under five years of age 926; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fever) 358, acute lung diseases 459, consumption 282, diphtheria and croup 151, scarlet fever 48, measles 46, whooping-cough 27, typhoid fever 27, diarrhoeal diseases 25, small-pox 11, erysipelas 9, cerebro-spinal meningitis 8, malarial fever 6.

From whooping-cough New York 12, Boston 5, Washington 3, Philadelphia, Brooklyn, Cincinnati, Cleveland, Milwaukee and Lowell 1 each. From typhoid fever New York and Philadelphia 7 each, Cincinnati 4, Boston, Washington and Milwaukee 2 each, Brooklyn, Cleveland and Haverhill 1 each. From diarrhoeal diseases New York 9, Brooklyn, Cincinnati, Lowell and Gloucester 2 each, Philadelphia, Boston, Washington, Cleveland, Milwaukee, Worcester, Somerville and Salem 1 each. From small-pox Brooklyn 7, New York 3, Boston 1. From erysipelas

New York 4, Philadelphia and Brooklyn 2 each, Boston 1. From cerebro-spinal meningitis New York 4, Gloucester 2, Cleveland and Worcester 1 each.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 21, 1894, TO APRIL 27, 1894.

MAJOR VALERY HAVARD, surgeon, is relieved from duty at Fort D. A. Russell, Wyoming, and ordered to David's Island, N. Y., for duty at that depot, relieving MAJOR JOSEPH R. GIBSON, surgeon.

MAJOR GIBSON, on being relieved by MAJOR HAVARD, is ordered to Fort Snelling, Minnesota, for duty at that station, relieving MAJOR CHARLES K. WINNE, surgeon.

MAJOR CHARLES K. WINNE, on being relieved by MAJOR GIBSON, is ordered to duty at Fort McHenry, Maryland, relieving CAPTAIN CHARLES B. EWING, assistant surgeon.

CAPTAIN EWING, on being relieved by MAJOR WINNE, will report for duty at Jefferson Barracks, Mo.

CAPTAIN WILLIAM L. KNEEDLER, assistant surgeon, will, in addition to his present duties as post surgeon, Fort Mason, California, perform that of attending surgeon, San Francisco, Cal., until further orders.

Leave of absence for one month, to take effect on or about April 24, 1894, is granted CAPTAIN JAMES D. GLENNAN, assistant surgeon.

CAPTAIN NATHAN S. JARVIS, assistant surgeon, will be relieved from duty at David's Island, N. Y., upon the arrival of CAPTAIN SAMUEL Q. ROBINSON, assistant surgeon, and will report in person to the commanding officer, Willett's Point, New York, for duty, relieving CAPTAIN WILLIAM P. KENDALL, assistant surgeon.

CAPTAIN KENDALL, upon being so relieved, will report in person for duty at Fort Columbus, New York.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE FIVE WEEKS ENDING APRIL 21, 1894.

MURRAY, R. D., surgeon. To inspect quarantine stations of Florida. April 17, 1894.

BAILHACHE, P. H., surgeon. To proceed to New London, Conn., as inspector. April 18, 1894.

MEAD, F. W., surgeon. To report to chairman, Committee on District of Columbia, U. S. Senate, for special duty. April 7, 1894.

CARMICHAEL, D. A., passed assistant surgeon. To report to medical officer in command at San Francisco, Cal., for temporary duty. April 11, 1894. To proceed to Fort Townsend, Washington, and inspect Marine-Hospital Service and Quarantine Service. April 21, 1894.

BROOKS, S. D., passed assistant surgeon. To proceed to Chicago, Ill., for temporary duty. April 3, 1894.

BRATTON, W. D., passed assistant surgeon. To report at Bureau. April 18, 1894. To proceed to Reedy Island Quarantine and await orders. April 20, 1894.

VAUGHAN, G. T., passed assistant surgeon. Detailed as chairman, Board for physical examination of candidates, Revenue Marine Service. March 19, 1894.

COBB, J. O., passed assistant surgeon. To proceed to Seattle and Tacoma, Wash., as inspector. April 12, 1894.

WERTENBAKER, C. P., passed assistant surgeon. Granted leave of absence for two months. April 3, 1894.

BROWN, B. W., assistant surgeon. Granted leave of absence for six days. April 7, 1894.

DECKER, C. E., assistant surgeon. Placed on "waiting orders." April 1, 1894.

STRAYER, EDGAR, assistant surgeon. To proceed to Vineyard Haven, Mass., for temporary duty. April 4, 1894.

OAKLEY, J. H., assistant surgeon. To proceed to San Francisco Quarantine Station for temporary duty. April 11, 1894.

PROCHAZKA, Emil, assistant surgeon. To proceed to Cleveland, Ohio, for temporary duty. April 2, 1894.

SOCIETY NOTICE.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—The next meeting will be held at 19 Boylston Place on Monday, May 7th, at 8 o'clock.

Regular Reader: Dr. W. B. Hills, "Chronic Arsenical Poisoning—Analysis of Urine in 300 Cases." Discussion opened by Dr. E. S. Wood.

An important matter of business will come up for discussion. J. G. MUMFORD, M.D., Secretary.

NORFOLK DISTRICT MEDICAL SOCIETY.—The annual meeting will be held at the Norfolk House, Eliot Square, Roxbury, Tuesday, May 8th, at 12.30 P. M.

The Board of Censors will meet at the same place at 12.45 P. M.

The examination of candidates will take place one week later, on Tuesday, May 15th, at 7 P. M., at the office of the Secretary, 130 Warren St., Roxbury. The written examination will begin at 7 P. M., the oral at 8 P. M. After the dinner the "Annual Address" will be given by W. S. Everett, M.D.

The Secretary particularly requests that all who expect to attend the annual meeting to notify him, that he may be able to make suitable provision for the dinner.

JAMES C. D. PIGEON, M.D., Secretary.

APPOINTMENTS.

DR. JOHN L. MORSE has been appointed physician to out-patients to the Boston City Hospital.

DR. W. P. DERBY has been appointed surgeon to out-patients to the Free Hospital for Women.

DR. JAMES M. JACKSON has been appointed assistant pathologist to the Free Hospital for Women.

DRS. JOHN L. AMES and CARROLL E. EDSON have been appointed visiting physicians to the children at St. Mary's Infant Asylum and Maternity Hospital.

RECENT DEATHS.

THEODORE METCALF, a well-known Boston druggist, died in Brookline, Mass., April 26th, aged eighty-two years.

JOHN H. PATTERSON, M.D., M.M.S.S., died in Harwich, Mass., April 29th, of scarlet fever, contracted while attending a family where three children were ill with the disease. He graduated from Dartmouth College in 1886 and from the Dartmouth Medical School in 1889.

ALBERT DAY, M.D., M.M.S.S., died in Melrose Highlands, Mass., April 26, 1894, aged seventy-two years. He lost his father when only a lad and was obliged to go to work, studying at night to obtain his education. He early became an earnest advocate of the cause of temperance in the use of alcohol. In 1856 he was a member of the State House of Representatives and worked hard for the establishment of an asylum for the care and cure of inebriates. On the organization of the Washingtonian Home he was made its superintendent. He entered the Harvard Medical School to make himself more fitted for his work, and graduated in 1866. In 1868 he took charge of the asylum at Binghamton, N. Y., and afterwards established a private asylum. In 1875 he returned to the Washingtonian Home where he remained till a year ago.

ARTHUR HILL HASSALL, M.D., died in San Remo, April 10th, aged seventy-seven years. He was educated at Dublin under the care of his uncle, Sir James Murray, and became a most careful and enthusiastic student with the microscope. His early years in practice in London were largely devoted to the study of histology at St. George's Hospital. In 1852 he published a book on "The Microscopic Anatomy of the Human Body." It contained some four hundred illustrations of his own drawing and was the first complete book on this subject in the English language. He next turned his attention to food adulterations and published in 1857 an exhaustive treatise on "Adulterations in Food and Medicine." In 1866 his health was so affected by the beginning of his fatal illness, consumption, that he was obliged to move his residence to the Isle of Wight. So soon as he had rallied from the hæmoptysis he took up his work in such a new line as was suited to his strength and organized that model system of hospital control of phthisis—known as the separate or Ventnor system. He remained the consulting physician to this National Hospital for Consumptives at Ventnor until his death. In 1877 his health required him to live still farther south and he went to San Remo. Here he retired from active practice, but spent much time in the study of climatic conditions, and in extending his microscopic investigations. He published an autobiography last year entitled "The Narrative of a Busy Life."

VARIOLA.¹

BY S. G. WEBSTER, M.D.

DR. ROBERT R. LEO distinguishes between variola and varioloid: "In variola vera will be included all those cases in which the more or less thickly standing pustules show complete development, confluence and their sequelæ resulting therefrom, and in which, shortly after the critical defervescence of the eruptive fever, a new fever of greater or less severity (the suppurative fever) begins. In varioloid, on the other hand, will be included all cases in which the pustules, more or less scattered, do not attain the highest development, but begin their retrocession earlier, and in which after the rapid defervescence of the fever to an unusually low temperature, this gradually returns with slight accidental exacerbation or slight morning remissions and evening exacerbations to the normal height and there remains."²

The first four patients who entered the hospital were from the same house; all had been exposed to the disease by taking care of a friend who had died. None had ever been vaccinated.

CASE I. John S., age twenty-two, blacksmith, was admitted in the afternoon of October 26, 1869. He was taken sick on the 23d. Backache was the chief symptom complained of. On entrance his face was red and swollen, eyes red. No eruption. Tongue coated. Pulse 102.

October 27th. He passed a restless night; passed blood from his bowels several times during the night. There was considerable dyspnea at times, again the respiration was quiet. The whole surface of the body was livid. Occasionally he started up and stood up to assist himself or to get relief, and then fell back on the bed. Pulse imperceptible. Mind seemingly not affected; he answered and asked questions intelligently. He had severe pain during the night, and received two doses of morphia. Stimulants were given, but at quarter to nine he died. No eruption could be seen on face, arms or front of body.

This case is remarkable from its rapid course and sudden termination and the absence of the eruption. It would have been impossible to determine the nature of the disease if the case had been solitary; but he entered with the three others who all passed through the regular stages of the disease.

This patient was not a very robust man and had lived rather freely, but on entrance he did not seem to be much worse than the others, only complaining more of headache and backache. He seemed in no special danger.

The next case is one of mild discrete variola, and is a good example of the normal course of the disease except in the slight irregularity caused by his companion's death.

CASE II. Charles M., entered at the same time with the previous case. He had marked initial symptoms commencing at the same time. When first seen

in the afternoon of October 26th, his pulse was 114. The next day a few pimples were seen in the morning, and his pulse was 96; in the evening it was 102, and the eruption was as nearly as possible in the same condition as in the morning. The death of his companion seemed to have made a strong impression upon him, and for about twelve hours there was no advance in the appearance of the eruption as compared with the progress of another patient who came in at the same time with the disease in the same stage.

Subsequently the course of the disease was regular. He was moderately salivated; his face was swollen; the eruption was thick in places, but nowhere confluent. On November 8th he was allowed solid food, his tongue being clean, and he desiring it.

Curve I gives a very fair idea of the normal course of the temperature in mild cases. The temperature was first taken on the sixth day of the disease. It descended not quite to normal; on the eighth day the secondary fever commenced; on the thirteenth day there was a remission which coincided with the commencement of desiccation. On the eighteenth and nineteenth days was an elevation corresponding with the period of desquamation. There was a temporary rise on the thirty-first day, undoubtedly due to headache and pain in the bowels following exposure at an open window with insufficient clothing.

The next case was one of the severest which recovered.

CASE III. John S. M., age twenty-seven, brother to Charles M., plasterer, not vaccinated, entered at the same time with the two previous patients. He first felt sick October 22d, with the usual symptoms. On entrance the tongue was moist, slightly furred; there were pimples and perhaps vesicles on the face, pustules on the hands. The eruption was not then confluent, but very thick. There were a few pustules on the palate. Pulse 100.

He passed a restless night. The next day the eruption was thicker on his face; the pulse had fallen to 78. He was less unfavorably affected by the death of the first case than either of the other two who entered at the same time. His eyes troubled him and his throat was sore; his face swelled so as to close his eyes. On the eighth day of the disease the secondary fever began. On the tenth day it is recorded that he had been slightly delirious at night, and began then to be so in the daytime. On the eleventh day his tongue was dry and slightly dark-colored; pulse 102. The symptoms became more serious; the typhoid condition of the tongue increased, and it could not be protruded beyond the teeth. Subcutis tendinum ap-

¹ The cases on which these observations are founded were under my care in the winter of 1869-70 at the Boston Small-pox Hospital. They formed the basis of a paper which was read before the Medical Observation Society, but has never been published. Much of that paper is here reproduced.

² Bericht über das Auftreten der Pocken im Jacobs Hospital zu Leipzig und Beobachtungen über die kleinen Pocken-Epidemie, Dasselbst im Jahre 1864. Von Dr. Robert Richard Leo. Archiv der Heilkunde, Heft 6, 1864.

peared; chills were frequent; the countenance became dusky. The eruption had become confluent over nearly the whole of the face, but was less abundant on the limbs. On the thirteenth day the pulse was 96, and the delirium continued during the day, though he knew me. He then became noisy and talkative; his hands trembled very much. During the night of the fifteenth day he had a spasm, cried out, kicked, bent his head back by jerks and drew himself down to the foot of the bed; he then fell asleep. The next night he had only one spasm, and that not so severe as on the previous night. He slept more and was less delirious.

While he was the sickest he had nearly a quart of rum in the twenty-four hours; this was reduced as soon as he showed signs of improvement. The eruption gradually dried up, and on the nineteenth day his face was clearing up.

CASE IV. A. B. P., age twenty-three, said he had been vaccinated but it did not "take" well. He did not enter till after the initial fever had subsided. The temperature rose until the twelfth day, when it reached 105.4°. On the fourteenth day a pint of rum was given during the night, and the temperature fell to 101°. Afterwards the influence of a previous malarial poisoning may have shown itself in the high elevation of the temperature every second day.

CASE V. N. R. T., bookkeeper, assisted in the care of his brother, who had small-pox. On the 4th of December his brother was attacked, and on the 11th he was vaccinated. On the 18th he felt the first symptom of the disease, seven days after the vaccination and fourteen days after his brother was taken sick.

On his entrance to the hospital the vaccine scabs were large, dried up, surrounded with an areola about three sixteenths of an inch wide. The initial fever seems to have been moderate, the eruption first appeared three days after the commencement of the disease. On entrance there was a scattered eruption of vesicles on the forehead, face and arms. One pustule was on the conjunctiva.

The disease pursued a regular course until the thirteenth day when the pustules changed their character and formed large blisters partly filled with thin, pale-colored serum. He became delirious, the tongue was dry, there was a typhoidal condition, he passed urine in bed, respiration became labored and irregular; on the sixteenth day he died, having convulsions just before death. After his death I learned that he had a succession of severe chills on the thirteenth day. After death the skin became very yellow. He died from pyæmia due to absorption of the pus from the pustules.

The vaccination was performed from five to seven days after the exposure. Though there was an interval of seven days between the vaccination and the commencement of the disease the course of the latter was not modified; he had variola vera. When first seen the vaccine disease appeared nearly normal; if any difference, there was a dryer scab than would have been expected and perhaps more areola.

The next case, of varioloid, shows the contrast between that and variola in the course of the temperature. The case is also of interest on account of the exactness with which the period of incubation is defined.

CASE VI. A. G. W. C., age twenty-two, entered December 3d. He said that he had been vaccinated, and shows two small scars on the left arm, which would generally be considered as of doubtful efficacy. The day before Thanksgiving, November 17th, he stood up in the cars by the side of a man covered with the scabs of small-pox, some of which were dropping off. November 27th he felt a little feverish and on going to bed he took a warm bath. At night, November 29th, he had one or two spots and the next morning more. On entering he had pustules scattered over his face, limbs and body, they were fully developed, some were umbilicated. The temperature on entrance and that evening was high, perhaps on account of his wandering about and getting somewhat excited about finding the hospital.

There was no secondary fever, the temperature steadily falling from the time he entered the hospital.

The period of incubation in this case was only ten days. The eruption appeared two days after the beginning of the disease.

The next case is one of hæmorrhagic small-pox.

CASE VII. Bridget G., age twenty-three, servant, not vaccinated, entered February 8th, was first seen on the 9th. She was taken sick on the 2d, about 11 P. M. The next day she felt better and went to work; at noon she took to her bed with headache, backache, chills and fever. The eruption came out on the fourth. She said she vomited all the time until something was given her which checked it. Her sister said the vomitus was dark.

When seen her mouth was covered with dried blood and sordes, the gums were swollen, tongue dry, gums bled easily. After entrance she vomited about three quarts of a black liquid and passed the same at stool. The face, neck and arms were thickly, and body and legs sparsely, covered with eruption. The catamenia were present, or there was hæmorrhage from the vagina. Pulse was 90, very weak. Aromatic sulphu-

ric acid checked the vomiting and she passed only a little more blood by stool.

February 11th she continued about the same without vomiting but restless until quarter-past eight in the morning when she bled from the mouth and the urine was bloody. About an hour later she died. About two hours before death the eruption began to turn purple and about half an hour before death this became still more marked.

CASE VIII. John T., age thirty-three, laborer, vaccinated, had a rather high fever with a thick eruption, face much congested and swollen. He presented every appearance to lead one to think that he would have the fully-developed disease; but on the ninth day the pustules on the hands were reduced to small red spots with a small crust in the centre; the temperature was low, pulse 66. An alveolar abscess sent the temperature up for two or three days.

CASE IX. Thomas J. H., age twenty-three, was singular only in having symmetrical groups of nearly or quite confluent pustules on the front of the upper part of each thigh, over each instep, and on the median line over the trachea. Each group was situated in a space almost entirely free from other pustules. The course of the temperature was normal, showing, however, rather exaggerated morning and evening remissions and exacerbations during the secondary fever. Exacerbations on the evenings of the eighteenth, twenty-first and twenty-fourth days are not explained, unless he had small abscesses which he concealed, or unless it be due to the character of the eruption which marked this case as belonging to the corymbosae variety.

Dr. Mason in "Reynold's System of Medicine," describes variola corymbosa as rather rare, and a very fatal variety, giving a mortality of 44 per cent. among the unvaccinated, and of 32 per cent. among the vaccinated.

This patient said that he had been vaccinated, but I could find no scars. This was the only case in which the eruption was thus grouped. On the twenty-seventh day he was discharged.

CASE X. L. S., age twenty-five, not vaccinated, was confined with her first child (illegitimate) about two weeks before this sickness. The eruption appeared not quite two days after the first symptoms. She flowed considerably, and had a cough which increased the flow. On the eighth day the eruption became hæmorrhagic, and she died the next day.

CASE XI. Henry C., age thirty-two, had not been vaccinated. He had led rather a dissipated life, and had been in the habit of taking liquor. On February 14th he had pain in back, headache, pretty severe chills, vomited. The eruption came out on the 18th. He entered the hospital on the 19th. He became delirious, so that for three days the temperature was not taken. He became so violent that it was necessary to secure him in bed.

February 24th he had become calm, and during the next week he seemed the same as other patients, except that he had delirium, with trembling, saw large dogs at the foot of his bed, thought he was to be led out to be shot, etc. His temperature was high, his pulse low.

March 1st a few blisters appeared on his legs, which seemed to be formed by the loosening of the cuticle between several pustules. He continued to do well, and took food well until the night between the third and fourth of March. He was again delirious, the temperature rose, and the delirium became of a low, muttering character, with constant picking at the bed-clothes and fingers. It was learned that the attendant had given him articles of food which had not been ordered; more care was taken as to diet, and in two days he was over the delirium.

He had severe abscesses, and a large amount of pus

* Temperatures not taken on account of delirium

collected in the calf and instep, which was evacuated, and fifty days after admission he was discharged well.

Delirium tremens was, in this case, an unfavorable condition. It is not specially mentioned by authors, though it is said that the intemperate are very likely to die. The increase of delirium on the fourth of March was due to the error in diet, but at the time it seemed as though the patient was doomed to die. Probably the inflammation in the leg was also an element in causing the delirium.

The next case gives a very characteristic temperature curve, and the patient was very sick; the prospect for a few days was not favorable, but he recovered finally.

(To be continued.)

DIGESTIVE PARESIS.¹

BY E. N. WHITTIER, M.D.

I offer the term as a composite of the group of functional disorders, of which diminished peristalsis, lessened secretion and delayed digestion are important and representative members. Impaired power is a constant factor in each of these processes.

The muscular tissues of the digestive tube fail to exert their normal influence in the propulsion of ingesta from causes so complex as to elude the careful study of the physiologist in his efforts to determine the underlying, controlling and controllable condition.

We are told that the nervous mechanism of stomachic peristalsis is very obscure: that the quantity of the contents of the stomach is a prime factor in provoking peristalsis; that in the intestine quantity soon ceases to be causative; and that intestinal peristalsis may occur wholly independently of the central nervous system.

It is for the general practitioner not to reason why, but to recognize clearly and to accept as conclusive the doctrine of the important part played in the melancholy drama of digestive disorders by diminution of peristaltic power.

In our study of the deviations from normal digestion induced by changes in the character or in the quantity of the digestive fluids, we find but little to aid or comfort us in the "Theory of Secretion" as set forth by the physiologist; for the stomachic and intestinal secretions—gastric, hepatic, pancreatic and succus-entericus—are paraded as maintaining a struggle mutually destructive—a kind of eternal internal and intestinal vendetta. We are told that pepsin in an acid solution destroys the active constituents of the saliva and of the pancreatic juice, and in its turn is antagonized or destroyed by the bile and the other alkaline juices of the intestines.

Both diminished peristalsis and lessened secretion of digestive fluids, sustain an important causal relation to delayed digestion; it is pre-eminently a result, in the production of which these processes are prime factors, and it is during this delay, induced by impairment of the power needful for the proper performance of digestion, that the major portion of those changes take place in the ingesta, which give rise to the phenomena calling for remedy at our hands.

Delayed digestion is a symptom-complex, into which neuroses disorders, functional and organic, depraved blood states, circulatory derangements of the heart and abdominal viscera enter, and in turn are made worse. Action and re-action in this condition are well-nigh equal; the baneful influence of this process extend to all parts of the body, whose various members conspire to return with interest the unwelcome debt of discomfort.

No condition is more pitiable than that of the chronic dyspeptic. No disorder has a larger following than functional dyspepsia. No class of cases is more vexatious alike to the patient and the physician. The victims of this malady, in ceaseless tramp, vex the corridors of our dispensaries and hospitals, or in melancholy round complete the circuit of our offices.

The general practitioner finds the information gained from careful study of the literature of this subject, inadequate to the task of successful treatment of these

disorders. Good knowledge of what is known of the physiology of digestion and of the functional causes of departures from normal results, is insufficient; it must be complemented by sound judgment and ripe experience, and by a personal influence powerful to control the psychical disturbances which sway the patient from hope to despair, and alternate courage with fear; but, control once induced, it secures the most important contribution to the patient's welfare that can be made, for by no other method can the physician accomplish more satisfactorily the desired object of placing the patient in a position where

"Good digestion wait on appetite,
And health on both."

Prof. Edward H. Clarke, whose portrait-bust adorns this hall, was one of the leading therapists of his day. He combined in largest degree close accurate observation and sound reasoning, essential prerequisites to high attainments in this branch of our art.

No man ever listened to the glowing words with which he clothed his argument on the personal influence of the physician, an argument in which he placed highest and first in the list of remedial agents, the personality of the practitioner, without being convinced of the truth of the words (in which sound logic was combined with sincerity) wherein he presented the therapeutic questions involved in the treatment of the class of disorders of which my subject is a prominent type.

I am not an advocate of the schedule diet system. No man may start the digestive train for a through trip on the main line, with good expectation of making all the connections, and reaching the terminal station free from delays, derangements and derailments. The pneumatic-block system on the intestinal track works harm and not protection. Dietetic rules, formulas and carefully prepared combinations are scheduled for our guidance, and in general they may be said to be right; in many essential particulars it must be conceded that they are too frequently wrong. The situation has not been materially changed since Lucretius (95 B. C.) wrote:

"Quod ali cibus est
Alis fuit acre venenum,"

paraphrased later by Beaumont and Fletcher,

"What's one man's poison, Signor,
Is another's meat or drink."

There are but few conditions in which the patient is more dependent for a good result upon the experience and judgment of the physician; for example, when to employ and when to discard milk; when to diminish or when to abolish starches; when proteids should predominate or be omitted altogether, with the wide range of modifications, combinations and interchanges. One thing I have learned full well, that it is fruitless to oppose the well-grounded convictions of chronic dyspeptics, the result of their experience in following a dietary based upon text-book schedules formulated from processes which are physiological and normal; we must look to other sources for the rules which shall govern our efforts to secure control over functional digestive derangements of the stomach, but more particularly of the intestinal canal.

Changes in the ingesta, effected by digestive secretions, have been carefully reported, in the earlier instance of Alexis St. Martin, by Surgeon Beaumont, U. S. A., and in the more recent (1891) tabulations of MacFayden, Nenckle and Sieber, whose case of an

¹ Read before the Boston Society for Medical Improvement, February 26, 1894.

ileo-cæcal fistula in a woman afforded the unique opportunity of determining changes wrought by the combined effects of all the digestive fluids. The deductions of these observers have been ably supplemented by painstaking experiments carried out in physiological laboratories.

But it must be conceded that these conclusions based upon normal conditions and normal results, sustain unimportant relations, so far as treatment goes, to the abnormal processes which characterize digestive disorders as a class.

A practice which obtains too often, and perpetuates an error which is pernicious, is that of treating these disorders as if the fault was primarily in the digestive apparatus, and independent of the general condition of the patient. Until such views cease to exert their baneful influence, digestive-paretic states must take their chance in common with other frequently misunderstood self-limited disorders, and the lack of success by treatment will continue to be an abiding reproach.

The physician should endeavor not only to attract the patient away from the easily acquired habit of introspection and self-condemnation, and from the "enjoyment of poor health," but he should also and at the same time strive to energize other functions than the digestive. Superficial thought, unformed judgment, or insufficient experience prompts some to overlook the primary and fundamental cause, and to concentrate time and treatment on this only, one of the many symptoms of a depraved general condition.

With your permission, Mr. President, I will depart from the further consideration of this branch of my topic for the purpose of considering the causes and the conditions which have brought into so great prominence the modern method of treating functional digestive trouble. We may not readily discover the explanation for this centring of treatment. The opinion, that it is possible to secure and to maintain internal antisepsis, is strongest in commercial circles; it is a bad day for samples, and for the hoarder thereof when some new synthetical compound or novel coal-tar product is not obtruded during our office-hours. The effort to determine a method by which fermentations in the digestive tube shall be limited, occupies a prominent place in bacterio-physiological work, but as yet no man has succeeded in doing for the physician and internal antiseptis, anything in any degree corresponding to the glorious work accomplished for the surgeon and external antiseptis.

I can find no good evidence of any material advance towards medical antiseptis during the past five years, neither in the literature of the subject nor in the opinion of bacteriologists whom it has been my privilege to consult; and I cannot obtain much promise for the immediate future.

Our distinguished associate, Dr. McCollom, assures me, that although the fulminating power of the bacillus coli communis, when discharged into the peritoneal cavity, notably in cases of perforating appendicitis, has been demonstrated by the results of laboratory work, but little knowledge has been gained of the bacteriology of the digestive anomalies classified as functional.

In spite of the disappointment arising from lack of success in bacteriological efforts to give us controlling knowledge of bacterial processes during digestive disturbances we cannot fail to notice the claims to recent advances in applied therapeutics.

The empiricism of the mercurialist of earlier days

has given place to accurate knowledge of the antiseptic properties of the mild chloride, leading some of its votaries to assign it as prominent a position, as an internal remedy, as that occupied by the stronger chloride in surgical practice externally.

The advocates of quinine as an antithermic, have changed their views since the experiments of Eberth demonstrated so conclusively its power to check the growth of the bacillus typhosus, and his deductions are in keeping with those of Bouchard, to the effect that quinine as an antiseptic holds a higher position than quinine as an antithermic, that reduction of temperature is the result of the arrest of the bacillary development in the intestinal canal and the result of the destruction of toxins in the blood.

We may not reasonably expect any considerable return to the heroic and discomforting doses of quinine in the treatment of diseases of the intestinal canal, not because of any inherent defect in the action of the drug, nor because of any unsoundness in the conclusions formulated, as cited, but because of the lessened inconvenience and the greater precision which now obtains in antiseptic medication by the exhibition of the modern synthetical compounds and notably by the derivatives of the coal-tar series.

Professor Henry describes the difference between antiseptic medicine and antiseptic surgery, as of degree rather than of kind: that surgical antiseptis is so precise that it may almost be counted among the exact sciences; that while antiseptis in surgery is a preventive of the absorption of toxins from a pathological surface, it is subject to limitations in medical practice, because in many instances the processes contended with are in no essential degree departures from physiological; that disinfection within the body is not a simple, but a complex process, in which the agents employed may produce their effect but only after having run the gauntlet of the stomacic and intestinal secretions, exposed to the contingencies of destructive changes immediate and direct, and to the modifications incident to absorption and excretion, in the hope of correcting errors, whose local causative conditions have not yet with sufficient accuracy been defined, a form of a sub-way motor process, "running wild" in the dark, on an unfamiliar track.

Modern medical appliances have given us free access to the stomach and large intestine. Kussmaul and his ardent followers have demonstrated the efficiency of the means employed for the control of fermentative changes in acute and chronic gastric disorders; the ease with which the colon may be flushed, and the comparative safety with which its contents may be rendered relatively aseptic are too well understood to call for remark.

We have, therefore, left for our consideration those measures and those remedies which address themselves to checking the development of micro-organisms in the inaccessible portions of the digestive tube.

Fermentative and putrefactive bacteria cannot be isolated from the contents of the small intestine: even in disorders of function, they abound in numbers and in degree of activity exceeding computation; this, too, in spite of the hitherto accepted "antiseptic property of the bile," which Nencke has demonstrated to have little or nothing of such influence. Bacteriology has proven beyond all doubt the part played by micro-organisms in the origin, development and course of infectious diseases. But until recently it has been suc-

cessfully maintained that the arduous labors of the bacteriologist were without practical results, that disinfection within the body could not be secured, that the disease-producing germs could not be killed, that their growth could not be hindered, that the power of various pathogenic micro-organisms to produce toxins could not be overcome and that once produced the various toxic products could neither be antagonized nor destroyed; but we have great reason for concluding that the situation has been changed, and that the hope expressed by the earlier observers (that some plan of treatment would be devised whereby fermentation and putrefactive changes in the contents of the small intestine would be arrested) has been in considerable degree realized.

The subject of internal antiseptics or disinfection within the living body has, as one of its most prominent chapters, intestinal antiseptics. The literature on this particular topic is voluminous, comprehensive and of large practical value, and the conclusions formulated by the more recent authorities are of deep significance.

The therapeutic problem, to administer such remedies as will supplement the defect in the results of nature's antiseptic efforts, is rapidly progressing towards solution. It still ranks as the foremost therapeutical question of our time, ably set forth as such by Professor Henry in his paper read before the Association of American Physicians in 1891.

Therapeutic intervention is needed in all the cases which correspond in origin and in effect with that of the subject I have the honor to present for your consideration and discussion, and those remedies that promote intestinal antiseptics, with the least danger to the individual, are deservedly assigned prominent positions in the pharmaceutical preparations of the day.

But it is not so much an admission of inefficiency in the modern remedies to induce internal antiseptics, as it is evidence of the more careful study of the many contributing causes of intestinal putridity, that more rigid dietetic rules are now insisted upon; nor do we confess essential defects in the power of the remedies employed to promote intestinal antiseptics, when we insist upon more rigid observance of the rules favoring elimination of the toxins formed within the body, but because the important part played by the skin, the respiratory surfaces and notably the kidneys is now more highly appreciated.

To Selmi, who in 1872 isolated from the products of putrefaction the poisonous alkaloids to which he gave the name of ptomaines, and to Semmola, who but little later instituted a method of treatment designed to destroy the toxic substances developed during the progress of diseases of the intestinal canal, should be given the honor of having been the first to deal intelligently with the great principles of intestinal antiseptics. The aid of chemistry has been invoked in the preparation of remedies which evade the solvent properties of the salivary and the gastric secretions, and remain unchanged until they reach the intestinal fluids, where they discharge themselves of their duty, only as they are split up into their soluble component parts. It is this peculiarity which confers upon the intestinal antiseptics the powers claimed for them by the manufacturers and their gentlemanly representatives. Take, for instance, salol; it is this property of cohesion, until the remedy has found its way into the small intestine, of disintegration as soon as it meets the intestinal fluids, which confers upon it

its high reputation as an intestinal antiseptic. Naphthalin, hydro-naphthol and A and B naphthols belong to the same class, and in combination with salicylate of bismuth have gained prominence; but in spite of the somewhat encouraging contributions to our knowledge of the therapeutics of the naphthol groups, objections to all the members of this series exist to a considerable extent, and are entitled to careful consideration, for these objections are based upon difficulties of administration, of stomachic disturbances following the exhibition of this class of remedies, upon the apprehension that changes in the color of the urine to dark brown and green, as well as painful micturition, are evidences of irritation of the urinary organs, possibly harmful, and because there is ground for fearing that we are not yet sufficiently well informed as to the varying and inconstant degree of toxicity residing in naphthalin, hydro-naphthol and the naphthols A and B.

Enumeration of new combinations might be definitely and unprofitably prolonged. The latest remedies, to the description of whose virtues pamphlets are devoted, are not of necessity the best. The recent eruption of five of the naphthol-phenol-bismuth series in one circular may be accepted as evidence of effort on the part of dealers to satisfy a demand as yet unsatisfied for a safe, reliable and efficacious intestinal antiseptic.

The most recent plans proposed for the local treatment of disorders of the digestive tube, include methods by which there shall be secured for the patient the largest possible freedom from the influence of the micro-organisms and their products, and these plans will be found to be based upon rules which are the outgrowth of bacteriological research and attainments in other directions than that of the subject under consideration; and still further, bacteriological logistics may be relied upon for the correctness of the conclusion that at no distant day concrete examples will be shown demonstrating our control over the major portion of the acute and chronic disorders of the intestinal canal.

Prominent among these plans will be found:

- (1) Measures to favor elimination, notably of the toxins.
- (2) Dietetic rules by which the opportunities for putrefactive changes in the digestive tube shall be lessened.
- (3) Antiseptic medications, or the use of the more recent internal antiseptics, by which better and more than formerly the contents of the small intestine shall be, so far as profitable, sterilized.

While I may claim, with reference to this branch of my subject, that the limitations of bacteriological therapeutics are so pronounced that, in spite of greatly increased etiological knowledge, our power of successfully treating intestinal digestive disorders has not been materially advanced, and that we may, at least, render the verdict "not proven," I am inclined to yield somewhat these pessimistic views, and for the sake of argument, side with the optimist, who considers it providential that such views cannot and do not prevail, and do not control treatment; for he believes that disinfection within the living body has entered upon a career, comprehensive, progressive and well-nigh limitless; he cares but little whether the power to disinfect is exercised directly upon the micro-organisms, upon their toxic products, or because it imparts to the cells of the body an increased power of resistance to toxins. All this is immaterial, for in his opinion the

demonstration is complete, that immunity to a degree hitherto unexpected, and even now with difficulty realized, has already been induced. To him, earnest workers in the physiological and bacteriological laboratories of this and of other countries, present in their carefully-drawn conclusions, arguments of great weight and power, competent to convince the most sceptical, to the effect that preventive medicine has entered upon a new era, a reign of control over disease, wider, deeper and more beneficent in its influence for good, abounding in larger promise of blessing for the sick and suffering than at any period in the history of mankind.

COMPOUND FRACTURES.¹

A STUDY OF THREE HUNDRED CASES.

BY J. G. MUMFORD, M.D.

In reading the articles on compound fractures published during the past five years I have been impressed by the fact that the writers have striven to demonstrate the advantages of certain methods of treatment, and that their short and favorable lists have furnished no proper data for the general consideration of such formidable injuries. To cite a single instance: Mr. Treves, in the *Annals of Surgery* for February, 1893, gives a list of 61 cases, with one death. As this article fails to define the character of the fractures, further than to state that they are of the leg, and aims only at lauding a particular method of treatment, but little can be concluded from it. Other authors deal with the subject in connection only with their treatment of some special fracture or group of fractures, so that the practitioner or student must be often in the dark as to the general characteristics of these lesions.

A year ago I published a paper classifying and analyzing fractures of the skull. In the present essay, therefore, I shall omit the consideration of head injuries, excepting only fractures of the maxillary bones.

It is difficult in an article of this kind to properly limit one's self. A serious railway crush of both femora or of the pelvis, should be ruled out as essentially fatal. A similar crush of one arm or leg should be ruled out when it calls unquestionably for amputation. I shall not consider fractures in the feet and hands, as they are too complicated in their nature, do not in these days seriously endanger life, and nearly always heal up soundly, or call for immediate amputation.

There is a variety of fractures of which I have attempted to treat as conservatively as possible, but which is often hard to classify. Thus, twenty years ago a badly comminuted and lacerated leg would have been amputated. It would not then have come under the head of the injuries I am dealing with. Ten years ago a similar leg would have been amputated by some surgeons and saved by others. To-day we should all save it. To-day, therefore, it is a compound fracture in the sense in which I use the term. But there are fractures seen to-day as to which the question, to amputate or not to amputate, rises. If we amputate, we do not count this case in our list as a compound fracture. If we save the limb by a miracle, we consider the case a clever piece of conservative surgery.

In making up this list, therefore, I have not been able to take into account differences or errors in judg-

ment, and have had to divide this class into cases essentially hopeless and those presumably hopeful. It is under the head of those presumably hopeful that we come subsequently upon our cases of secondary amputation. I shall deal with fractures of the long bones of the extremities, the jaws, the scapula, and the patella, omitting all such cases as are, in the light of to-day, essentially fatal or which call obviously for immediate amputation.

The mortality from compound fractures is high; that of certain bones very high. The general mortality is higher than that from typhoid, pneumonia and certain other acute infectious diseases. The public, certainly, and many physicians, I think, underestimate the gravity of these lesions.

To get at a fair, and, at the same time, a favorable estimate on the subject I have analyzed 300 consecutive cases taken from the Massachusetts General Hospital records for the past eight years.

Out of a total of 300, 270 recovered and 30 died, a mortality of 10 per cent. There were but 9 women and 291 men. One woman died. The following table gives the relative frequency of the fractures:

	Cases.	Died.	Mortality.
Tibia and fibula (both)	111	10	9.009%
Tibia	53	7	13.2
Humerus	33	1	3.33
Femur	25	7	28
Radius and ulna (both)	20	2	10
Inferior maxilla	14	0	0
Patella	9	0	0
Humerus, radius and ulna (elbow joint)	8	1	12.5
Radius	8	1	12.5
Fibula	7	1	14.28
Olecranon (distinguished from ulna)	4	0	0
Ulna	3	0	0
Humerus and ulna (both)	2	0	0
Femur and tibia	1	0	0
Scapula	1	0	0
Superior maxilla	1	0	0
Totals	300	30	10%

From this list it will be seen that 37 per cent. of all the fractures are those of the tibia and fibula together; 17.6 per cent. are of the tibia alone, and 2.33 per cent. of the fibula alone. Practically, fractures of the leg constitute 57 per cent. of all the compound fractures in this list. The forearm comes next with 11.6 per cent., the humerus with 11 per cent., and the femur with 8.33 per cent., the lower jaw with 4.66 per cent., and the patella with three per cent. The other fractures—those of the scapula, upper jaw and unusual joint complications—are so rare that they may be classed as surgical curiosities, and together make up less than 5 per cent. of all the compound fractures. I have purposely omitted from the list fractures of the nose, as they were seen only in the out-patient department and could not be properly followed up.

Since these cases are taken as they occur in routine practice and are not selected for purposes of treatment demonstration, as they are seen by a number of different surgeons, but follow a regular routine of treatment, I will sketch out briefly the method of the management, when uncomplicated.

With rare exceptions ether is given in all cases of compound fracture.

In the reduction of fractures of the leg no unusual plan is followed. Some years ago division of the tendo-Achillis was thought to be of advantage when there was great over-riding of fragments, but experience showed this manœuvre to be of questionable advantage. The usual shaving, scrubbing, syringing and

¹ Read before the Boston Society for Medical Improvement, February 26, 1904.

general disinfecting of the limb have been thoroughly carried out for many years. Chlorinated soda, sulpho-naphthol and bichloride are the favorite washes used. The leg is then put upon a Cabot splint and dressed. This splint is a simple wire frame, made from a single piece and bent so as to fit the ankle and knee. The wound is dressed, simple wooden side-splints are put on to prevent lateral bowing, and the apparatus is bandaged above and below the site of the fracture. An unenclosed area is left open for the renewal of the dressings.

The only variation in this style of treatment for many years has been in the first dressing of the compound opening. Up to 1891 it was the almost invariable custom to establish the freest kind of drainage. If necessary, to enlarge the wound; usually to make counter-openings, as dependent as possible. Stitches were rarely taken, and a primary union was seldom expected. Within the past three years drainage has become much more infrequent, for reasons which I shall subsequently discuss; and stitching, with primary union, has been common. Plaster as a first dressing has been rare. After the wound has become simple, however, the limb has been put up in a plaster splint and the patient given crutches. The method of treatment by these posterior wire- and side-splints has long been deservedly popular with those accustomed to their use. The splints are light, simple, easily kept clean, readily applied, quickly changed, and provide most conveniently for secondary dressings without disturbing the limb.

Fractures of the thigh are put up in an extension apparatus of some kind—the long Dessault or the Bucks—with a posterior and long outside splint, conveniently arranged for proper dressing of the wound.

The patella fracture is put on a posterior splint, with coaptation splints to control the quadriceps femoris.

Fractures of the upper extremities are put up in a variety of apparatus, consisting usually of shoulder cap, coaptation splints, internal angular at the elbow, and anterior and posterior splints for the forearm.

It is not my object in such a paper as this to discuss the relative merits of the various apparatus devised for these injuries. So long as the fragments of a bone are securely immobilized, with due regard to the patient's comfort, it is of small moment what the style of apparatus may be. I am most decidedly of opinion, however, that proper provision should always be made for subsequent dressings and care of the wound *in situ*.

Fifty per cent. of these 300 fractures were due to crushes, and a large majority of these crushes were sustained in railway accidents. I have previously called attention to the extremely serious nature of these accidents. A description of the results of such crushes and of the pathological conditions ensuing is given by Dr. Alexander Ogston, of Aberdeen, in the *Medical Chronicle* for November, 1888. The bones in these cases are nearly always comminuted, the soft parts are severely lacerated, and there is frequently a resulting bone necrosis. Of these 151 cases of crush, 102 were comminuted and lacerated, with a resulting necrosis in 26. Twenty-one of the total 30 deaths followed crushes; so that we may say that the mortality after crushed fractures is 13.9 per cent. I do not, of course, include those cases which are essentially fatal.

Fractures from horse-kicks I have put in a special class. This may be fanciful, but I find that in

these cases comminution is very common, primary union rare and long suppuration frequent. There were 24 of these cases, with a mortality of 4.16 per cent. Of other fractures, from blows there were 27, with a mortality of 7.4 per cent.

Next to crushing accidents the most common cause of a compound fracture is a fall. Of these there were 100, with a mortality of 6 per cent. It would appear from a study of the tables that fractures from this cause are the least severe of all, and the prognosis good. The violence is indirect, comminution uncommon and laceration slight. Here we may stitch with a good prospect of primary union, and usually without drainage.

Four cases of bone necrosis and 13 of comminutions are divided between the classes of blows and falls.

In the whole list, though, I found bone necrosis recorded less often than I should have expected. It occurred 30 times, a proportion of 1 in 10. One of these died of prolonged suppuration, after two operations for the removal of sequestra. Twenty-one cases in all required these secondary operations. The longest in healing after the primary accident was twenty-four months, the shortest was three months.

In a carefully treated hospital case *ununited fracture* is a great rarity. The reason probably is that the rigid hospital discipline, the admirable dietary and good hygienic surroundings, favor proper and rapid union. Many cases of non-union which I have seen in private practice were directly traceable to the negligence of the patient himself.

In my hospital list there are records of but seven ununited fractures: Four of the humerus, two of the radius and ulna, and one of the femur, all were eventually wired, and recovery ensued.

Fractures with joint complications were found to be quite common in the list, but the mortality during the past three years has been surprisingly low, and useful joints have frequently resulted.

Joint.	Totals.	Excised.	Ankyloid.	Died.	Motion.
Knee	13	0	9	1	3
Shoulder	1	1	0	0	1
Ankle	9	1	5	1	3
Elbow	26	7	6	0	20
Wrist	1 (gangrene, amp. 3d day)			1	0
Totals	50	9	20	3	27

The total number of joints involved is seen to be 50, with 3 deaths, a mortality in joint fractures of 6 per cent., a lower mortality than the total average of 10 per cent. The fact that prompt and thorough excisions were done in nearly all desperate elbow fractures, which include a majority of all the joint fractures, accounts partially for this low mortality. In the elbow fractures which are amenable to more conservative treatment it is gratifying to see how, in recent years, a recovery of function has followed thorough antiseptic treatment without excision. There were 19 elbow fractures not excised, 13 of these cases recovered with good movable joints. Several of the 6 ankylosed cases were directed to return for subsequent resection, but their records I have been unable to trace. Most of them probably preferred to remain as they were, with the elbow at a right angle.

That 9 out of 13 knee-joint fractures remained ankylosed must be considered a good result relatively. Three recovered with motion, and but one died. It is a fair presumption that more of the cases would have recovered with motion, had they persisted in the use

of passive movements—a manoeuvre so difficult to properly carry out with hospital patients.

Of the 7 elbow resections it should be said that 3 were primary and 4 were secondary, or after the third day, when it became evident that a useful joint could not be saved. They all recovered well, the average length of convalescence being six weeks.

The one ankle-joint excision was secondary, in a middle-aged alcoholic subject, after two months of suppuration. He recovered with a fairly useful false joint.

There was one primary excision of the head of the humerus, with a satisfactory joint resulting.

Aside from the joint excisions the humerus was resected twice, and the bones of the forearm once. A total of 12 resections with excellent results in all.

Primary wiring of bone was done 27 times. Twenty of the cases got good union, and 7 had necrosis. It is noticeable that these 7 cases of necrosis were treated by the open method, that is, the wound was left unsutured and the wires extruding.

One of the cases of compound ankle-joint was complicated by laceration of tendons. The tendon of the extensor proprius pollicis was sutured, and good union followed. The man recovered with a movable joint.

As was said at the beginning of this paper, those cases of compound fracture are excluded which are essentially fatal. The question immediately rises, What cases are these? I admit at once that such a question cannot be accurately answered, but that the decision must be left to the individual surgeon. A vast number of very serious injuries are in these days survived, in a manner which would have astonished our fathers, so that we have come to regard hopefully the most grave and extensive lesions. Prosperous looking cases do occasionally die, however. I have found in this list six causes of death. They are: sepsis, shock, delirium tremens, fat embolism, gangrene (as distinguished from the ordinary suppurative processes), and nephritis.

Sepsis does not appear to have decreased materially within the past eight years. There were 20 cases with 10 deaths; a total mortality from sepsis of 3.33 per cent. In 1885 there were 4 cases; in 1886, 2 cases; in 1887, 2 cases; in 1888, 2 cases; in 1889, 3 cases; in 1890, 3 cases; in 1891, 1 case; in 1892, 1 case; in 1893, 2 cases. Secondary amputation was done in 3 of these with 1 fatal result; 7 died of septicaemia, and 3 of pyæmia. There were 3 cases of erysipelas, all of which recovered.

Of course, all of these septic cases received the most thorough antiseptic treatment; the favorite local application being baths or constant irrigation with bichloride or sulpho-naphthol.

The age of the patient in sepsis seems to have had no bearing on the result. Those who died ranged from nineteen years to sixty-five years. There were among them 3 fractured femora, 6 fractures of the leg and 1 of the radius.

The nature of shock and collapse is still so uncertain that it is difficult to distinguish them always from other conditions, notably embolism. Those cases which entered the hospital and died within twelve hours I have included in the list of essentially fatal cases. There were 15 cases besides these which fell into a condition of shock subsequently, the effect of operation, ether or secondary hæmorrhage; 8 such cases survived and 7 died.

There were not many recorded cases of delirium

tremens: 9 in all, and 6 of these died. The deaths were obviously due to delirium tremens. It happened that none of the injuries were especially severe. The injuries of the three survivors were as bad as any, but the men averaged much younger. It is recorded of one that he was cured of drinking, and a year after his discharge was a total abstainer. Contrasted with him was an individual who gave his name as Yale College. He was a negro. His injuries were comparatively trivial; but he died on the tenth day, after a week of delirium.

There are 8 recorded cases of fat embolism, with death and autopsy. All of them were due to extensive crushing of the leg.

One man died of an acute, presumably septic, nephritis, which certainly was not present when he entered the hospital; and three died of gangrene for which secondary amputations had been done fruitlessly.

	Recov'd.	Died.	Mortality of Total Fracs.	Totals.
Sepsis	10	10	3.33%	20
Shock	8	7	2.33	15
Delirium tremens	3	6	2	9
Fat embolism	0	3	1	3
Gangrene	7	3	1	10
Nephritis	11	1	33	12

Deaths 30 (10%).

Some of the cases of gangrene were most unexpected. One boy with a simple crack through the tibia, no apparent complications and excellent circulation in the foot on entrance, developed gangrene, and died three days after an amputation.

Secondary amputations were not common, however. There were but 20 in all: 7 of the humerus, 5 of the forearm and 8 of the leg.

One young man with a compound elbow eloped on the first day. He returned for amputation on the seventh day. Extensive gangrene had set in.

Of all fractures of the humerus, 21 per cent. required secondary amputation, of forearms 16 per cent., and of legs 7 per cent.

Though the figures would show that acute general sepsis is about as common now as it has been at any time within the past eight years the records prove, without question, that the general results obtained in the treatment of compound fractures are vastly better than they were eight years ago, and that within the past three years, especially, there has been most marked improvement. Local suppuration is much less common. Five years ago a certain amount of suppuration was expected; but since January, 1891, there are but 15 recorded cases. In the five previous years there were 89. In the suppurating cases recorded the mortality takes a decided jump upwards, as we should expect; 34 per cent. died.

There were a few remarkably good results as far back as 1885, when a case of fractured leg was recorded well in two months. Last year a comminuted leg was simple in one day and sound in two months, without exciting especial comment. In the same year a compound forearm became sound in six weeks.

A study of the modes of treatment employed in the last decade and in this, convinces me that the improvement in results is not due to any radical change in method. Indeed, the methods are the same so far as the sterilizing of the wound and its dressing are concerned.

Why is it then that to-day we can so frequently dis-

pense with drainage, especially with the former numerous counter-openings? In the old days that omission would have been thought madness, and when tried led almost invariably to extensive suppuration. As it is, the older charts show regularly a temperature elevated for ten days or a fortnight. Stitching the wound up tight was seldom practised five years ago. It is frequently done to-day, with a resulting primary union. Very often now, after the first dressing, the wound is left sealed for two or three weeks, when the dressing is removed and the fracture found simple. The result is that to-day a permanent plaster splint is put on within a month of the accident, and that a great many of these cases give no more trouble than do simple fractures.

The reason for this gratifying advance lies in the fact, I believe, that the environments of our surgery are clean. It has taken many years to accomplish this in an old hospital like the Massachusetts General; but the results in all branches of surgery seem to bear out the statement. Patients used to be carried into an accident-room which must have been septic, and in spite of the most scrupulous care in the management of the wound it very often became contaminated. To-day I believe that the accident-room is as clean as the abdominal ward.

In this list it will be seen that the average time of healing is rather less than stated in the standard books. Excluding such complications as humerus, radius and ulna (elbow-joint), humerus and ulna (elbow), and femur and tibia (knee), the order of the bones, arranged according to their rate of healing, is as follows:

	<i>Longest.</i>	<i>Shortest.</i>	<i>Average.</i>
Superior maxilla	1 mo.	1 mo.	1 mo.
Scapula (body)	2	2	2
Inferior maxilla	6	1	2.4
Ulna	4	2	2.5
Radius	12	1.5	3
Radius and ulna	12	1.5	3.5
Humerus	8	2	3.5
Olecranon	8	3	4.7
Tibia	24	2	4.7
Fibula	13	2	4.8
Tibia and fibula	28	2	5.6
Patella	12	4	6.6
Femur	24	3	8

Some of these averages, such as upper jaw and scapula are of little value, as they are taken from too few recorded cases. The number of these cases is significant, however, as indicating their rarity.

All the fractures of the lower jaw did well. Even with extensive comminutions there were but few necroses. Methods of treatment were diverse; but it is worthy of note that by far the best results were obtained from the use of inter-dental splints, furnished and fitted by the Dental School.

Of course, it is almost impossible to keep these fractures aseptic, and sinuses often persist until the bone is sound.

There were but 3 fractures of the ulna alone, all of which united well without any complications. The infrequency of fracture of this bone, alone, excluding fractures of the olecranon, is due to its deep position. Its fracture is almost always accompanied by fracture of the radius.

Compound fracture of the radius alone is not very common. There were 12 out of the total 300. The radius is usually fractured by falls on the wrist, and this is an unusual seat of compound fracture unless from a crush or blow. If compound, the wrist-joint is

liable to be opened. In one of the cases this resulted in death.

Both bones of the forearm are frequently the seat of compound fracture, and non-union is not uncommon. Out of 20 cases, 10 per cent. died. In treating fractures in the forearm it is not very easy to obtain immobilization except with plaster splints. As in fractures of the leg, however, primary union of the soft parts is more common than it was, and the bony unions are more rapid than they once were, the resulting callous less and good rotation more certain.

Perhaps the most difficult to treat of the ordinary compound fractures are those of the humerus. It is almost impossible to immobilize this bone in any apparatus which will admit of easy access to the wound for dressings. The practice of fastening the arm to the side and fixing the shoulder- and elbow-joints is the most practicable and common, but necessitates some movement of the arm for dressings.

From the surgeon's point of view an extension apparatus, similar to that used in thigh fractures, with the patient in bed and the arm extended at right angles is very satisfactory, but it is almost impossible to get patients to submit to such confinement.

Owing to these difficulties we find a majority of our cases of ununited fracture to be of the humerus. Secondary amputation of this bone is likewise most common. Out of 33 fractures of the humerus four resulted in non-union, as against 3 non-unions in 267 of all other fractures. Secondary amputation was done in 7 cases of the remaining 29, which leaves us but 22 cases in which good early union took place. Hence it appears that our prognosis in all these humerus cases should be very guarded. It is positively good in but 66.6 per cent., according to these statistics.

Fractures of the olecranon are interesting mainly on account of its relation to the elbow-joint, and its inefficient blood-supply. When compound, its treatment is subordinated to the question of saving the joint. It unites more slowly than the humerus, but has a lower mortality.

There is little to add to what has been already said in regard to compound fractures of the leg, except in regard to the rate of healing. As would be expected, fractures of both bones heal more slowly than those of one. The difference in rate being one month. The tibia, when fractured alone, is sound in about four and one-half months, both bones in about five and one-half months.

There is an average and fairly definite relation between the time a fracture becomes simple and the time it may be pronounced healed. If the fracture does absolutely well and there is no necrosis this relation is as one to five. If a leg is simple in one month the bones will be sound in five months. This is true, too, of the very short cases. Two cases which were simple in ten days were sound in two months. If there is necrosis and long suppuration, the ratio may be as four to five, or the bone may become sound before the wound is simple, and the figures be reversed.

It seems that certain fractures of the leg are especially liable to suppuration. All the compound Pott's fractures suppurred; and as this is the common fracture of the fibula, it will be seen that this bone when fractured alone heals more slowly than the tibia alone.

None of the patellar fractures died. Most of these were wired. Three recovered with good motion in the knee and in six there was resulting ankylosis.

As would be expected, by far the highest mortality was in fractures of the femur: 28 per cent. of the 25 cases. The great difficulty in rendering lacerations of the thigh aseptic, and the shock in these injuries, were the causes of death. Some of the cases, however, recovered with remarkable rapidity. The shortest convalescence was that of a young man of twenty-four, who walked safely after three months. Eight months, however, was the average length of convalescence.

In collecting data for these conclusions my difficulties have been very great. Fortunately many of the ultimate results appeared in the hospital records, and a great number of the patients answered my notes of inquiry. The results, as regards deformity, were especially gratifying to note. The worst deformities were from crushes and horse-kicks; but after the lapse of years they have frequently become less noticeable, and very rarely have the functions of limbs been impaired after permanent bony union.

It seems fair to briefly conclude from this hasty review of so extensive a subject that, though the mortality is relatively high, still we have made within recent years a decided advance in our treatment of this class of cases; and that our success is not so much due to any special variety of apparatus or method of treatment, as to our perfection of technique in working on the broad lines of aseptic surgery.

Clinical Department.

SATURATED SOLUTION OF POTASSIUM PERMANGANATE IN THE TREATMENT OF CHRONIC ULCER.

BY F. B. WAUGHOP, M.D.,
Intern at Boston City Hospital.

LAST summer, in the surgical out-patient department of the Boston City Hospital there were a number of very obstinate cases of chronic ulcer. Poultices of corrosive sublimate (1-1000), creoline (1-1000) and of Labarraque's solution were faithfully employed; as also strapping and the tin-plate method; but without success. Iodoform, aristol and calomel powders were also unavailing.

Permission was then obtained to try the saturated solution of potassium permanganate on these cases. The results were extremely gratifying. One typical case is herewith submitted in full and a summary given of twenty-four others—ulcers, abscesses, old sinuses, etc.

CASE VIII. Ulcer just above left internal malleolus. Size of a quarter-dollar and one-quarter of an inch deep, the bottom being covered with a greenish slough.

This ulcer had been present for four years, with very little variation. It had been treated at various times with poultices of corrosive sublimate (1-1000), the last time once every two days for three weeks. The poultices served merely to stop the sloughing without showing a tendency to heal.

Permanganate Treatment.—The slough was swabbed out, and the ulcer flooded for ten minutes with the permanganate solution (severe smarting being produced the first two minutes). It was next sponged dry and loosely packed with narrow strips of gauze soaked in the fluid. A heavy permanganate poultice (gauze three inches square, dripping-wet with the solu-

tion) was then applied, covered in with oiled paper, and bandaged as lightly as possible with cheese-cloth. This method was repeated every day for a week. On the eighth day the granulations were flush with the surface. Two days of subsequent treatment with eucalyptus vaseline was followed by the formation of a pellicle over the granulations. (Patient disappeared.)

CASE I. Gangrenous ulcer of leg. Size of dollar, and three-quarters of an inch deep. Corrosive three weeks, without effect. Permanganate heals in ten days.

CASE III. Old ulcer of leg. Superficial, two inches by one and one-half inches. Corrosive creoline, flaxseed, and boric acid ointment five weeks, without effect. Permanganate applied every other day, heals in ten days, that is, five applications were made.

CASE X. Ulcer of leg, two years' duration. Three inches in diameter by one-quarter of an inch deep. Bread-and-milk poultice two months, without effect. Permanganate, in three weeks, reduces ulcer to one-half the size. (Patient disappears.)

CASE XI. Ulcer of leg, twelve years' duration. Size of quarter-dollar, one-half inch deep. Corrosive four months, without effect. Permanganate heals in six weeks. (Patient came only twice a week, and was on his feet constantly, doing heavy work.)

CASE XII. Ulcer of leg. Three inches by one and one-quarter of an inch deep. Corrosive one week, without effect. Permanganate every other day for three weeks reduces to a superficial ulcer the size of a dime. (Patient disappears.)

CASE XIII. Ulcer of leg. Size of dollar, and three-quarters of an inch deep. Very foul. Tar ointment six weeks, without effect. Permanganate heals in fourteen days.

CASE XV. Ulcer of leg. Two inches in diameter and one-eighth of an inch deep. Corrosive two months, without effect. Permanganate heals in seventeen days.

CASE XX. Ulcer of leg. One inch in diameter by half an inch deep. Linseed poultices, carbolyzed ointment five days. Action too sluggish. Hastened to a cure by permanganate in eleven days.

CASE XXIV. Ulcer of leg. Size of a half-dollar; one-quarter of an inch deep. Permanganate produces severe dermatitis. Heals slowly under iodoform ointment in nine weeks.

CASE XXVI. Ulcer of leg. Size of dollar, three-eighths of an inch deep. Corrosive two weeks, without effect. Permanganate, used every other day, heals in fifteen days.

CASE XXVII. Ulcer of leg. Tuberculous? Two and one-half by one and one-half by one and one-quarter inches. Corrosive seventeen days, without effect. Permanganate, at irregular intervals, heals in a month.

CASE XXXI. Ulcer of leg. Three by two by one and one-half inches. Corrosive two months, without effect. Permanganate heals in two months. (Patient came only twice a week and was constantly doing heavy work.)

CASE XXXIII. Ulcer of leg. Two and one-half inches in diameter and three-fourths of an inch deep. Permanganate in fifteen days reduces to about one-half the original size. Then twenty days of flaxseed poultice. Ulcer remains stationary, and sloughs a few times. Then healed by permanganate in seventeen days.

CASE IV. Abscess of arm. Size of quarter-dollar, and one-quarter of an inch deep. Packed one week with iodoform gauze. Remains sluggish. Packed

with permanganate gauze, (that is, strips of gauze wet with permanganate). Well in five days.

CASE XIV. Abscess of forearm. One-quarter of an inch in diameter by three-quarters of an inch deep. Packed with corrosive three days, without effect. Permanganate gauze cures in one week (five applications).

CASE XVI. Abscess of abdominal wall. One and one-half inches in diameter, superficial. Iodoform ointment six weeks, without effect. Permanganate gauze heals in fourteen days.

CASE XIX. Abscess of arm. Size of dime, superficial, very foul. Aristol ointment two weeks, without effect. Permanganate gauze heals in one week.

CASE XVII. Old suppurating sinuses along course of palmar tendons. Hydrogen peroxide and iodoform gauze ten weeks, without effect. Permanganate gauze (used every other day) heals in five weeks.

CASE XVIII. Suppurating gland of neck. Packed with iodoform gauze two weeks, without effect. Permanganate gauze heals in two weeks.

CASE XXIX. Cellulitis of thigh. Corrosive and iodoform gauze sixteen days, without effect. Permanganate heals in twenty-six days.

CASE V. Crushed fingers, sloughing. Iodoform gauze and creoline for one week. Too sluggish; little progress. Permanganate heals in ten days.

CASE XXII. Sloughing lacerated wound of hand—gunpowder. Iodoform gauze six weeks. Improvement steady, but too slow. Laceration reduced in ten days by permanganate, from size of dollar to complete disappearance.

CASE XXV. Crushed foot, sloughing. Eucalyptus vaseline three weeks, and black wash two weeks, without effect. Permanganate heals in sixteen days.

CASE XXI. Sloughing chancroids. Aristol ointment for twelve days, without effect. Permanganate heals in six days.

The above are fair examples. Several hundreds of these non-syphilitic cases were treated in this manner during July, August and September, 1893.

The main disadvantage is the pain, which may be very sharp from one to five minutes after application (sometimes twenty minutes, in the case of anal fistula). It then ceases altogether. Rarely, also, a dermatitis is produced.

If the granulations became over-stimulated, weak myrrh wash, lead and opium wash, or some one of the antiseptic powders, or bland ointments was substituted for permanganate until the indications ceased. Moreover, permanganate was usually supplanted by one of these dressings so soon as the ulcer was filled even with the surface, in the normal process of healing.

The patients mentioned above as "disappearing" were those who considered themselves cured, and felt too busy to make their final appearance at the hospital. The corrosive used in the above tests was always 1 to 1,000.

Very good results were obtained in a few cases of anal fistula which were slow to granulate after operation.

Saturated solution of oxalic acid was found to be the best reagent for removing the stain from the hands.

AN International Congress of Sea Bathing and Marine Hydro-therapeutics will be held at Boulogne-sur-Mer from July 25th to 29th.

Medical Progress.

RECENT PROGRESS IN ANATOMY.

BY THOMAS DWIGHT, M.D.

METHODS OF TEACHING ANATOMY.

THERE has been a good deal of writing on this ever fresh, though well-worn controversy, in the English medical papers towards the close of 1893. The central figure in the discussion is Professor Macalister, perhaps the leading anatomist of Great Britain. He wrote a paper¹ in which among other things he discussed the relation of the study of frozen sections to dissection. Without depreciating the latter he taught that the former should be used for supplementary study. Dissection he defines as the art of removing the connective-tissue from around parts so that they can be properly seen. This must, of course, disturb the relative position of parts. "The most skillful anatomist, when he opens the body cavities, must displace the viscera in relation to the landmarks, and cannot avoid doing this to such an extent that, like the fallen Humpty Dumpty, all the members of the Anatomical Society of Great Britain and Ireland cannot put them back as they were before. . . . Dissection is the only way of learning structure and details; sectional study is the only way of learning relations."

This teaching did not please the old-fashioned anatomists who must of late have been chagrined at seeing the rise of new methods. Mr. Thomas Cooke² says, "The conception put forth by Professor Macalister is not new. It is substantially the same—popular errors are long-lived—with which I was familiar as a student in Paris that to the surgeon, the body (to use the metaphor of the day) should be, so to speak, like glass-transparent." He then goes on to prove, what every one will admit, that this is not necessary for tying arteries which are reached by following certain successive guides. In regard to the statement that the study of frozen sections is the only way of learning relations, he says that it is only some twenty years since these were heard of, and asks "Were anatomical relations but imperfectly understood by Callender, Fergusson, Wood—to name only British surgeons who are no longer with us?" No one seems to have replied to this challenge, but trusting to three thousand intervening miles of ocean, we venture to say that we do not believe one of those surgeons knew the position of the stomach, the shape of the liver, of the spleen or of the pancreas; we may add that Wood taught the true relation of the arch of the aorta which he had learned by the sectional method somewhat crudely applied.³ Symington in an address extols frozen sections, Cunningham uses them freely. We are sure that they have come to stay in Great Britain and Ireland, despite the old-fashioned exponents of what Goodsir called "scalpel and forceps" anatomy. We trust that this will never be superseded but only supplemented by modern methods.

Another point about which the discussion has raged is the value of embryology and morphology in the anatomical course. Macalister holds that anatomy taught from a morphological standpoint is more inter-

¹ British Medical Journal, October 21, 1893. There seems to have been a previous pamphlet by Mr. Thomas Cooke, which we have not had the advantage of seeing.

² The Lancet, November 4, 1893.

³ Journal of Anatomy and Physiology, vol. III, 1868.

esting, more intelligible, not less practical. Mr. Cooke⁴ retorts in effect, not without justice, "Yes, because you know these things; but they would not be worth much if taught by one who had crammed them."

This is one of the questions which, it seems to us, can never be categorically answered, because the proper solution depends on the knowledge and the good sense of the teacher. He will make his lectures both more valuable and more interesting by giving glimpses of something beyond, thus explaining facts like the difference of the right and left recurrent laryngeal nerves, which at first sight seem unaccountable freaks; but his tact must not let him wander too far.

THE INFLUENCE OF FUNCTION ON THE SHAPE OF BONES.⁵

Dr. R. Havelock Charles, Professor of Anatomy at Lahore, has written two papers of peculiar interest on the bones of the lower extremity of the natives of the Panjab. At the beginning of the second paper the author gives a summary of the first, which we will quote in his own words, almost in full: "It was shown that the articular surface of the head of the femur was relatively and absolutely greater than in the European, and that it was prolonged so as to adapt itself to the modified *facies lunata* of the cotyloid cavity. That the upper surface of the internal condyle of the femur is partly articular. That the upper surface of the internal tuberosity of the tibia slopes considerably down and in, being never flat. That the external tuberosity has its condyloid articular surface convex from before backwards, and that the articular area is well prolonged down posteriorly. That a facet or facets were to be found on the anterior surface of the lower extremity of the tibia for articulation with similar surfaces on the neck of the astragalus during extreme flexion, or during extension or extreme adduction of the ankle-joint in the squatting and sartorial postures. That on the neck of the astragalus were one or two facets—one external, one internal—the latter continuous with the pyriform malleolar articular surface."

The application of these facts is in brief that the orientals do not sit in chairs, but habitually either squat or sit crossed-legged, for which positions these modifications offer distinct advantages. Now characteristics similar to these are found in the oldest prehistoric bones, and have been advanced as evidence that the knee could not be fully straightened, nor the upright position maintained. They show nothing of the kind, for the native of the Panjab can stand as straight as any, though he can squat as civilized races cannot.

Professor Charles argues that while orientals have retained the sitting postures of their ancestors, Europeans have not, and consequently have lost through disuse the bone peculiarities pertaining thereto. The oriental, on the contrary, inherits as young bones proclaim, "variations in structure acquired by his ancestors, and transmitted, with accumulations due to continuity of like habits, as useful heritages." Hence he concludes the transmission of acquired characteristics is possible.

This very important line of argument that certain peculiarities of ancient bones depend upon function and posture, has been already pursued by Mr. Arthur Thomson and by Manouvrier.

A DIGITO-DORSAL MOVEMENT PECULIAR TO MAN.

While reading this paper by Monsieur Eugène Mouton⁶ we have repeatedly asked ourselves whether it was meant as a joke, or as a satire, or as a serious communication. We have finally accepted the last alternative, though not without some misgivings. The movement in question is made as follows: put the forearm behind the back with the palm outward; then flex the wrist as much as possible and turn the palm in. Then extend the wrist and stretch the fingers out as high up the back as possible, that is to the fourth dorsal vertebra. Thus man can touch with his fingers all parts of his body, which according to our author no other animal can do. This is indeed self-evident till we come to the monkeys and apes. The author found that he was able forcibly to put the arms of the monkeys callithrix and rhesus into the required position, but that they did not execute it naturally. This could not be done to the orang nor the gibbon. The very length of the arm made the movement impossible. For the same reason it would seem to be impossible for the chimpanzee and gorilla, though the test could not be made. To our mind the most interesting point in the paper is the additional evidence that some of the lower monkeys more closely approach man's bodily structure than do the so called anthropoids.

THE RELATIONS OF THE HEART AND LUNGS TO THE ANTERIOR CHEST WALL, AS DETERMINED BY COMPOSITE PHOTOGRAPHY.⁷

Dr. I. S. Haynes has written a very interesting paper on this subject, which we do not mean to undervalue when we say that the method is the best part of it; for we cannot accept conclusions based on the analysis of only three series of observations. The method is in brief as follows: By way of stating positions not easily referred to cartilages he draws an imaginary median line downward from the supra-sternal notch and at definite points on it draws lines at right angles to it of known length. Thus in one subject he describes the position of the apex as two and one-quarter inches to the left of the median line at its seven-inch point. The heart is usually injected from a carotid with a thin plaster mixture which should distend it moderately. The nipples are located according to the method just given, then cut through the middle and their positions marked. All soft parts down to the intercostals are taken away and the surface of bones and cartilages cleaned. "Now place a narrow tape-measure . . . from the supra-sternal notch, along the middle line to below the ensiform appendix. Upon each cartilage and rib indicate the distance in inches, measured transversely from the mid-sternal line, by narrow slips of paper as long as the cartilage or rib is wide and placed vertically upon the same to the number of four or five on either side of the middle line." These are to help in determining the position of the various ribs and cartilages. The camera is set vertically over the subject. A tube for inflation is put into the trachea. Two photographs are then taken, on Plates A 1 and 2, in expiration. The lungs are next inflated, and two views (B 1 and 2) are taken in inspiration. The air having been allowed to escape, the sternum is removed from the level of the lower edge of the first cartilage to that of the upper edge of the seventh. The cartilages and ribs are taken with it for

⁶ L'Anthropologie, 1893, tome iv, No. 4.

⁷ New York Medical Journal, 1893, vol. ii. (Vol. 58.)

a distance of four or five inches from the median line. The pleuræ are not opened. The lungs are again inflated to the same degree as before, and Plate B 1 is again exposed. The pleuræ are then removed, and Plate B 2 is again exposed. After the escape of the air, A 1 is exposed showing the state in expiration with pleuræ gone and pericardium remaining. The front of the latter is then removed, and A 2 exposed. We are not told whether the author then proceeds to combine the corresponding plates of different subjects, but from the illustrations we infer that this is not done.

As we have implied we think that a far larger series is needed before the results can be quoted. We will merely say now that Dr. Haynes finds the apex much nearer the median line than it is generally given. We would venture to suggest that in future observations it would be well to entirely ignore the nipples as landmarks, owing to the uncertainty of their position even in males.

REPRODUCTION OF THE UPPER AIR-PASSAGES BY PLATING CASTS, OBTAINED BY THE CORROSIVE METHOD.*

Dr. B. Alexander Randall strongly advocates this proceeding. The recommendation is by no means new to us, but it has great merits which make it desirable to discuss it. As Dr. Randall points out, a cast locks up a good deal of expensive fusible metal. Further, being of the nature of a negative in which cavities are represented by solids, it requires a certain amount of mental turning inside out, which is often confusing. This would be obviated by an electrotype plating, which has the further advantage of being fit to cut into slices, thus giving new and instructive views. A final point, which Dr. Randall does not mention, is that even in a few years fusible metal casts of such weight as those of the upper air-passages tend to become distorted. This is a very serious drawback. In our opinion metal casts should always be electrotyped when their nature admits of it.

THE RELATION OF THE HEPATIC ARTERY TO THE PORTAL VEIN.⁸

Dr. Retterer, finding discrepancies in the accounts of this point of anatomy, has studied it for himself. He finds that the hepatic artery must be divided into two parts. At the beginning of its course before it is in relation with the portal vein, it is in a posterior (more dorsal) plane. After reaching the vein it turns round it, lying anterior to it in the remainder of their course to the liver.

THE PTERYGO-SPINOUS LIGAMENT (OF CIVININI).¹⁰

This ligament, which is occasionally represented by bone, is of surgical importance in the operation of resecting the third division of the fifth pair of nerves, and we believe has already been referred to in these "Reports." In its simplest state it is a fibrous band passing from the external pterygoid plate to the spine of the sphenoid, and consequently a little external to the foramen ovale. The committee of collective investigation in Great Britain and Ireland have received 218 answers as to the ligament, and 104 as to its relation to nerves. The ligament is wanting, or merely represented by membrane, in about 20 per cent. of the

cases. It is a fibrous band in about 65 per cent. It is partly ossified in about 10 per cent., and completely so in about 3 per cent. The relation of the nerves does not appear to have been reported with many details by most of the observers. The inferior maxillary nerve, which the editors assume to include merely the inferior dental and lingual nerves, passed outside of the band in 92 instances, and below it in 12. The ascending branches naturally are in no immediate relation to it.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

JOHN T. BOWEN, M.D. SECRETARY.

REGULAR Meeting, Monday, February 26, 1894, the President, Dr. C. F. FOLSOM, in the chair.

Dr. J. H. WRIGHT, by invitation, showed

CULTURES OF THE GONOCOCCUS FROM VARIOUS ORGANS.

Dr. W. T. COUNCILMAN showed a

SPECIMEN OF INTESTINAL OBSTRUCTION.

This specimen is interesting from the extraordinary manner in which the strangulation was produced. The symptoms came on suddenly, and the patient died sixteen hours afterward. The entire small intestine lies on this plate. At the lower portion of the plate there is a large mass of intestine, which is intensely congested and hæmorrhagic. The lumen was filled with almost pure blood. Thus the strangulated portion comprises about one-half of the small intestine. A portion of the mesentery attached to the strangulated intestine is also intensely congested, thickened and hæmorrhagic. A distinct band of constriction separates this portion of intestine from the other. Around this, what appeared to be a loop of intestine was wrapped. At first it was difficult to understand the condition. It seemed as though the strangulation was due to the mass of intestine having passed through a loop in the mesentery immediately beneath the intestine. On emptying the gut and examining the constricting band more closely, it was found to be the diverticulum of Mæckel which had become wrapped around the mesentery, with the end passed under, making a complete tie. I here reproduce the condition. Although intestinal strangulation due to Mæckel's diverticulum is not at all uncommon, it does not usually take place in this way. The end of the diverticulum may become attached to the peritoneum in various places, and through the loop so formed the intestine may pass. It is difficult to see just how the condition I show here could have arisen. The end of the diverticulum which had passed under the loop was greatly swollen, and this acted as a regular button, and could not return.

Dr. E. N. WHITTIER read a paper on

DIGESTIVE PARESIS.¹

Dr. E. G. CUTLER: I have nothing to add to what the reader has said. I can simply reiterate what he has so very well expressed, that I have been frequently disappointed in following out the carefully laid down

* The Journal of the American Medical Association, vol xxi, 1893.

⁸ Journal de l'Anatomie et de la Physiologie, 1893.

¹⁰ Journal of Anatomy and Physiology, October, 1893, vol. xxviii.

¹ See page 460 of the Journal.

rules and methods of treatment which have been proposed for the cure of diseases of the stomach and of the intestinal tract. I have tried to use drugs according to the methods of those people who have written on the subject of intestinal antiseptics, and have been quite disappointed at times in the results which I have obtained. I have been led at times to suppose it was some error of mine in the exhibition of these remedies. It is a pretty difficult subject, and I should say of the different cases which I have had under treatment, each one was a case in a category of its own; there were no cases which could be grouped except in a very coarse way. It is an interesting subject, and apparently the success which most of us obtain in the treatment of these diseases is not very great. I see quite a number of patients who have been through the hands of others, and I see others treating quite a number of cases that have been through my hands, so that I think we are all considerably disappointed in the use of many of these remedies which the doctor has spoken of. It seems as if something might be got from the laboratory study of excreta. Comparatively little is known of the feces. I have had occasion recently to see that in having some examinations made at the different laboratories. The chemists do not seem to be able to furnish us very much that is of practical use here. The same thing is true to a less extent of the bacteriologists. There appears to be a good deal of work yet to be done.

DR. H. F. VICKERY: The paper brought a remark of Ewald's to my mind; at least, he is quoted as having said that after the most careful study of the mechanical and chemical conditions of digestion, there is beyond it all a certain organic influence which escapes him and makes the problem almost too difficult to set down in definite language with a definite answer. The late Dr. Flint somewhere has said that he never knew anybody who followed an exact dietary who was not a dyspeptic. The influence of the mental state upon a person in these conditions is certainly very great; the same person, everything else the same except good fortune or bad fortune, one time will be comfortable in his digestion, another time not. Some of the greatest sufferers from the functional kind of dyspepsia look so very well that they again suggest that there is an organic or nervous element very strong in the causation of the disease, and which we have got to play upon in the cure of it. I share the doubts that have been forced upon others by their efforts to use antiseptics. If I understand the physiologists, the bacteria are necessary for the digestion of meat, so that if we made the intestine perfectly free from bacteria we might be worse off than we are now. I think that washing out the stomach in certain cases acts as an aseptic process, lessening fermentation not merely by emptying out a load of material, but by getting rid of a lot of germs which poison whatever food is taken.

DR. J. G. MUMFORD read a paper entitled,

COMPOUND FRACTURES.²

DR. A. T. CABOT: I think we are all very much indebted to Dr. Mumford for his very careful presentation of the subject, and the enormous amount of work he has done in bringing it into shape to give such exact results. In comparing the cases he has worked over with cases at large, I think we must remember that most of these hospital patients are dirty people

who have been injured at a time when the limb was not prepared for a compound injury, and consequently, a good many of these injuries reach the hospital with bacteria already planted in the culture media supplied. I should think, as I was able to gather from his statistics, that the number of cases of suppuration about corresponded with what one would expect from sepsis occurring before the patients reached the hospital.

There is no question that a considerable amount of dirt may be introduced into a wound, and, under favorable conditions, the micro-organisms so introduced may be afterwards made inert and destroyed by the action of the tissues. I think that this power of the tissues to destroy the bacteria introduced is one reason why wounds that are closed up tightly do so much better than those that are treated by putting in extensive drainage, as in the previous plan of treatment. In old times, a leg coming in with fractured tibia, and with tissues extensively lacerated, was laid freely open and riddled with drainage-tubes in every direction. The result was that large openings were made, through which micro-organisms could enter, and the irritation of the tubes led to the formation of fluids, in which any organisms so entering, or which had been introduced at the time of the injury, could grow and propagate.

I think that in the treatment of these cases there is no question that the careful irrigation, washing out of the grosser material, dirt, etc., that has been introduced is extremely important. It is not probable, however, that washing out ever entirely removes all the micro-organisms that have been introduced, and it is probable that their final destruction is wrought by the tissues themselves in the way I have indicated. It seems to me that these cases, particularly those compound fractures in which joints are implicated, really show the most triumphant results from aseptic and antiseptic surgery that we now see. A little impurity introduced into the comparatively non-vascular cavity of a joint has much less chance of being properly removed by the action of the tissues than has an equal amount of septic material when introduced into the peritoneal cavity. In old times, we used to regard an abdominal operation as the acme of aseptic or antiseptic achievement. I think, however, that these joint cases are much more striking, and are better tests of the thoroughness of the asepsis. In view of that fact, it seems to me that a joint that has suffered a compound fracture, and in which mobility has been preserved by aseptic treatment, is really one of the greatest triumphs of aseptic surgery. I confess that I was surprised at Dr. Mumford's statement of the number of such movable joints obtained. I had not supposed we were doing as good work as that. When we consider the mechanics of the elbow-joint, and think that a moderate amount of inflammation would fasten those intricate joint surfaces together so that they would not afterwards move on each other, I think these results are remarkable.

Lastly, in regard to the methods of putting up these fractures. Of course, the main principles which are to be observed are these: thorough cleanliness, asepsis as far as can be obtained, and immobility. It does not very much matter in what way the immobility is obtained, provided it is complete, or approximately so. In the case where we operate and make antiseptically a compound fracture, as by section of a bone, we are perfectly sure from the start that we have not intro-

² See page 465 of the Journal.

duced organisms, at least, have taken every precaution against it, and we can use fixation with plaster, expecting not to remove that dressing until union of the bone has been pretty thoroughly established. In these cases, however, where the patients are brought in with a dirty leg or dirty arm with a compound fracture in it, and where there is a very strong chance of suppuration, it seems to me that we expose our patient to some risk by closing in that wound, after making it aseptic as possible, by enclosing it in a stiff dressing. In cutting off a plaster bandage, there is a certain amount of motion, churning up of the fracture; and in putting on the next plaster that is to take the place of the one taken off, there is a certain amount more of churning up, and to avoid that, I think fixation splints have their advantage over the plaster. They enable you to watch the limb more carefully during that period during which there is fear that suppuration may establish itself.

DR. R. W. LOVETT: The only part of compound fractures that I am competent to discuss is the later history, which I see as an out-patient surgeon; and Dr. Mumford's paper makes plain what I had not realized so fully before, how long had been the immobilization of these patients before they were competent to come as out-patients and see about having the plaster removed. There are some points I have been interested in observing, and one is especially with regard to fractures of the leg in cases where the joint has not been involved. After weeks and months of immobilization the joint is almost always stiff, and it has been perfectly well demonstrated by experimental work, especially by Dr. Phelps, of New York, that prolonged immobilization of the healthy joint did not result in ankylosis except in the case of very old persons or persons markedly rheumatic; that seems to be perfectly well borne out by the cases one sees coming to the out-patient department, and motion slowly comes back in these joints that have been fixed so long by the use of hot water and massage. If the foot has not been put in a proper position at the time of the injury, and is not fixed in the position of a perfect right angle, the strain on the tendo-Achillis is felt at once on beginning to walk, and I am sure that the period of disability is very much prolonged by the slightest dropping of the toe. Another point that comes up, is with regard to the swelling and the disturbance of the circulation in these legs that have been so long immobilized. Some years ago I went to Dr. Warren and got the literature there was with regard to it, and found it was a subject on which there had been very little formulated and about which very little was known. Dr. Edward Reynolds and I got some dogs and went to the Medical School for the purpose of doing some experimental work on the subject. The legs of the dogs were broken, but we found it impossible to reproduce the swelling. We immobilized them for long periods, but we could not get reproduction of the swelling. The disturbance of circulation, the coldness and blueness that follow removal of the plaster in some of these compound fractures of the leg and the tremendous swelling and infiltration that follows in some cases is a pretty serious problem. In some of the cases it has not seemed to yield to anything; in other cases it was benefited by massage or hot water and in the majority of cases it wears off slowly. I think the causation of the swelling is a matter about which practically nothing is known. In some cases which have been fixed

for months there is comparatively little of it, but it forms a most troublesome and obstinate complication that is to be dealt with in the later stages of these long continued fractures.

Then another point is with regard to the breaking down of the arch that follows the long immobilization of the leg. I fancy it is due to the same set of phenomena that cause the swelling and disturbance of the circulation, but after months of fixation in the plaster bandage and after the stiffness of the ankle has been disposed of, there begins to be felt in a large number of cases, a pain which indicates that the arch of the foot has given way, and one can notice in looking at the foot that it is somewhat pronated and that the weight does not come down through the foot but inside of it. In these cases relief is almost always given by the application of a felt pad to support the arch of the foot, a couple of layers of felt are cut so as to fit into the hollow of the foot and support the arch and are applied outside of the stockings. This seems to be so much the case that in my last service at the out-patient department all cases of fracture, simple and compound, when the splint was removed, were dressed at first with a bandage and felt pad under the foot to support the arch. The results were satisfactory as far as they went. It seemed as if the people regained the power of walking with less discomfort and disability than when they were left to walk directly on the foot. The impressions of these feet carried out this idea that the arch was broken down. A permanent flat-foot had resulted in a certain number of cases of fractures done in previous years where they came to apply for relief from flat-foot.

DR. J. E. GOLDTHWAIT: I fear that what I have to say will be rather out of place in this discussion, as Dr. Mumford has carefully avoided the subject of the direct fixation of the fragments; nevertheless, as the specimens have been prepared and as they have to do with the treatment of compound fractures, it seems to me that I am justified in presenting them. I wish to say, at first, that the suggestions which I have to make, are simply the result of some experimental work, and that as yet they are simply experimental and theoretical, not having been used upon any patient. I would also say, that I do not advocate this line of treatment for every case of compound fracture, but only for those very severe fractures with laceration of the soft parts, in which the immobilization of the fragments in the correct position is so difficult. The class of cases for which the various forms of wire suture have been devised, and also for which Langenbeck, Volkmann and others have devised and used the different osseous splints.

A year ago Dr. Senn, in his address before the American Surgical Association, described a method in which he used ferrules of bone for this purpose, they being slipped on over the ends of the broken bone. The difficulties with this method were the making and fitting the ferrule, and that later on it was necessary to remove this ferrule by a second operation.

With the hope of finding some absorbable substance, that at the same time could be easily and quickly applied, I have been experimenting for some time, and of the various materials used decalcified bone has proved to be the best; and in pieces two or three inches long and one-eighth of an inch square is quite firm enough for the purpose. Several of these pieces can be used, being applied as coaptation splints and these

held in place by silkworm-gut ligatures. Another way which accomplishes the same result, is to use a segment of the shaft of a bone about two inches long split longitudinally. This makes a trough into which, after it is decalcified, the fragments of the bone rest, while along the upper surface one of the small decalcified splints, before described, is applied, and the whole held in place by the silkworm-gut ligatures.

All of the material used is absorbable, so that a secondary operation for its removal would not be necessary; the splints do not require much fitting; and they can be prepared and kept for use the same as ligatures, and other surgical supplies.

DR. CABOT: In regard to the method of fixation of the ends, which was not discussed in the paper but which I think is important, the difficulty has always seemed to me with those complicated methods proposed by Senn and others that they necessitate too extensive an injury of the soft parts. I have always tried to keep the soft parts not separated from the bone, and it seems to me any method which requires for its proper performance a separation of the soft parts from those ends which are going to unite, is in that degree faulty. I am interested in what Dr. Goldthwait has said about using silkworm-gut for tying around these splints. Lately, since I have used the silkworm-gut more and more, I have firmly convinced myself that it is quite strong enough for the ordinary suturing of bone, and I question whether a few silkworm-gut sutures between the fractured ends of the bones, would not accomplish as much fixation as is ordinarily necessary and with a less introduction of foreign material than in any of the more complicated methods.

DR. GOLDTHWAIT: From what little experience I have had, I should quite agree with Dr. Cabot in his hesitating to strip the bones of the soft parts, and also that in the cases in which wire can be used, I should think the silkworm-gut would be sufficient, but there are a certain number of cases in which, as the result of a severe crush or twist, the soft parts are lacerated and torn from the fragments, making it very difficult to maintain the correct apposition. Also the bone at times is so finely comminuted and the edges so ragged that it is difficult to pass a silver-wire or any suture directly through the bone so as to hold them in place. It was for this small class of cases that I suggested this mode of treatment. In exposing the bone to apply the suture, if it is necessary to free any of the soft parts, by all means do not disturb the periosteum. If you notice in the illustrations passed around, the splints raise the sutures so that the intervening space between the splints is free, and no pressure is brought upon the periosteum in these places so that the circulation is not disturbed.

Recent Literature.

A Laboratory Guide in Urinalysis and Toxicology. By R. A. WITTHAUS, A.M., M.D., Professor of Chemistry and Physics in the Medical Department, University of the City of New York, etc. Third edition. New York: William Wood & Co. 1893.

This book, which has been prepared solely for laboratory use, contains the work which is followed by the junior students in the Medical Department of the University of New York. It is, we presume, primarily

intended as an aid to the author's own classes, and is well adapted for that purpose. We can recommend it as a useful laboratory guide. In this edition a system of qualitative analysis not contained in the earlier editions has been added.

Hernia: Its Palliative and Radical Treatment in Adults, Children and Infants. By THOMAS H. MANLEY, A.M., M.D., Visiting Surgeon to Fordham Hospital; Member of New York Academy of Medicine, American Medical Association, New York State and County Associations, International Medical Congress, Pathological Society, National Association of Railway Surgeons, etc. Philadelphia: The Medical Press Co., Limited.

This book presents the subject of hernia, and tries to accord "to each therapeutic resource its due merit, and to strive to indicate the precise limitations of each." In these days we can hardly glance at a journal, but what a new operation for the radical cure of hernia is brought forward. In this state of unrest, it would be difficult to have any book thoroughly up to date. Dr. Manley has succeeded, however, in incorporating in his book most of the recognized operations. The reader is never left in doubt as to the value of a proposed operation, for the author states clearly his belief in the different measures presented. There is at times obscurity in the author's writing; as for instance, on page 13, the following paragraph occurs:

"The change in the pelvic lines, curves and angles, and the transmutation of tissue; the widening lumina of the emunctory canals, in obedience to the incessant, though intermittent movements of their contents, each and all contribute their share towards effecting a symmetry of perfection and the firm closure of the inguinal femoral and umbilical portals."

The binding is fair, the cuts are indifferent, and the printing is bad.

Marinesanitätsordnung. Band I, *am Lande*; Band II, *Beilagen*; Band III, *am Bord*. Berlin: E. S. Mittler & Sohn. 1893.

These three volumes contain the official sanitary regulations, blank forms and other material relating to the Naval and Marine Service of the German Government.

Volume I contains the regulations to be observed in hospitals, stations and all places on shore.

Volume II contains the blank forms which accompany the regulations published in Volume I. They are eighty-five in number, and contain very minute details relating to the management of the hospitals, supplies, food, medicine, baths, heating, lighting, vaccination, and everything relating to the care of the sick.

Volume III contains, first, the regulations pertaining to the care of the sick at sea; and, second, the health regulations of ships, including the ventilation, food-supply, water-supply, clothing, prevention of infectious diseases, poisons and methods of disinfection.

The Year-Book of Treatment for 1894. A Critical Review for Practitioners of Medicine and Surgery. Philadelphia: Lea Brothers & Co. 1894.

This book has been compiled, on the whole, with excellent judgment, and, being in its tenth year, is already well known. It presents to the profession in a convenient form a brief summary of the ways proposed during the year for treating a great variety of diseases. Practitioners will find it a useful book.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, MAY 10, 1894.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE BRANDT METHOD OF PELVIC MASSAGE.

It is rather extraordinary that the author of a method of treatment so peculiar in its character, and intended for the cure of diseases of the female pelvic organs should be a layman. This fact undoubtedly delayed its professional recognition, but now, largely through German physicians who have studied it with Brandt, its claims have become known to the profession at large. These claims are not that his method is a universal remedy for the diseases of women, but that very many of the chronic pathological conditions which are the result of inflammations of the genital tract, and some of the functional disturbances, especially of menstruation, are favorably influenced by this method of treatment. He also claims that displacements of the uterus are permanently cured by the appropriate manipulations, prolapsus uteri of all degrees being no exception to the rule.

There seems no doubt that Brandt can substantiate these claims, and from the reports which a few other operators have made of their results it seems possible for others to accomplish as much.

In estimating the value, however, of any method of treatment, especially one which is recommended for so large a proportion of what may be called minor gynecological affections, two or three considerations must be borne in mind.

In the first place, it must be easy of application and demand no more than the ordinary skill of the average physician. In the second place, it must be as regards expenditure of time and expense on the part of the patient and in permanency of results a marked advance over other methods. And third, it must be free from all objectionable features.

A somewhat careful study of what has been written on the subject forces us to the belief that the method of pelvic massage under discussion does not fulfil any of these prerequisites.

As regards the first, it is conceded even by its warmest advocates that it is well-nigh impossible to so de-

scribe the technique in print that a physician can appropriate and make use of it. Personal instruction and long practice seem to be a necessity, and even then so much delicacy of touch and manipulative skill are required that few could become proficient. These facts alone would prevent its widespread application.

As regards the second point, the length of time required, and the permanency of results, two very important factors in comparing it with other methods, we are forced to the conclusion that even in these respects its claims for recognition cannot be substantiated. We think other forms of treatment would accomplish equally good results in a shorter time. Dr. Matilda Wallin, who for three years was Brandt's pupil and assistant, in a late communication on this subject before the Philadelphia County Medical Society, describes the method in considerable detail, and refers to a case of complete prolapsus uteri, which she saw treated. The patient came to Brandt the 29th of June; on the 9th of September she was well. Who will doubt that with appropriate operative treatment the patient would have got well sooner? Much more would this be true of the numerous minor ailments.

The third point mentioned raises a question which must, it seems to us, suggest itself when this method of treatment is advocated, namely, the effect of this more or less prolonged manipulation of the vagina upon nervous and excitable women. In our opinion it cannot fail to be prejudicial, and in so far nullify any good effect that the massage would otherwise have.

The objections, therefore, which we would feel are valid against the widespread adoption of this method of treatment, are that it is complicated, slower in its action, and not surer in its results than other methods, and has possible objectionable features.

At the same time, we confess that in a modified form and as an adjunct to other modes of treatment, massage is valuable in pelvic disease. It is not the principle, but the elaborate system which seeks too wide a field and attempts too much that we object to. Any method which claims as much as this does must lie within the possibilities of at least all specialists. As it is, its practice will certainly be confined to the favored few who can enjoy special training, and who will make a sub-specialty of it.

TREATMENT OF DIPHTHERIA BY FREQUENT SMALL DOSES OF BINIODIDE OF MERCURY.

PIÉDALLU¹ claims extraordinary success in treating diphtheria by small doses of biniodide of mercury. He has employed this remedy since early in 1891 in very many cases, to the exclusion of the usual local treatment, and without a single death. His formula is as follows:

R. Syrup	1000.00
Iodide of potassium	50.00
Biniodide of mercury	0.50 M.

The dose of this syrup for a young child is a teaspoonful every two hours. The dose would be about

¹ Bull. et Mém. de la Soc. de Thérapeutique, Avril 6, 1894.

one-thirtieth of a grain of the biniodide and about three grains of iodide of potassium. This may seem to the uninitiated rather large dosing, but Piédallu affirms that to obtain the really specific local and constitutional effects of these drugs (a share in which certainly belongs to the iodide of potassium), really heroic doses are required. He has given as much as 300 grammes of this syrup in the course of a week to children from four to six years old. At the end of several hours, eliminated by the mucous membranes, that is to say, the signs of iodism appear: coryza, salivation, etc., and the spittle flows from the child's mouth; then the dose is diminished, enough being still given to keep up the effect. The object of the treatment, in the words of the writer, is "to maintain in the mouth and pharynx a permanent antiseptic gargarism." He advises in case the false membranes are loose, to detach them gently with a spoon-handle, then to touch the denuded surface with a swab dipped in bichloride solution, 1 to 1,000; this may be done two or three times a day.

Piédallu remarks that it is not until the end of forty-eight hours that this treatment shows its curative effect. The false membranes no longer spread, but begin to fall off in a pultaceous mass. In certain rebellious cases, the amelioration does not show itself until the fourth or fifth day, but the remedy must be continued fearlessly, and in doses proportioned to the gravity of the malady.

This treatment is very well borne by children, and is very exceptionally attended with colic, vomiting, or stomatitis. It is well to conjoin with it a rigorous milk diet to ensure activity of the renal function, but when the child desires to eat, light food may be allowed.

Piédallu urges the profession to try this method which he says has given him uninterrupted success for three years. He claims that the mercury and iodide of potassium in being eliminated by the mucous membranes of the upper respiratory passages, constantly oppose their antiseptic action to the specific bacilli, and thus make their habitat unpropitious. Certainly, this kind of treatment is more easily carried out than the local treatment by spraying, irrigation and swabbing.

It will be remembered that when pilocarpine was first recommended for internal treatment in diphtheria, some such action as that above described was claimed for it, but the result of treatment by pilocarpine and by jaborandi was only failure and disappointment.

At the meeting of the Therapeutical Society, there was some discussion of the above mentioned mode of treatment. One of the speakers (Barbier) said that experiments made in Germany and Switzerland demonstrated the bactericidal value of biniodide of mercury and iodide of potassium. As these drugs are eliminated by the mucous membranes, the formula of M. Piédallu appeared to be rational. M. Crequy thought the doses rather large for children, but Guelpa affirmed that children support mercury better than adults.

Others expressed their desire to test the treatment indicated by M. Piédallu, but affirmed their disbelief that any really specific treatment of diphtheria had yet been found.

SCALING THE APPROPRIATION FOR THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE.

THE appropriation for the Library of the Surgeon-General's Office at Washington has been cut down in the House of Representatives from \$10,000 to \$7,000. An effort will be made to have the amount restored to the old figure in the Senate. The petty economies practised by Congress in this and similar matters are as exasperating as are the gross extravagances in other directions where it is supposed votes may be made.

Remonstrances against the action of the House are making themselves heard from many parts of the country. The following resolutions adopted by the Academy of Medicine of Cincinnati express a very general feeling in the Medical Profession:

Whereas, the Library of the Surgeon-General's Office in Washington is of the greatest importance to medical education and to the medical profession throughout the entire country, it is for the public good that it should receive the liberal support of the Government;

Resolved, That the Academy of Medicine desire to enter their earnest protest against the reduction of the appropriation for its annual support from \$10,000 to \$7,000;

Resolved, That the Academy of Medicine urge most strongly the restoration of the former annual appropriation of \$10,000, under which it has become one of the largest and best appointed medical libraries in the world, and without which its continued growth would be seriously crippled.

A similar memorial to the United States Senate is being circulated and receiving representative signatures among the profession in Boston and its neighborhood. With \$7,000 it is impossible to procure even all the current literature.

MEDICAL NOTES.

CREMATIONS IN FRANCE.—There were one thousand and five cremations in France during the first three months of the present year, which is one-third more than a year ago.

PROFESSOR RUBNER TO SUCCEED HIRSCH.—Professor Rubner has been chosen to succeed the late Professor August Hirsch in the Chair of the History of Medicine in the University of Berlin.

A BEQUEST TO THE ELIZABETH HOSPITAL.—The sum of \$25,000 has been given to the Elizabeth, New Jersey, Hospital by some one in New York who formerly lived in Elizabeth, on condition that his name shall not be made public.

BILLROTH'S SUCCESSOR.—Dr. Victor Ritter von Hacker, head of the Second Surgical Clinic at Vienna, has been unanimously recommended by the Professorial College to succeed the late Professor Billroth in the Chair of Surgery in the University of Vienna.

PROFESSOR THOMA. — Dr. Richard Thoma, professor of pathology at the University Jurjew, Dorpat, has moved to Magdeburg to take charge of the general hospital in that city. On his departure from Dorpat he was escorted to the station by his colleagues and a large company of students.

ACQUA DI PERUGIA. — The preparation of that charming old poison known as *Acqua di Perugia* was not so difficult or mysterious as has been supposed. It can easily be made, according to a recent writer, by killing a pig, cutting it up, and salting it down with arsenic. After being cooked the gravy from such a dish is even more fatal a poison than the unserrified metal.

A POPULAR SURGICAL CONSULTANT. — Professor von Bergmann, of Berlin, was recently called to Nikolajew to amputate the foot of an eighty-two-year-old millionaire. It became rumored in the town that the great surgeon would also see other patients in consultation during his short stay, and the crowd of carriages about the door of his hotel became so great that the police were obliged to keep a squad of men on duty to keep the approach from being blocked.

A FATAL LUNCHEON. — The *Lancet* reports the following almost incredible luncheon eaten by an English lad of fifteen years: thirty oranges, an entire cocoanut, cider, a mince-pie, mineral-water champagne, tea, cake and lemonade. Immediately after this feast the boy died of cerebral apoplexy; and the *Lancet* remarks, "altogether the narrative is a melancholy and humiliating reminder that pleasure, above all things, can only be enjoyed in moderation and is poisonous in excess."

THE FATALITY OF SUCCESS. — The *Calcutta Medical Reporter* relates a curious instance of the fatal effects of "continuous performances" with poisonous drugs. A fakir at a fair was accustomed to attract spectators by eating shavings, glass, soap and such dainty dishes, and at last added matches to his diet. As trade was dull at first, he did himself no harm; but his popularity increasing, he was obliged to give some thirty performances a day, and in the glow of his success he died of phosphorus-poisoning.

ADMISSION REQUIREMENTS TO ILLINOIS MEDICAL COLLEGES. — The Illinois State Board of Health has revised the regulations concerning admission to medical schools in that State by depriving the various faculties of the control of entrance examinations in elementary studies, and requiring in place of such examination, a certificate of graduation from a college, a high school, or a certificate from a second-grade teacher. Entrance examination must indeed have been lax when so generous a change raises the standard.

ONE DIFFICULTY IN THE WAY OF AN INTERNATIONAL MEDICAL LANGUAGE. — In a recent discussion at the New York Academy of Medicine upon the possibility of adopting Greek as an international language for scientific purposes, Dr Roosa said that if we were to have an international language, it could only

be by a revolution of teaching methods, and he despaired of such a revolution because the hide-bound notions of college professors were simply beyond any ordinary assault. For a man from New York to talk to men from Cambridge or New Haven as to ways of teaching would be very much as if he should go to the tomb of the Prophet with his boots on.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — During the week ending at noon, May 9, 1894, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 36, scarlet fever 38, measles 31, typhoid fever 13. There were no new cases of small-pox, nor any deaths, during the week. There are now 9 cases of small-pox in the hospital. During the week the State Board of Health received reports of the following cases of small-pox: Natick 1, Worcester 2.

AN AGED PAIR OF TWINS. — There are living in Peterboro, N. H., two maiden sisters who claim, with not improbable justice, to be the oldest twins in the country, as they are over eighty-three years old.

HARVARD MEDICAL SCHOOL. — The course of evening lectures to graduates ended with the lecture given on Wednesday, May 2d. A similar course will be announced for the winter of 1894-5.

A MEDICAL MAGAZINE AT YALE. — A new medical journal will be published next month by the students of the Yale Medical School. It is proposed to have contributions from physicians in Connecticut and New York in addition to work of the students.

THE MASSACHUSETTS STATE BOARD OF HEALTH AND THE PREVENTION OF CONSUMPTION. — The Massachusetts State Board of Health has issued an extended circular on the prevention of consumption in which it suggests that much good might be done if local boards of health would issue a simple notice like the following:

"Consumption is the most destructive disease of New England, the number of persons dying annually from this cause in Massachusetts amounting to nearly six thousand.

"The disease is infectious, and can be communicated from one person to another. The chief danger exists in the expectoration of the sick, and if this expectoration is carefully destroyed little danger need be feared.

"Consumptives should be instructed not to spit upon the floors of rooms, public halls, street and railway cars, and other vehicles, nor in the streets, but into pieces of cloth, or receptacles made for the purpose, containing water, or a saturated solution of carbolic acid (one part of carbolic acid crystals to about fifteen parts of water). Such bits of cloth should be destroyed by fire, before the sputa becomes dry, and other receptacles should be cleansed with scalding water, their contents having been destroyed or otherwise carefully disposed of. Handkerchiefs which may have been used from necessity should be boiled half an hour before washing.

"A healthy person should not sleep in the same room with a consumptive.

"Remember that sputa must never be allowed to become dry."

BOSTON CITY HOSPITAL HOUSE-OFFICERS. — Under the present new regulations of the Boston City Hospital, graduates in medicine of less than three years'

standing as well as undergraduates who have completed three full years of study are eligible as candidates for appointment as house-officers.

NORFOLK DISTRICT MEDICAL SOCIETY.—At the annual meeting of the Norfolk District Medical Society held May 8th, the following officers were elected for the coming year: President, D. D. Gilbert, Dorchester. Vice-President, Robert T. Edes, Jamaica Plain. Secretary and Librarian, James C. D. Pigeon, Roxbury. Treasurer, Edw. G. Morse, Roxbury. Commissioner of Trials, Benjamin E. Cotting, Roxbury. Nominating Councillor, O. F. Rogers, Dorchester. Censors, B. S. Blanchard, Brookline; D. G. Eldredge, Dorchester; H. M. Cutts, Brookline; E. B. Lane, Dorchester; C. W. Sparhawk, West Roxbury.

CONNECTICUT RIVER VALLEY MEDICAL ASSOCIATION.—At the Annual Meeting of the Connecticut River Valley Medical Association, held at Bellows Falls, Vt., May 1st, the following officers were elected for the ensuing year: President, Dr. W. L. Havens, Chester, Vt.; Vice-President, Dr. D. Goodenow, Alstead, N. H.; Treasurer, Dr. E. R. Campbell, Bellows Falls, Vt.; Secretary, Dr. J. Sutcliffe Hill, Bellows Falls, Vt. Delegates to American Medical Association, Drs. Holton, Campbell, Ray, Richardson, Pettengill, Havens, Gleason, Dinsmoor, Prouty and Hill. Delegates to State Societies, Dr. Taylor, to Vermont; Dr. Miner, to New Hampshire; Dr. Staples, to Massachusetts; Dr. Page, to Connecticut.

NEW YORK.

REPORT ON THE BACTERIOLOGICAL DIAGNOSIS OF DIPHTHERIA.—At a meeting of the Board of Health held May 1st, Dr. H. M. Biggs submitted a report on the bacteriological examination of 286 cases reported as membranous croup, made within the past ten months. 229 of these were proved to be true diphtheria by the existence of the Klebs-Löffler bacillus; or about 80 per cent. Six per cent. of the remaining cases were of doubtful character, and the other 14 per cent. were clearly not true diphtheria. The result of his investigations led Dr. Biggs to recommend that so-called membranous croup should be included by the Board of Health in the list of contagious diseases.

THE DEATH OF A CHOLERA QUARANTINE NURSE.—On May 1st there died at Bellevue Hospital a woman whose heroic devotion to duty under the most trying circumstances deserves to be held in remembrance. This was Miss Juliet Henshaw, a professional trained nurse, who was the first one to volunteer in response to the call of Health Officer Jenkins for nurses for the cholera patients on Swinburne Island in the summer of 1892. The number of nurses was very small, but she was so indefatigable in her work of caring for the sick that the percentage of mortality was remarkably low. She won the intense admiration of the physicians in charge by her self-sacrifice and skill; and when her health began to suffer from the strain upon her she was urged to give up her position. She insisted, however, upon remaining at the post of duty

until the disease disappeared. After the cholera outbreak Dr. Jenkins kept her in his employ, and she remained in the service until the latter part of April, when she became seriously ill. She was then transferred to Bellevue Hospital. During the attack from which she suffered the symptoms strongly resembled those of typhus fever, but the autopsy showed that the cause of death was acute yellow atrophy of the liver.

THE "CRAIG" STATE COLONY FOR EPILEPTICS.—The Governor has signed the bill introduced into the Legislature by Hamilton Fish, providing for the establishment of a State Colony for Epileptics, which passed the Assembly by a vote of 96 to 4, and the Senate unanimously. The colony is to be known as the Craig Colony, "in honor of the late Oscar Craig, of Rochester, whose efficient and gratuitous public services in behalf of epileptics and other dependent unfortunates the State desires to commemorate." The statute provides for the purchase by the State of the property heretofore owned by the Shakers, situated near Mount Morris, Livingston County. It includes 1,800 acres of land in one of the finest locations of the Genesee Valley, and the soil is well adapted for farming and horticultural purposes. The supply of water is abundant, the property being divided into two parts by the Cashauqua Creek, which flows through the land in a deep gorge, with a fall of one hundred feet, affording a perfect natural barrier for the separation of the sexes. The Shakers have erected upon the property two groups of buildings, valued at \$75,000, suited to all the purposes of the contemplated colony, which, with slight alterations, will accommodate at least three hundred patients. Indigent epileptics will be received and cared for by the State, but the colony is expected, when fully established, to be nearly self-supporting. There are now more than six hundred epileptics in the poor-houses and almshouses throughout the State.

Miscellany.

THE EFFECT OF ETHER AND CHLOROFORM ON THE KIDNEYS.¹

WUNDERLICH, after the examination of the urine in 125 cases, before and after anæsthesia, draws the following conclusions as to the effect of ether and chloroform narcosis on the kidneys:

(1) An already existing albuminuria is often increased by etherization. No such case in which chloroform was given was observed.

(2) Albuminuria can be caused by narcotization with chloroform and ether, more often with chloroform, the relative frequency with which it occurs after the use of chloroform and ether being 11.5 to 6.9.

(3) As a result of the use of chloroform, casts may appear in the urine. This is less frequent after the use of ether. The relation of frequency is 34.8 to 24.6.

(4) When casts are already present, both anæsthetics have the effect of increasing the number.

¹ Beiträge zur Klin. Chirurgie, Bd. XI, Hft. 2, 1894; Annals of Surgery, May, 1894.

INFANTRY FOOTWEAR.

In spite of all the changes in the tactics of modern warfare, the greater use of artillery in mass and at long range, and the more facile means of transportation of troops, one of the most important elements in the success of an army, and perhaps the prime factor in determining its real value, is the marching power of its infantry, whether for long distance or quick strategic movements. In maintaining this superiority, the chief reliance must be placed, not on the strength, courage or rations of the men, but on the condition of their feet; not on the character of their patriotism, but of their boots. Napoleon appreciated this, and hanged a contractor who stuffed the soles of his shoes; and Wellington is said to have enumerated the three most essential articles of a soldier's equipment as, first, a pair of good shoes; second, another pair of good shoes; third, a pair of half-soles.

Lieut. N. P. Phister of the First United States Infantry calls attention to the general neglect of this important matter¹ in our army. During his observations he has marched about two thousand miles, and has "seen about five per cent. of a regiment of three hundred men disabled for hard marching by sore feet, in a march of ninety miles over good roads, going at the rate of about twelve miles a day; and as a contrast, one company of the eight went through without a sore foot in the entire company, simply because the captain had looked carefully to his men's shoes, and had each man prepared with well-broken, well-greased shoes of proper size. It was not required that the men of this company should wear the issued shoes, but no shoe might be worn without the captain's approval."

The five essentials, each of equal importance for infantry footwear, to give increased efficiency in marching power are: (1) Protection from wear; (2) freedom of action for the foot; (3) lightness; (4) flexibility of the shoe; (5) fit. The first requirement is at present about the only one regarded, and that in a manner which is false economy, and is closely related to the other requirements of freedom for the foot and flexibility. Mere thickness of the leather is no criterion of its wearing power if the skin has no pliability or is poorly tanned.

"Cold-tanned oak sole-leather of proper thickness, and well rolled, to make it compact, is pliable and tough, and, while it costs about one-third more, is well worth the difference." As the middle layer of the tanned hide is fibrous, it cannot be dressed, shaved or pressed to a permanently smooth surface, or one which will wear well, and therefore a piece of leather which has been split or skived down to a required thickness has been so treated at the expense of one of its wearing surfaces, and will not retain dressing, rapidly absorbs moisture, hardens and stiffens till it breaks. "Our soldiers have for years worn shoes from leather of this kind, fuzzy and cloth-like in appearance. The soldiers call them boiler-iron shoes, and they deserve the name."

As regards lightness, there is room for much improvement. The cavalry gives careful consideration to the weight of the horse-shoe. The weight given by experts as proper for a full set of shoes for a cavalry horse of medium size is forty-eight ounces. A pair of soldier's shoes, No. 8, of the latest infantry pattern, weighs forty ounces.

Far more care should be given to individual fit of the shoes. A foot is a foot, and a shoe a shoe—is not a reasonable, wise principle for the quartermaster's department to follow, and a shoe well made from the best material and fitted to the foot is a good economy, even if it cost more—\$4, instead of \$1.89, as at present.

"A cobbler's wagon is a necessity not always provided for. No forge, forge-wagon or battery is more so. Some arrangements for mending the shoes of the soldiers during campaign should always be made. A soldier can and frequently does fight in his shirt-sleeves and bare-headed, nor is his military efficiency impaired by a canvas patch on his trousers; but if his shoes give out or his feet get sore he will not be on hand to fight at all."

Correspondence.

PROPOSED LEGISLATION FOR THE BETTER PROTECTION OF THE COMMUNITY AGAINST QUACKERY.

NEWBURYPORT, May 5, 1894.

MR. EDITOR:—The bill¹ which has recently passed the Massachusetts Senate and will soon come before the Lower House is meeting with favor wherever the importance is recognized of any legislative interference with quackery in its manifold forms. It is a bill which will not offend the extremist advocate of the *laissez faire* doctrine of governmental function, because it does not oppose the right of individuals to employ Christian scientists, faith-curers, magnetic healers, clairvoyants, etc. (see Section II), if they wish, nor does it prevent the quack from responding to the demands of those who have faith in his methods; it simply takes from the latter—unless he has been in practice at least three years—his right to usurp a name and a title which he has not earned by long and laborious study and suitable experience. This bill recognizes the fact that the degree of M.D. cannot be assumed at will by individuals, but belongs to the graduates of legally chartered medical colleges and universities, having power to confer degrees given them by the Commonwealth, or to such as pass the examination of the Board appointed under this bill. It forbids individuals from advertising themselves as physicians and surgeons, using the letters M.D., or title of doctor ("meaning thereby doctor of medicine"), until they have been duly registered, the qualification of registration being the possession of a diploma from a legally chartered medical school, or in default of this, the passing of an examination before a Board appointed by the governor.

The proposed bill cannot be regarded as a bill to suppress quackery, however it may have been misrepresented by its enemies, who say that it is at least "an entering wedge." The suppression of quackery by legislation is something that has never been accomplished since the world began. Considering the fate of previous attempts in this State to obtain medical legislation, it is not probable that for some time any more stringent bill will pass the Committee-room.

Such legislation should always be regarded as primarily and especially intended for the protection of the people, not for the principal benefit of medical men. The Supreme Courts of several States have declared that laws regulating the practice of medicine and surgery are constitutional and valid, being for the promotion of the safety and well being of the community. This decision not only has been rendered by the Supreme Courts of Minnesota, Illinois and New York when confronted by test cases, but the Supreme Court of the United States has affirmed the right of State Boards of Health and State Governments to make rules for the regulation of the practice of medicine.

¹ Journal of the Military Service Institution, May, 1894.

¹ Boston Medical and Surgical Journal April 26, 1894, page 36.

It is true that many of our foremost physicians look with indifference if not with positive disfavor upon all such laws; chiefly for the reason that it seems to be impossible to obtain such legislation unless physicians demand it and work to obtain it. There is this hardship, that physicians cannot ask for such legislation for the benefit of the public without seeming to ask for it from a mere selfish motive. It has always, moreover, been the case that in States and countries where stringent laws regulating the practice of medicine have existed, physicians have been obliged to enforce them, often at the cost of much opprobrium and pecuniary sacrifice, or else the laws have been a dead letter on the statute book. This is the reason why many excellent men in the profession are indifferent; they acknowledge that such legislation would be just and may even be demanded, but they do not desire to be placed in the attitude of seeming to make requests for legislative enactments to benefit themselves. "If," they rightly say, "the medical profession cannot stand on its own merits, it has no claim whatever even to ordinary respect." They recognize the fact that one part of their duty is to protect the people from quackery, but they deprecate doing this by methods which will certainly lead to a misinterpretation of motive.

A writer in the *Medical Record*, disgusted with the working of the law in New York, has well emphasized this point of view: "Practically speaking," he says, "the people are not prepared to appreciate our motives, and will never be till they are sufficiently educated to draw the line between quackery and legitimate medicine. [Alas, if we must fold our hands until then, we shall have to wait until their spiritual leaders cease to give certificates endorsing quackery!] When that time comes, there will be no difficulty in having suitable laws passed, and the people will themselves take the proper steps to punish any offenders. [In such a time there will be few quacks to punish, culture soil will be unpropitious.] If we must legislate at all, let it be in the direction of improving ourselves. There is a great deal that may be done in this direction. Our college regulations can be made more stringent, our standard of preliminary requirements raised, our terms of study extended, and, in fact, the whole system of medical education can be elevated. By limiting our efforts to such reforms we can at least prevent quacks and incompetent persons from coming into our ranks, and this will be a benefit and a blessing to society."

E. P. H.

THE PRODUCTION OF VACCINE VIRUS.

ROXBURY, May 5, 1894.

MR. EDITOR:—Permit me to say a few words in regard to the Report under the above heading in last week's JOURNAL. As I supply a large number of the physicians and cities throughout the country with vaccine, the matter is of importance to me. The committee making the report did not come to me, nor visit my vaccine establishment, and the first intimation I had of any such committee was when I heard their report read at the Norfolk District Society. I was brought up from boyhood, by my father, in a most careful training and course of study regarding the whole subject of vaccination, and can fairly claim a very different familiarity with the whole matter than any of the other persons referred to in the report. The "Martin Establishment" referred to, was the old establishment at Brookline, which my brother carried on until his death. The committee obtained their information there from a former employee of my brother, who was not a physician.

Neither my father nor myself would ever countenance anything but the most scrupulous care in every detail in the management of vaccine production, and the reputation our virus has enjoyed uninterruptedly for twenty-five years, shows what that care has been. Moreover, the propagation of vaccine virus by any one but a thoroughly educated regular physician is bound to lead to trouble and disaster—to the patients, at any rate, if not to the producers.

I must ask the profession to in no way confound my establishment with those mentioned in the report.

Very truly yours, FRANCIS C. MARTIN, M.D.

METEOROLOGICAL RECORD.

For the week ending April 28th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Deaths reported 2,611: under five years of age 937; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fever) 836; acute lung diseases 451, consumption 312, diphtheria and croup 141, diarrhoeal diseases 42, measles 38, scarlet fever 33, typhoid fever 23, whooping-cough 22, erysipelas 13, cerebro-spinal meningitis 12, small-pox 9, malarial fever 2.

From scarlet fever New York 10, Brooklyn 8, Philadelphia, 6, Boston and Pittsburg 2 each, Cincinnati, Nashville, Lowell, Cambridge and New Bedford 1 each. From typhoid fever Philadelphia 6, Boston 4, Washington, Cincinnati and Milwaukee 2 each, New York, Brooklyn, Nashville, Lowell, Lynn, New Bedford and Taunton 1 each. From whooping-cough New York 6, Philadelphia and Pittsburg 3 each, Boston and Cambridge 2 each, Washington, Milwaukee, Charlestown and Lynn 1 each. From erysipelas New York 7, Philadelphia 3, Brooklyn,

Boston and Milwaukee 1 each. From cerebro-spinal meningitis New York 4, Cleveland and Somerville 2 each, Philadelphia, Washington, Lynn and Salem 1 each. From small-pox New York and Brooklyn 4 each, Boston 1.

In the thirty-three greater towns of England and Wales with an estimated population of 10,468,442, for the week ending April 14th, the death-rate was 19.3. Deaths reported 3,877: acute diseases of the respiratory organs (London) 304, whooping-cough 142, measles 87, diphtheria 72, scarlet fever 50, diarrhoea 38, fever 33, small-pox (Birmingham 3, West Ham 2, Portsmouth 1) 6.

The death-rates ranged from 11.6 in Huddersfield to 31.9 in Wolverhampton; Birmingham 21.8, Bradford 17.9, Croydon 12.6, Halifax 17.4, Leeds 16.2, Liverpool 24.7, London 19.3, Manchester 22.8, Nottingham 18.4, Portsmouth 15.6, Sheffield 18.6.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 28, 1894, TO MAY 4, 1894.

Leave of absence for two months, to take effect on or about May 1, 1894, with permission to go beyond sea, is granted MAJOR CALVIN DEWITT, surgeon.

CAPTAIN C. N. BERKELEY MACAULEY, assistant surgeon, is relieved from duty at the U. S. Military Academy, West Point, New York, and ordered to duty at Fort Wingate, New Mexico, relieving MAJOR WASHINGTON MATTHEWS, surgeon, who, on being thus relieved, will repair to Washington, D. C., and report in person to the surgeon-general for temporary duty in his office.

So much of paragraph 13, S. O. 72, A. G. O., April 3, 1894, as assigns MAJOR PETER J. A. CLARY, surgeon, to duty at Fort Wingate, New Mexico, is revoked.

Leave of absence for two months, on surgeon's certificate of disability, to take effect when his services can be spared, with permission to leave the Department of the Colorado, is granted CAPTAIN EDWARD EVERTS, assistant surgeon.

ASSOCIATION OF AMERICAN PHYSICIANS, AND CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

The ninth annual meeting of the Association of American Physicians will be held in connection with the third Congress of American Physicians and Surgeons at Washington, D. C., May 29, 30 and 31, and June 1, 1894.

The Association will hold its meetings in Hall No. 2, Columbian University, corner of Fifteenth and H Streets. The sessions of the Association will be held in the morning, between the hours of ten and one, and those of the Congress will be held in the afternoon, between the hours of two and six.

The following is the programme of the meetings of the Association:

Tuesday.—1. "President's Address." Reginald H. Fitz, Boston. 2. General Business, Reports, etc. 3. "The Treatment of Certain Symptoms of Croupous Pneumonia, particularly in Adults." Beverly Robinson, New York. 4. "A Treatment of Typhoid Fever." Samuel A. Fisk, Denver. 5. "Six Cases of Traumatic Headache." C. F. Folsom, Boston. 6. "Clinical Report of Two Cases of Raynaud's Disease." Frederick P. Henry, Philadelphia. 7. "Dr. S. C. Martin's Researches on the Bacteria of Vaccine." Harold C. Ernst, Boston.

Wednesday.—8. "Modification, Temporary and Permanent, of Physiological Characters of Bacteria in Mixed Cultures." Theobald Smith, Washington. 9. "The Effect of Various Metals on the Growth of Pathogenic Bacteria." Meade Bolton, Baltimore. 10. "Note on the Observation of Malarial Organisms in Connection with Typhoid Fever." W. Gilman Thompson, New York. 11. "Experiments in Artificial Melanosis." George Dock, Ann Arbor. 12. "Stomatitis Neurotica." A. Jacobi, New York. 13. "Tetany in America." J. P. Crozer Griffith, Philadelphia.

Thursday.—14. "Lead Palsy in Children." Wharton Sinkler, Philadelphia. 15. "A Study of the Temperature in Cerebral Apoplexy." Charles L. Dana, New York. 16. "The Mild Character and Diminished Prevalence of Syphilis and the Infrequency of Visceral Syphilis." John H. Muzzey, Philadelphia. 17. "Some Remarks on the Significance of Albumin and Casts, especially in those past Middle Life." Frederick C. Shattuck, Boston. 18. "Experimental Phthisis in the Rabbit with Formation of Cavities: A Demonstration." T. M. Prudden, New York. 19. "A Report of the Ultimate Results Obtained on Experimental Eye Tuberculosis by Tuberculin Treatment and Anti-Tubercular Inoculation." E. L. Trudeau, Saranac Lake.

Friday.—20. "Some of the Chemical and Bacteriological Characteristics of Milk." Thomas M. Rotch, Boston. 21. "The Chemical Products of the Anaerobic Putrefaction of Pancreatic and Hepatic Tissues, and their Effects upon the Tests for Morphia." Victor C. Vaughan, Ann Arbor. 22. "Gastro Enteric Rheumatism." H. M. Lyman, Chicago. 23. "A Case

of Osteomalacia." George Dock, Ann Arbor. 24. "A Case of Mitral Stenosis, with great Hypertrophy of the Right Ventricle: Death from Hæmoptysis." A. McPhedran, Toronto. 25. "A Case of Calculous Pyelitis with Invasion by the Bacillus Lactis Aerogenes." J. H. Musser, Philadelphia. 26. Concluding Business.

The following subjects will be considered by the Congress: "Morphology as a Factor in the Study of Disease." "Sewer Gas." "The Distribution and Control of Leprosy in the United States." "Nephritis in its Surgical Aspects." "The Conservative Surgery of the Female Pelvic Organs." "The Surgery of the Accessory Sinuses of the Nose." "The Influence of Infectious Processes on the Nervous System."

On Wednesday there will be a Dinner to the guests of the Congress at the Arlington Hotel; and on Thursday Evening Dr. Alfred L. Loomis, President of the Congress, will deliver an Address on "The Influence of Animal Experimentation on Medical Science," which will be followed by a Reception.

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—A regular meeting of the Society will be held at the Massachusetts Institute of Technology, Walker Building, corner of Clarendon Street, on Monday evening, May 14th, at quarter past eight o'clock, precisely.

Dr. W. M. Conant will read a paper on "College Athletics." The discussion will be opened by Dr. H. P. Walcott, President Eliot, General Walker, Mayor Bancroft and Dr. W. A. Brooks. Physicians interested in the subject are cordially invited to be present.

JOHN T. BOWEN, M.D., Secretary.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT.—The Section for Clinical Medicine, Pathology and Hygiene will meet at 19 Boylston Place, on Wednesday, May 16th, at 8 o'clock.

Papers: Dr. H. C. Vickery, "Fatal Vomiting without Discoverable Cause."

Dr. J. Bergen Ogden, "Three Cases of Chronic Bright's Disease of Different Types."

F. C. SHATTUCK, M.D., Chairman.

HENRY JACKSON, M.D., Secretary.

TWENTY-FIRST NATIONAL CONFERENCE OF CHARITIES AND CORRECTION will be held at Nashville, Tenn., beginning May 23d and closing Monday, May 28th.

The membership of the Conference includes members of State Boards of Charities, delegates from Charity Organization societies, officers of public and private charitable and correctional institutions, official delegates appointed by the Governors of States, and all other persons directly or indirectly connected with charitable work. All persons included under this general description are invited to attend the Conference, and the boards in charge of charitable or correctional institutions, public or private, are invited to send delegates.

The Conference is non-sectarian and non-political, and its aims are purely scientific and philanthropic.

L. C. STORRS, President, Lansing, Mich.

A. O. WRIGHT, Secretary, Madison, Wis.

JOHN M. GLENN, Treasurer, Baltimore, Md.

RECENT DEATHS.

DR. JULES ARNOLD, Professor of Hygiene in the Faculty of Medicine at Lille and one of the Army Medical Inspectors of France, died recently, aged sixty-three years. He was an army surgeon during the Crimean War and in 1862 was professor of military hygiene at Val de Grâce.

BOOKS AND PAMPHLETS RECEIVED.

The Therapeutic Uses of the Salts of Cesium and Rubidium. By Theodore W. Schaefer, M.D., of Kansas City, Mo. Reprint. 1894.

Proceedings of the Inaugural Meeting of the Medical Association of India held at Calcutta on February 21, 1894. Reprint. 1894.

Further Remarks on the Occurrence of a Form of Non-Albuminous Nephritis other than Typical Fibroid Kidney. By D. D. Stewart, M.D. Reprint. 1894.

The Medical Annual and Practitioners' Index; a Work of Reference for Medical Practitioners. Twelfth year. Bristol: John Wright & Co. 1894.

Thirty-third Annual Report of the Cincinnati Hospital to the Mayor of Cincinnati for the Fiscal Year ending December 31, 1893. Frank W. Hendley, M.D., Superintendent. Cincinnati. 1894.

Traitement des Rétrécissements par l'électrolyse linéaire. Par le Dr. J. A. Forb, Ancien Interne des Hôpitaux, Professeur libre d'anatomie à l'Ecole Pratique de la Faculté de Médecine de Paris. Paris: G. Masson. 1894.

Address.**ANNUAL ADDRESS**

DELIVERED AT THE OPENING OF THE TWENTY-FOURTH ANNUAL MEETING OF THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA, APRIL, 1894.¹

BY C. G. KENYON, M.D., PRESIDENT, SAN FRANCISCO, CAL.

LADIES AND GENTLEMEN, MEMBERS OF THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA:—The Architect of the Universe has, with lavish hand, bestowed his benefits upon our State and upon the various sections of the State that we severally represent. We have a soil which, under the touch of the husbandman and the influence of an unequalled and varied climate, brings forth in abundance the fruits and products alike of the temperate and of the tropical zone. And where, in all the broad domain of our sunny California, do we find a section more richly blest than this Santa Clara Valley, enclosed about with mountain side, bedecked throughout its entire length and breadth with happy homes, and in its centre seated the beautiful Garden City, lovely San José, famed throughout our State for its wealth, its culture, and its learning? Our profession is ably represented in this hall by a large delegation of the resident physicians, who have ever kept abreast with the general onward march of the times, no feature of which is more marked than the great strides taken by our science in the triumphal procession.

Surrounded as I am by so many who have become eminent in our profession, I can hardly flatter myself that many here expect to learn anything new from a president's annual address, and it is more than probable that if any did their expectation would be disappointed. But an annual address is a time-honored custom, and it seems to me that its office is less to impart information than to give public expression to, and, perhaps, to afford opportunity for, more general discussion of ideas, which, no doubt, have often suggested themselves to many individual members. I propose to mention briefly a few matters, which, I think, concern the good and the welfare of our Society, claiming for myself no merit as an original discoverer, and leaving it to this convention to determine for itself to what extent, if any, the suggestions now presented are acceptable to the majority of its members.

It is quite the fashion, in addresses by medical men, for the speaker to lament, in a pessimistic mood, the deplorable lack of higher education and general professional attainments in the profession in our own country, as compared with the standard in other older, and, especially, European countries. To these jeremiads I desire to offer my humble protest. While my voice will always be uplifted in favor of the best type of manhood, and the highest standard of attainments, as pre-necessary qualifications for those who would assume the honorable title of M.D., yet I am pleased to call your attention to the general activity and earnestness displayed by the profession within the influence of this Society, and I venture the assertion that, striking a general average of the profession in California, no body of men can be found under the sun better informed and more capable as a whole than we have here. In proof of this assertion, I refer you to the high standard adopted by our medical schools, the vast amount of

medical literature, local and foreign, received and supported by our profession; the prevalent custom among our young men to go abroad to further qualify themselves, in wider fields, for professional work; and the general activity exhibited in our local and State organizations.

That this Society is an important, and may be made to become a more important, factor in maintaining this standard of excellence, is a statement which I need hardly make here. Your presence as members of this organization, many of you coming great distances from your homes to attend this convention, testifies to your appreciation of the fact. This being so, is it not well that we should consider whether by any, and if by any, by what means we may best extend and widen this Society's sphere of acknowledged usefulness? I propose to offer for your consideration some changes in the constitution and by-laws of this Society, with the end in view of increasing our membership, our working capacity, and our power of advancement of the profession within this State.

We are pleased to call this organization "The Medical Society of the State of California," a very high-sounding and comprehensive title. But when we consider the fact that out of 2,700 licensed practitioners of regular medicine in the State our membership consists of some 360 only, it becomes apparent how short we fall of fulfilling the high and important mission which our title, and our objects as declared in our constitution, would indicate.

As I have before intimated, we may assume, without argument, that membership in this Society is beneficial to the members and to the advancement of our science. It becomes, then, our duty to consider the proper and best course to pursue to extend those benefits to the utmost limits. That we have been only partly successful under our present plan of organization, is too patent to require discussion. Having given this matter much thought and consideration, I desire to bring before you some suggestions, which, if they are found worthy of your approval, will, I believe, increase our membership and extend our field of usefulness.

[These suggestions included a recommendation of a reduction of annual dues, the abolition of enforced continuous membership in the local society, and the establishment of a quarterly bulletin, containing such information and contributions as the Committee on Publication might deem most worthy of space.]

Overcrowding in the Profession.—As before stated, in this State we have about 2,700 practitioners of medicine and surgery, graduates of regular medicine and licentiates of its Board of Examiners, without counting several hundred licentiates of homoeopathy and eclecticism. This vast number has as a field of labor a State with a population of 1,500,000, which by a simple process of division shows one doctor to every 500 of population. To say that our profession is overcrowded expresses a fact too patent to admit of discussion. As an equal distribution leaves only this small ratio for a clientele, what must be the portion left to some of the profession, when we find leading physicians who enjoy the patronage of thousands? The obvious tendency of this overcrowding, it is to be feared, is to lower the standard of professional conduct among regularly educated and licensed practitioners.

We have also to consider, in addition to this unpleasant picture of a small army of medical men striving for existence in a limited field, a host of quacks of

¹ The following extracts from Dr. Kenyon's Address are from advance sheets of the Occidental Medical Times.

various kinds and degrees, who, like the camp-followers that hung about Sherman's army on its famous "march to the sea," are ever on the alert to pick up choice bits of forage and sustenance that should fall to the lot of the regular soldier, whose mess must suffer to the extent of the irregular depredations. Here we have a somewhat homely, but, I think, pertinent illustration of the situation.

But it is easier to depict this unfortunate condition of affairs than to recommend measures of adequate relief. The following suggestions, however, seem to me to be appropriate: We should no longer hold out to intending students of medicine alluring pictures of the excellence of this State as a field for practice. Until the time comes, if ever, when there shall be a more reasonable proportion between practitioners and patients, it is bound to be a question of the survival of the fittest, and meanwhile, only moderate encouragement should be given to students, and to those only who, by more than average ability, and by a high degree of preliminary education, give promise that at the end of their course of medical study they will come into the field fully equipped and qualified to engage in what, at best, must be a struggle for existence.

Again, it is well known that medical men cannot go from this to other countries on the American continent or in Europe and assume the practice of medicine until after a strict examination there, and the securing of a certificate in accordance with the laws of the government under which they may choose to settle. We, however, with that excess of liberality found only in this land of refuge for all people, and of the refuse of many, the "Heathen Chinee" not excepted, receive all comers with open arms, welcome them to share our meagre loaf, and our people patronize them to the exclusion, frequently, of those to the manor born, and at least equally qualified by natural ability and education. The halo of mystery and greatness which hovers about a foreign doctor seems to have a peculiar fascination for the American mind, and our imported frater is not always too modest to use this peculiar bent for all the advantage it may bring him.

Hospital Clinics and Free Dispensaries.—The influence of hospitals, dispensaries, college clinics, etc., upon the general practice, has been considerably discussed of late. That the increase of such institutions is having a marked effect upon the field of labor of the general practitioner, especially in metropolitan centres, needs no argument. That the best service in all branches of practice is freely given in the several free dispensaries or clinics in San Francisco, while the excellent hospitals offer to the afflicted at small cost, a haven where capital operations are performed daily by skilled operators under the advantageous surroundings of the most modern methods, and that the tendency of all this is to diminish the field for work for the less favored who constitute the larger portion of the profession, is also an accepted fact.

The young man entering the profession, however well fitted by thorough training, supplemented by hospital experience in the best institutions in the world, finds but a limited scope for his talents, if he be not one of the fortunate few holding positions in public or private institutions that bring to them abundance of material for the exercise of their acquired skill. He must content himself with sitting patiently in his office, waiting for business that is long in coming or that may never come. The claim that suffering humanity

alone should be considered in a question like this—that better service can be rendered in hospitals under aseptic conditions—is no doubt to a certain extent just, and the general practitioner, recognizing this and frequently ready to sacrifice his own interests to that of his patient, is often quite ready to recommend a sufferer to the hospital. He even goes there himself, and, with his hands in his pockets, or behind him (as a precaution against the conveyance of germs from his polluted person) watches his more fortunate brother, made clean by aseptic ablutions and bedecked in a clean apron, do his work. Then he goes away filled with a satisfying consciousness of having served his patient well, but with an empty pocketbook and a lack of that practical experience which properly belongs to him. He is little benefited even by observing the operation; it is one that he has probably seen and taken part in many times before.

The practice thus outlined may be best for humanity, but it results in making experts of one class, while the great mass of medical men are dropping into mediocrity and losing the incentive to improve their acquired ability for lack of opportunity to exercise it. In the rapid growth of this dispensary system, our medical men are themselves the most active agents. I speak only of dispensaries under the management of regular practitioners, such as college clinics, dispensaries, etc., under the auspices of colleges or associations, conducted in the name of charity, sweet charity, under whose banner skilled services, medical and surgical, are free as water. Various means of advertising, all strictly legitimate, are resorted to to encourage the afflicted to seek professional aid in these free centres of practice, while around the corner—many corners—are seated in their offices well-skilled medical men waiting in vain for their fair share of business, which, if an equal division could be made, would leave them a clientele of less than 600.

If all who availed themselves of this gratuitous system of service were really entitled to it, there would be less cause for complaint, but it is well known that many who can well afford to employ a general practitioner, now resort to these institutions whose real object is, or should be, to dispense medical and surgical aid to the poor and needy.

It is well, occasionally, to get down from the high plane from which this subject is frequently treated. Medical men are prone to soar to a high level. We speak of our remuneration as an "honorarium," yet after all we are only a class of bread-winners in common with others of our fellow-beings—an honorable class—striving to earn a livelihood by the pursuit of our profession. The practice of medicine is our business; and most of us are, or ought to be, supporting and educating families out of the legitimate financial proceeds of our business. If we could all become suddenly alive to this important fact, and could at once proceed like a band of brothers to a fair and equitable distribution of work and its proceeds, then, indeed, should we see a medical millennium; but this is, of course, a chimera. No medical body, much less an individual, is likely to change the trend of current events. Some good, however, may be attained by directing our attention, for a moment, to these problems, and to their bearing upon the welfare of the medical world.

Feticide.—Feticide, infanticide, and methods of preventing pregnancy, are subjects tabooed in polite society, and even in a body of medical men, they gen-

erally receive little or no attention. The evil, however, is becoming one of such magnitude, so far reaching in its effects, that I feel it incumbent upon me, as the temporary exponent of this Society, to give free and bold expression to the abhorrence in which all reputable practitioners must hold the various methods of prevention of child-bearing, and the very frequent procurement of abortions, as tending to deteriorate the moral tone of society, debauch public sentiment and shake the foundations of society — the domestic relation, the home. That regular medical men and women, such as constitute my hearers, do not participate in these disreputable practices, is a position I desire in the strongest manner possible to maintain, but that in the popular mind we escape the odium attached to them, is, unfortunately, not susceptible of proof. It is too true that the upright regular practitioner shares with the charlatan or advertising quack whatever popular opprobrium these nefarious secret practices receive. With the great public a "doctor" is a doctor. Reputable medical men and women who indignantly dismiss a patient who applies to them for such a purpose, are frequently met with the remark, "Why, I thought all doctors did it." And so the few cases which are brought to public notice through the death of the unfortunate woman at the hands of some scoundrel man or woman, calling himself or herself "doctor," bring odium on our profession, and usually without remonstrance on our part.

It is high time the regular profession should take a stand and clear its skirts of the opprobrium. It is our duty, both by precept and practice, to establish the fact in the minds of the public that we have no sympathy with criminal business, or with the criminals who practise it. When that point is attained we may reasonably hope for some abatement of the evil. It is a lamentable fact that a large proportion of the male population believes that this nefarious business is practised by almost all medical men, and while that popular impression prevails juries will not convict, even in flagrant cases. It has been demonstrated in recent trials in San Francisco that a man who has openly practised a criminal business for many years, who drags his unfortunate victim from his own infamous den and places her upon a car to die a few hours later in transportation, may go scot free.

The public prints are frequently filled with the nauseating details of some of these cases; many, we know, are hushed up, while the culprits are left unmolested to continue their unlawful practices. One solitary conviction stands out in bold relief, and this, in the present perverted state of public sentiment, seems somewhat of a shock. "Why should not this man have gone free when everybody is doing it?" asks many a good citizen; and, in fact, it is doubtful whether the conviction in that case was as much a mark of the jury's disapprobation of the crime committed on the living body as it was of its horror of the barbarous mutilation of the senseless corpse.

The prevention of these unlawful practices is ultimately a matter for the people and for the courts. The present law seems inadequate, and public sentiment does not seem to be strong enough to devise proper remedies. Does it not behoove us, therefore, to do what we may towards stemming this tide of immorality? The regular profession should take no unequivocal ground, but should, in season and out of season, contend against the continuance of these prac-

tices, and strive to educate the people to a higher plane of morality. If we do not do so, the fair eulogium of our time-honored profession will continue to suffer the opprobrium brought upon it by the practices of a disreputable class with whom we have no connection by sympathy or association.

It should be the duty of the physician not only to frown down these practices, but also to use the greatest care, lest by a word or hint he carelessly direct an applicant for criminal relief to one of these dens of infamy. It will not do to say to an unfortunate suppliant that such and such persons have the reputation of doing these things; we cannot afford to become even indirectly agents, or "steerers," if I may use the term, for these people, simply as an easy method of getting rid of an undesirable patron. No; the proper thing to do is to answer these deluded women in a manner short and sharp, "We have nothing to do with such cases, and do not know of any one who practises criminal business."

The statutes in reference to evidence in cases of criminal abortion should be modified, so that evidence of the only other witness to the crime beside the operator might be available to prove guilt.

Embalming. — The disposition of the bodies of the dead, owing to the growing sentiment in favor of cremation, occupies a prominent place in the minds of the medical profession. For sanitary reasons, the profession is almost a unit in favor of incineration. One objection to this plan for disposing of the dead, however, from a medico-legal point of view, is that by it all evidence of the cause of death disappears, if we may be allowed to use the expression, in smoke.

While speaking on this point, it is pertinent to refer to a custom which is becoming established among undertakers, and which should be stopped. I refer to the injection of the body immediately after death with embalming or preservative fluids, a proceeding in this climate wholly unnecessary. It is a trick that is being too successfully worked by undertakers, for their own profit, on the friends of the deceased. Thoughts of economy, much less of parsimony, seldom enter the minds of the grief-stricken family, and so when the shrewd undertaker, with thoughts of his coming bill, suggests, "Of course you wish the body embalmed?" the answer is rarely in the negative. But I refer to the matter for the more important reason that the corpse, after being subjected to this so-called embalming process, is saturated with mineral poison, obliterating every evidence of crime, if any exists. I recommend that the Committee on Legislation endeavor to have a law passed prohibiting the use of any embalming process until after permission has been granted by a coroner or other proper officer.

The Code of Ethics of the American Medical Association. — The Code of Medical Ethics adopted by the American Medical Association and by the Medical Society of the State of California has been the Magna Charta of the profession throughout the United States for many years, and has seemed ample for the purpose for which it was designed — the regulation of the conduct of members of the profession. However, the development of specialties and the overweening desire of some of the leading medical men in New York City to enlarge the scope of their practice has of late caused a departure from some of our long-established principles, and the adoption of a modified Code in the State of New York.

At a recent meeting of the American Medical Association a committee was appointed to revise the Code, and the matter will undoubtedly be brought up at the meeting to be held this year in San Francisco. I do not propose to attempt to influence the action of members of this Society in this matter, but I urge you all to study the Code thoroughly, and if, after mature reflection, that Code, which has stood the test of time, meets your approbation, I would be glad to see the profession in California loyal to its tenets. The medical profession in the United States has done well under the present Code of Ethics; its history is one upon which we can reflect with pride. Under this Code, ample scope has been allowed for the progressive members to make brilliant records by the introduction of new methods in the practice of medicine and surgery, which have redounded to the credit of the medical world.

Quarantine and Cholera.—At the time of the twenty-third annual meeting of this Society in 1893, Asiatic cholera threatened to invade England and the United States. That we were not visited by the dreaded scourge is due to the enlightened and efficient measures adopted to arrest it; and although infected ships arrived off New York, the barriers proved effectual. The loss of human life, not to speak of the damage to the business interests of the country which an epidemic of Asiatic cholera would have caused, cannot be measured. Such an invasion would have demoralized all traffic, have paralyzed our commerce, and have proved the utter ruin of the great Columbian Exposition. The success attending the measures adopted to avert this disaster is the highest testimony to the efficacy and value of modern sanitary science.

Lecture.

URINARY DIAGNOSIS.¹

BY EDWARD S. WOOD, M.D.,
Professor of Chemistry, Harvard Medical School.

LECTURE I.

I do not expect to do full justice to the subject of "Urinary Diagnosis" in the two hours that are allotted to these lectures; but I will endeavor to condense the material in such a way as to include most of the important changes which occur in the urine and which are of diagnostic importance.

In the early history of medicine we learn that the urine was examined for diagnostic purposes, and this examination was of assistance in the diagnosis and prognosis and in deciding as to the treatment of different diseases. It so happens that I have in my possession a work that was published more than three centuries ago, which is devoted entirely to the examination of the urine. In more recent times, after the chemical composition of the urine became better understood, and yet before the microscope was fully developed, certain changes were detected in the chemical composition of the urine, which were considered of so much importance that they received a special name, and these names were generally used as indicating certain diseases. They are still in use to-day. I refer to the terms albuminuria, glycosuria, hæmaturia, oxaluria, and cysti-

nuria; these all have a distinct meaning, and the changes which they represent are of very great importance. Their use is continued at the present time, as it should be, but their meaning is very properly so restricted as to indicate simply a symptom, possibly of many different pathological conditions. A great many of us in the present generation can remember very distinctly the time when the terms albuminuria and Bright's disease of the kidney were considered synonymous. Of course, we all now know that the term albuminuria means simply the presence of albumin in the urine, and that it may occur in a great many diseases. The term is by no means synonymous with Bright's disease, and in the majority of cases of albuminuria there is no organic disease of the kidney. The study of this symptom—albuminuria—I shall defer until later when we consider the character of the urine in the various kidney diseases.

Glycosuria, which used to be considered as synonymous with diabetes mellitus, means simply the presence of grape sugar in the urine. We now know that there are other conditions which are characterized by the presence of grape sugar in the urine. It is of very great importance to be able to distinguish, from the examination of the urine, between cases of diabetes and cases of simple glycosuria. In order to do that, we must take into consideration several other important diagnostic features. One is, as to whether the grape sugar is present in the urine permanently or temporarily. In diabetes, if the patient remains untreated, grape sugar is present in the urine in considerable quantity and for a long time, whereas, in glycosuria due to other causes, the sugar is present in the urine, usually, in small quantity and temporarily. The general character of the urine in diabetes I need only allude to. The daily quantity is large; in extreme cases from six to eight quarts in twenty-four hours. It is of pale color, high specific gravity, and contains a large amount of grape sugar, varying from two or two and one-half to nine or ten per cent. of the total weight of urine, so that a patient suffering from regular diabetes may eliminate two or three pounds of grape sugar in twenty-four hours. But, you will observe in studying the urine in many cases of diabetes, that there are two distinct classes of cases, in both of which the daily quantity of urine and of sugar may be very large, but if the urine passed at different times of day be examined separately, it will be found that in some cases nearly all of the sugar eliminated is contained in the urine passed after eating, while the fasting urine contains but a very small percentage of sugar; whereas, in other cases, there is but little if any difference in the percentage of sugar in the urine secreted at these two different times. Clinically, these two kinds of cases are quite distinct. Those cases in which the fasting urine contains about as large a percentage of sugar as the after-meal urine, generally resist all treatment, pursue a fairly rapid course, and terminate fatally in a comparatively short period of time. Whereas, those cases in which the fasting urine contains but a very small percentage of sugar, the patient may be so much relieved by treatment that the grape sugar may disappear from the urine entirely, although he may have had glycosuria for several years. Cases of temporary glycosuria are of comparatively little consequence from a diagnostic point of view, since the glycosuria is secondary to some disease, the nature of which is generally easily recognized, as in some cases of apoplexy,

¹ Evening Lecture delivered at the Harvard Medical School, February 21, 1894.

head injuries etc. In these cases the quantity of urine is not increased as much as in either of the forms of diabetes.

The term hæmaturia, which has been in use for many years, indicates, as its name implies, the presence of blood in the urine. In recent years, however, this term has been subdivided according as the urine contains *all* of the constituents of the blood, both globules and serum, hæmaturia, or only the coloring matter, hæmoglobinuria. The distinction between these two conditions is, that in hæmaturia, which is due to hæmorrhage from some portion of the kidneys or urinary passages, we find upon examination of the urine more or less of the blood pigment, partly decomposed or not, in solution in the urine, and, upon microscopical examination of the sediment, we see a large number of blood corpuscles, so that we have all of the elements of blood present in the urine. In cases of hæmoglobinuria, on the other hand, we find only blood pigment in the urine. The blood pigment is set free from the red corpuscles within the blood-vessels and not in the urinary passages, and it is simply eliminated from the blood by the kidneys. Upon microscopic examination of the urinary sediment, in cases of hæmoglobinuria, we do not see any blood corpuscles in the sediment, and we have, therefore, only the coloring matter of the blood in the urine without the blood corpuscles. Hæmaturia means simply hæmorrhage from the urinary or genito-urinary passages, while hæmoglobinuria means blood pigment in the urine and it is a symptom of a disease of the blood and not of the kidneys or urinary passages.

Oxaluria is a term which signifies the presence of calcic oxalate in the urine and this condition is sometimes of diagnostic importance. It is detected by seeing the calcic oxalate crystals in the sediment upon microscopic examination. This means that oxalic acid has been formed in the economy, or that it has been taken into the economy with some article of food or drink. Its importance depends entirely upon the quantity which appears in the urine and upon its permanency. No doubt all of us have occasionally a temporary oxaluria due to some article of food or drink, which contains oxalic acid. The drug rhubarb, as well as the garden rhubarb, will impart a certain amount of oxalic acid to the economy. If calcic oxalate is found in considerable quantity in the urine, we are pretty sure, also, to find evidence in the sediment, of the local action of the sharp calcic oxalate crystals upon the lining membrane of the renal tubules. They scratch more or less, and cause mechanical irritation of the kidneys, the evidence of which may be detected in the sediment together with a number of the crystals. If the oxaluria is long continued, there is always danger that a mass of the crystals may become aggregated together with fibrin or mucus, and form an oxalate concretion. You all know how serious are the effects produced by the so-called mulberry calculus, which is composed of calcic oxalate; its rough surface produces so much inflammation and hæmorrhage that the mulberry calculus is almost invariably dark brown or black in color owing to the decomposed blood pigment which is present in its structure.

Chyluria is one of the old terms which comes more nearly meaning a disease than most of the other terms applied to certain changes in the composition of the urine. The term chyluria means simply the presence of chyle in the urine. That can only occur in case

there is some connection between the lymphatics and the urinary passages, and, we know now, that the disease of the lymphatics is caused by the presence in them of a parasite, the *filaria sanguinis hominis*. Chylous urine is a milky-looking urine, which contains fat in so finely divided a form that it never separates, if the urine is prevented from decomposing. The fat neither settles as a sediment, nor rises to the surface to form a film. In many cases of chyluria we may have this peculiar appearance present in the urine only at certain times of day, or it may be present for a period of several weeks and then disappear, only to recur again at some later period. This specimen of chylous urine, which I have here, was passed by one of the medical students, a native of Cuba, and when perfectly fresh was hermetically sealed in this test-tube, which has not been turned upside down since the urine was placed in it in 1876. Yet, as you see, the milky appearance is as evident in the upper as in the lower layers of the fluid. The fat is so finely divided that it cannot be detected by examination even with the highest powers of the microscope in the shape of oil globules. This fact enables us to distinguish readily between chylous urine and urine to which milk has been added. Milk is sometimes added to the urine by hysterical patients for the purpose of deception. If the urine contains milk a drop of the milky fluid examined under the microscope is seen to contain the oil globules of the milk. Another means of distinguishing these two conditions, is to shake a little of the milky urine in a test-tube with ether. When chylous urine is shaken with ether the fat is readily dissolved by the ether, and when the ether separates from the urine, it is seen that the latter fluid has lost its milky appearance. Ether will not separate the fat from urine to which milk has been added.

Cystinuria. The diagnosis of cystinuria is made only by recognizing on microscopic examination the peculiar crystals of cystin. These crystals are colorless, hexagonal plates, readily soluble in ammonia and the mineral acids, but insoluble in acetic acid. It contains a very large percentage of sulphur 26 per cent., and is probably due to some faulty metabolism by which the sulphur derived from the albuminoids is eliminated in the form of cystin instead of in the form of taurine of the bile. The recognition of cystin is of importance only as enabling us to distinguish between that form of urinary deposit and others in cases of urinary concretions, in the examination of the urine for diagnostic purposes.

Alkaptonuria. This is another condition of the urine which has received a special name, and I did not intend to mention it all, since I did not consider it of sufficient importance on account of its great rarity. It is so rare that I have never seen a specimen until the present week. This condition of the urine is of greater importance to the life insurance examiner than to the general practitioner, on account of the danger of mistaking a case of alkaptonuria for one of diabetes mellitus. The so-called alkapton, which the urine contains in this condition, may be one of several substances which are powerful reducing agents when in alkaline solution, so that such a urine responds to some of the tests for a diabetic urine, particularly the Heller and Trommer tests, and the test with Fehling solution. A urine containing alkapton is usually normal in color when passed, but after exposure to the air it becomes dark brown in color like that of a carbolic-acid urine.

The quantity in the twenty-four hours is apt to be diminished rather than increased. If rendered alkaline with sodic hydrate and shaken in a test-tube, it absorbs the oxygen from the air in the upper part of the tube, and becomes dark brown in color, rapidly as you see, and at the same time it creates a partial vacuum in the test-tube, so that if the tube be inverted under water, an amount of water equivalent to the volume of oxygen absorbed will be sucked into the test-tube. Some specimens will absorb as much as four-fifths of their volume of oxygen. A urine containing alkapton may be readily distinguished from one containing grape sugar by the following properties: it becomes dark brown in color slowly on exposure to the air and very rapidly if rendered alkaline with sodic or potassic hydrate. It does not react to the fermentation test as does diabetic urine. A person whose urine contains alkapton may enjoy perfectly good health, so that such specimens are only seen in those who present themselves to the life insurance examiner, and those who enter a hospital or consult a physician for some disease entirely unconnected with the condition which causes the alkaptonuria.

In the examination of the urine for diagnostic purposes, of the utmost importance is the quantity of urine that is passed in twenty-four hours. It is absolutely essential in making a differential diagnosis between certain forms of kidney disease, and it is also of very great importance to know exactly the quantity of urine that is passed in many other cases than in organic diseases of the kidney. Let me here say that it is never wise to rely upon the statement of the patient in regard to the quantity of urine passed. You will very frequently be told that he or she is passing no more than usual, whereas, they may be passing from two and one-half to three and one-half quarts in the twenty-four hours. You may be told by the patient that he is passing a much larger quantity than usual, and upon measuring it you will find that he is passing a much smaller amount than normal. In all cases where the examination of the urine is essential in making a diagnosis of kidney or other disease, it is in a vast majority of cases essential that the twenty-four hour quantity should be accurately known. In some cases, it is also necessary to know the relative quantity passed in the day and in the night. Recent observations have shown that in one of the most important forms of Bright's disease, the quantity of urine that is passed in the night time far exceeds that which is passed during the day.

The diagnosis very often depends upon knowing not merely the twenty-four hour quantity of urine, but, also, upon knowing how much work the system has been doing, and how much work the kidneys are capable of doing. But the only estimations which are really necessary, in the vast majority of cases, are the estimation of the quantity of urine and the estimation of the principal organic normal solid, urea, which is the final product of the metabolism of the nitrogenous elements of the body. This estimation of the urea is an exceedingly simple matter. I have found this little apparatus of Dr. Squibb's to be by far the simplest and most satisfactory. A full description of the method of performing the operation is given upon the papers that come with the apparatus, and the whole process requires but a few minutes, so that the quantitative estimation of urea is not nearly as difficult as it used to be. The importance of the estimation of the twenty-

four hour quantity of urine is very great; for instance, we have some general diseases which are characterized by a permanent and large increase in the daily quantity of urine. The most common of these are the two forms of diabetes, diabetes mellitus and diabetes insipidus. There is no trouble in making a diagnosis of the former disease, as we have a large quantity of urine with a very high specific gravity due to the presence of grape sugar. But there is difficulty in making a diagnosis of diabetes insipidus, because we have so many other conditions in which the urine has practically the same characteristics, namely, — urine passed in very large quantity in twenty-four hours and of very low specific gravity. In diabetes insipidus where the symptoms resemble very much those of diabetes mellitus, loss of flesh and the wasting of the tissues, the urine is passed in large quantity and of low specific gravity, although if the normal solid matters be estimated, we will find the twenty-four hour quantity increased. The daily amount of urine is from 3,000 to 3,500 c. c. or more, and we will find the urea running up to eighty or ninety, or even one hundred, grammes in twenty-four hours, the normal amount being from 25 to 35 grammes, thus showing a very large increase. The daily quantity of chlorine also reaches from twenty to thirty grammes instead of the normal of nine or ten grammes. Urine of similar general character, large quantity and low specific gravity, we may find in health, and, also, in many nervous affections existing temporarily, but in these cases the twenty-four hour quantity of solid matters will not be increased, but may be diminished.

A small quantity of urine habitually is of less importance from a diagnostic point of view than a large quantity. We are all familiar with most of the existing diseases that are characterized by a small quantity of urine. Some persons in health pass habitually very small quantities of urine, much smaller than they should, so that instead of eliminating 1,500 c. c. (three pints) as they should, the quantity is frequently diminished to 900 or 1,000 c. c. (about two pints) in twenty-four hours, and the specific gravity reaches 1,030 instead of 1,021. This condition, if long continued, may cause irritation of the kidneys. The most common diseases, characterized by an abnormally small quantity of urine, are acute diseases. It is rarely necessary to resort to an examination of the urine in the ordinary febrile cases, but there are some in which the testing of the urine is of a good deal of importance. These are the acute diseases attended with an exudation, as pneumonia, peritonitis, etc. In these diseases, when the effusion is increasing, the chlorine steadily diminishes from the urine until it may entirely disappear, and it reappears with the beginning of the absorption of the exuded fluid; so that in a pneumonia we can determine the exact time at which the absorption of the exudation from the lung tissue begins more accurately by the reappearance of chlorine in the urine than we can by the physical examination. In peritonitis, in addition to the absence of chlorine, the small quantity and the concentration of the urine, we find an enormous increase of the indoxyl. These peculiarities are naturally of greater importance to the urinary examiner, who does not see the patient, than to the visiting physician who does. Therefore, it is often of value to me in order to enable me to distinguish between one kind of fever and another. From a case in which the quantity of urine is habitually below normal, we can, of course, eliminate at once any

disease which is characterized by a constant abnormal increase.

There is one other condition, so far as the quantity is concerned, which I wish to mention briefly, called anuria. That condition is where there is almost no urine passed. Under this head are included those cases in which only three or four ounces are secreted during two or three days, and I have known almost total suppression of urine to last for a longer time, so that only a few ounces may be eliminated in the course of two weeks. We find that condition of almost total suppression of urine in many diseases toward death, in which case, of course, its existence is of really no diagnostic importance. We sometimes see it in cases of acute nephritis, where only a few ounces may be secreted in twenty-four hours. In the last case of severe acute nephritis which I saw, only four ounces of black urine were passed in forty-eight hours.

Where there is an obstruction to the flow of urine through the urinary passages, we may have a condition resembling anuria. This may occur in some surgical cases, as for instance, where there is a tight urethral stricture. There is another condition which is called obstructive suppression, of which I have seen, perhaps, half-a-dozen cases. These are due to the compression of the urinary passages above the urethra so as to permit of only a comparatively small quantity of urine passing into the bladder. A very remarkable case of this kind was reported a few years since by Dr. J. W. Farlow,² in which compression of both ureters was caused by a malignant growth of both Fallopian tubes, and in that way the calibre of both ureters was so much constricted as to be at times completely occluded. At one time a period of twelve days elapsed without any urine being secreted. Obstruction of the ureters by calculi is, perhaps, the most common cause of obstructive suppression. As a general rule, the urine of obstructive suppression is characterized by being passed in small quantities, of very pale color, and very low specific gravity, and you may or may not find evidence of kidney disease by the microscopical examination of the sediment.

THE ACTION OF RATTLESNAKE VENOM UPON THE BACTERICIDAL POWER OF THE BLOOD SERUM.¹

BY CHARLES B. EWING, M.D.,
Medical Department, United States Army.

AN apology would be necessary for introducing a subject of this character, on the present occasion, if it were not that the loss of life from poisonous reptiles has become so great that it calls forth the best effort of not only the military surgeon but of medical men generally, to lessen it.

The mortality in India alone reaches the alarming figure of 20,000 persons annually, hence it was not a strange coincidence that it should have fallen to the lot of the British Medical Service, lead by Dr., now Sir, Joseph Fayrer, to perform the pioneer work in that part of the globe.

While much has been written upon this subject in

general; very little has been said or done in the special line to which this paper relates.

At Professor Welch's suggestion we conducted a series of experiments in the pathological laboratory of the Johns Hopkins University during the spring of 1893, having for their purpose the determination of the action of rattlesnake venom upon the bactericidal power of the blood.

Dr. Welch's attention was directed to the investigation of this subject by Dr. Weir Mitchell. Drs. Mitchell and Reichert demonstrated that the poisonous properties of rattlesnake venom depend upon the presence of proteid substances. These investigators were the first to demonstrate the existence of the so-called toxic albumins.

In their monograph on the subject, as well as from previous observations, it was apparent that the animals killed by rattlesnake venom decomposed with great rapidity, indeed with such rapidity, that Dr. Formad, who contributed an appendix upon the pathological anatomy of animals dead of rattlesnake venom, believed that there was evidence of the spontaneous generation of bacteria.

Dr. Formad thought it impossible for the bacteria to make their way into the circulation and multiply so quickly. This seemed so improbable to Professor Welch that he suggested to Dr. Weir Mitchell the importance of having this point worked up. Dr. Mitchell kindly gave us a certain amount of poison. We were, however, fortunate enough to obtain a live rattlesnake of the diamond species, known as the *Crotalus Adamanteus*, from which fresh venom was obtained and used in preference to the dried poison supplied us.

It will not be out of place to recall briefly that the order *Ophidia*, of the sub-class *Reptilia*, is divided into three sub-divisions: (1) the *Ophidii Colubriiformes*, or innocuous snakes; (2) the *Ophidii Colubriiformes Venenosi* or poisonous colubrine snakes; (3) the *Ophidii Viperiformes*, or viperine snakes, poisonous.

To the last sub-division, viperine snakes, belong the *Crotalidæ*, or rattlesnakes, called by Fayrer "pit-viper," being distinguished from the *Viperidæ* or vipers proper, by possessing a pit or depression between the eye and the nostrils in the loreal region; a triangular broad head and thick body of variable length.

The *crotalus* is distributed widely over the globe, and all are terrestrial except in India, where quite a number of genera are arboreal; these, however, lack all semblance to the horny scales or rings at the tip of the tail, known as the "rattle," except in the species called *Halys*, where the tail terminates in merely a rudimentary horny spine.

It is of interest to note that the Indian *crotalidæ* are not so venomous as their American congeners, though Asia has a very deadly species known as the *Calloselasma Rhodostoma*, resident in Java and Siam; while South America is represented by the well-known *Jararacca* or *Craspedocephalus Braziliensis*. Australia and Africa likewise contain ophidians of this class but they are little known.

The *crotalidæ* of the United States are represented by ten species and three sub-species, all being equally poisonous, so far as we now know. Of these the *Adamanteus* has three sub-species, one of them, the *Adamanteus* proper, found in this country, extending from North Carolina to Florida; a second, the *Atrox*, resident in the Indian Territory and Texas, also throughout that stretch of country extending to Sonora and

¹ From the proceedings of the Washington meeting of military surgeons.

² Boston Medical and Surgical Journal, April 4, 1889.

southern and lower California; and a third called *Scutalatus*, known only to Arizona.

We had in view in the first place to test the question as to whether the blood of animals killed by rattlesnake-poison had lost any of its germicidal power.

We used Dr. Weir Mitchell's noose for securing the snake and with a sterilized saucer thrust into the mouth of the animal, we collected the venom. In this way we had no difficulty in getting from 0.5 to 1 c. c. of nearly clear, slightly straw-colored fluid, quite sufficient for our purposes. This was diluted with an equal quantity of sterilized physiological salt solution, and 0.25 to 0.5 c. c. of this mixture was inoculated subcutaneously under antiseptic precautions, the dose varying according to the time we wished the animal to live. This was usually from one-half to one hour and a half, but in one or two cases, three hours after the injection.

The injections were in all cases given subcutaneously, sometimes beneath the skin of the abdomen and at other times in the groin. The lesions differed somewhat according to the site of injection. When made beneath the skin of the abdomen, there were most extensive peritoneal hæmorrhages, whereas, when the injections were made in the thigh, these lesions were less extensive, although not absent; here the most striking effect noted beside the deeply discolored integument surrounding the point of injection, were the underlying hæmorrhages into the muscles.

The important lesions were these: most extensive hæmorrhage, with disintegration of tissue and actual necrosis of tissue, for a wide distance around the point of inoculation, with ecchymosis in other parts of the body, particularly in the serous membranes. Another point which served our purpose admirably, was that the blood does not coagulate after death or coagulates only feebly and after a long interval. We therefore had no difficulty in collecting a sufficient amount of the fluid blood, and we did so by withdrawing the blood in less than a minute after the animal breathed its last. We exposed the heart at once, and with sterilized instruments made an incision in the right auricle, and with a sterilized pipette we aspirated from the right heart; and then passing the pipette down into the abdominal vena-cava, we secured sometimes as much as seven or eight cubic centimetres of blood. This blood was collected in a sterilized test-tube and put in the refrigerator. After twenty-four hours, the red blood corpuscles had settled; sometimes a small, soft, dark coagulum had formed, and there was a layer of clear serum.

The usual statement is that the blood does not coagulate. It looks as if it did not coagulate, and as though there was merely a sedimentation. But there is in fact an extremely thin clot, which does not retract from the sides of the test-tube. It is an extremely viscid, sticky coagulum, which adheres to the platinum needle inserted into it. We pipetted off after twenty-four hours, the clear serum, usually collecting 0.5 to 1.5 c. c. The organisms which were used to test the germicidal power of the serum, were the bacillus coli communis and the bacillus anthracis. Professor Welch selected the bacillus coli communis because that is an organism which is normally present in the intestine and also one with which he had experimented upon with normal serum. He took the bacillus anthracis because that is a classic organism in regard to the action of serum. The results were uniform and striking. As a rule, we made a control experiment with normal serum; thus we killed a healthy rabbit and withdrew the serum in

the same way, collected the same quantity, and inoculated at the same time a parallel control, tubes with the bacteria to be tested. The cultures were twenty-four to forty-eight hour cultures. Our bacillus anthracis was obtained in suspension from the spleen of an animal recently dead of anthrax. We wished to obtain the anthrax bacillus free from spores, and thought it better to take it fresh from the animal. Similar results were obtained also with twenty-four-hour anthrax cultures grown at room temperature. We made a suspension in salt solution of the organisms, and inoculated a known quantity, one to two platinum loops of the suspension, into the serum tube. Then we made roll cultures.

The following tables, drawn up by Professor Welch, represent only a certain number of our experiments, and are much abbreviated for the sake of clearness.

BACILLUS ANTHRACIS.
Normal Serum.

No.	No. bacilli inoculated.	After 24 hours.	After one week.
1 A	485	0	0
1 B	8,512	0	0
1 C	210	0	0
2 A	5,292	0	0
2 B	1,628	0	0

Venom Serum.

No.	No. bacilli inoculated.	After 19 hours.	After 24 hours.
1 A	8,512	Countless.
1 B	25	3,233
2	68	250,000
3	3,292	Countless.
4	3,292	Countless.
5	3,292	Countless.

BACILLUS COLI COMMUNIS.
Normal Serum.

No.	No. bacilli inoculated.	Immediately.	After 24 hours.	After 48 hours.	After one week.
1 A	250,000	256	157	Countless.	Countless.
1 B	175,000	188	50	Countless.	Countless.
2 A	29,161	53	0	0	0
2 B	3,150	18	0	0	0
3	9,990	13	38	625	Countless.
4	84,947	238	0	0	0

Venom Serum.

No.	No. bacilli inoculated.	Immediately.	After 22 hours.
1	800,000	1,077	Countless.
2	3,150	6	26,000
3	16,560	32	Countless.
4	9,990	35	Countless.
5	84,947	284	Countless.
6	84,947	231	Countless.
7	84,947	182	Countless.

With the bacillus coli communis, it will be observed that in the case of normal serum, we inoculated 250,000 bacteria. Immediately afterwards, there were 256 colonies; after twenty-four hours only 157 colonies. In other words, there was not only no development, but an actual diminution in the number of bacteria. If the organisms are not all killed at the end of twenty-four hours, the germicidal power ceases, and those which remain multiply. After forty-eight hours, the colonies were countless. In the second experiment, we inoculated 175,000 bacteria, which represented 188 colonies immediately. After twenty-four hours, there were only 30 colonies, and in forty-eight hours they were countless. Taking a smaller number of bacteria, 29,161, there were immediately 53 colonies; after twenty-four hours none: after forty-eight hours none; after one week none. In other words, in twenty-four hours the normal serum had destroyed 29,000 bacteria.

These experiments were uniform in results, and point to one conclusion, that the blood of rabbits killed in one-half to three hours after subcutaneous inoculation with rattlesnake venom, has lost its germicidal power. This is of considerable interest, for it is an indication of a very profound alteration in the blood. This germicidal power of the blood is one of very great significance, on which many of the modern theories of immunity depend.

It is of special interest to ascertain under what conditions the germicidal properties of the normal blood serum are at their highest, and in what way these properties affect the composition of the blood.

The principal workers in this field have been Von Fodor, Nuttall, Wassermann, Kitasato, Buchner, Ogata, Hankin and others. Von Fodor's work had reference to the composition of the blood, and was intended to show that arterial has a more destructive action on bacteria than venous blood, and also that fresh blood has a more destructive action than that which has been standing for some time. It was also found that the germicidal power of the blood was weakened in an atmosphere of oxygen or carbonic acid gas, but the removal of gasses from the blood had no appreciable effect.

A series of experiments showing the effect of moving and stationary blood upon bacteria by means of small globes containing blood, some of which were kept in constant motion and others quite stationary, resulted in no appreciable difference being observed.

Temperature affected very materially the bactericidal power of the blood, which increased with the rise of temperature from 88° to 40° C., and then gradually diminished with the fall.

Von Fodor is of the opinion that the individual predisposition of an animal to an infectious disease stands in close relationship with the germicidal power of the blood. A second series related to the influence of drugs on the power of blood to destroy germs.

Hydrochloric acid had no effect; tartaric acid and quinine, respectively, produced a marked decrease. A slight increase was produced by common salt and carbonate of ammonium, but a more marked effect by the phosphate of sodium, while the carbonate of potassium and sodium showed a very remarkable increase. From these experiments the deduction was made that the bactericidal power of the organism was raised by any drug which increased the alkalinity of the blood. The third series verified the conclusions regarding the alkalization of the blood. Of eight rabbits inoculated with

anthrax all died, whilst of nineteen which had been previously injected with solution of soda only three died. A majority of the sixteen remaining were perfectly free from disease, only a few being fatally affected.

Up to this time, however, the doctrine of phagocytosis as advanced by Metchnikoff held sway, when Nuttall struck the first severe blow to this theory. He, in his most excellent inaugural dissertation at Göttingen in 1890, showed that the destruction of virulent bacteria in the blood of animals by the leucocytes, was not at all essential, but that the serum of blood free from all cellular elements, possessed this power to a degree equal to the blood in its entirety.

Nuttall's work is graphically shown in some twenty-eight tables in his "Beiträge zur Kenntniss der Immunität." He here proves very conclusively, that in the blood bacteria presented marked evidences of degeneration before being taken up by the wandering cells, or leucocytes. It was also seen that the bactericidal power of the blood of different animals varied, and that while in some certain bacteria were promptly killed, in others these were simply restrained for a time or not affected.

Buchner, Lubarsch, Nissen, Stern and Prudden have practically verified these observations. Buchner, particularly, in his experiments upon dogs and rabbits, verified the findings of Nuttall, but went even further and proved that the bactericidal power of the blood of these animals did not *at all depend* upon the cellular elements, but resided in the clear serum which separated from the clot, after the blood had stood a while in a cool place. He also demonstrated that the germicidal action of blood and serum were destroyed by exposure for an hour to 55° C. or by heating to 52° C. for six hours, or to 45.6° C. for twenty hours.

Alternate freezing and thawing did not destroy the bactericidal power of the serum, but it was diminished or completely checked by dialysis with distilled water, or by extreme dilution with the same. He preserved the anti-bacterial action of the serum by making an equal dilution with a six-tenths to seven-tenths per cent. of sodium chloride solution, and was led to believe that the activity of the serum was greater alone, than when the cellular elements of the blood were present, hence he concluded that the active element is a living albumin, having as an essential constituent an alkaline base. This albuminoid substance is thought by Hankin to be identical with his "globulin" isolated from the spleen and lymphatic glands.

According to the views of these experimenters, the germicidal power of the blood resides in the serum alone, and phagocytosis is but a secondary process, the leucocytes taking up the bacteria only after they have been rendered inert by the germicidal power of the serum of the blood and certain other fluids of the body. For our purpose, however, it is not necessary to insist upon the humoral as opposed to the phagocytic doctrine of immunity. All that concerns us is the recognition of the bactericidal power of the blood serum under certain conditions.

The loss of this normal germicidal power helps us to explain the varying rapidity with which post-mortem decomposition sets in. It is well known that persons dead of different diseases decompose with varying degrees of rapidity. We cannot explain this differing rapidity of decomposition simply by variations in temperature, for under the same external conditions

one body will be decomposed in comparatively few hours and another may remain undecomposed for several days. We selected the animals killed with rattlesnake venom because it is well known that they decompose with great rapidity. The bodies of human beings killed by snake venom are also said to decompose with great rapidity.

The results of our experiments furnish a satisfactory explanation of this phenomenon. The blood at the time of death and even before death, has lost all, or nearly all, power of resisting the invasion and multiplication of certain bacteria, so that the bacteria of putrefaction which are normally present in the intestine, develop with astonishing rapidity and even before the animal is cold, produce this wonderful rapid decomposition. Our experiments are also suggestive as regards certain secondary and mixed infections. The toxic proteids of snake venom belongs to the same class of poisons as those formed by toxic bacteria, such as the bacillus of tetanus, of diphtheria, etc.

It is easy to suppose that these infectious diseases may cause a diminution of the germicidal power of the blood against secondary invaders, of which common examples are the pyogenic bacteria present often in our mouths and intestinal canals, and which in an individual whose resistance is lowered by a loss of the germicidal power of the blood, may grow and multiply. In other words, we can understand better the causation of many of these secondary infections.

VARIOLA.

BY S. G. WEBBER, M.D.

(Concluded from No. 19, p. 459.)

CASE XII. Charles B. had had his fingers amputated on account of an injury, and the wound was still suppurating when he was received into the hospital. The eruption was quite thick on his face, arms and legs. While pustular on the face, it was flat and bright red on the arms and legs, surrounded by an

areola. It then became confluent on the face, nearly so on the arms and legs, and became purple. The purple color increased in intensity for two or three days; he trembled much and had chills, with a rather bad-looking tongue. He was indifferent to what passed around him, but seemed to be sensible and conscious.

The curve shows that the temperature first fell from

¹ The cases on which these observations are founded were under my care in the winter of 1869-70 at the Boston Small-pox Hospital. They formed the basis of a paper which was read before the Medical Observation Society, but has never been published. Much of that paper is here reproduced.

the sixth to the eighth day; then the secondary fever began, and the temperature rose to 105.4° on the thirteenth and fourteenth days, then fell and rose again during the desquamation, later rising when abscesses developed, which kept him in the hospital till the early part of May.

The next case was complicated with pneumonia.

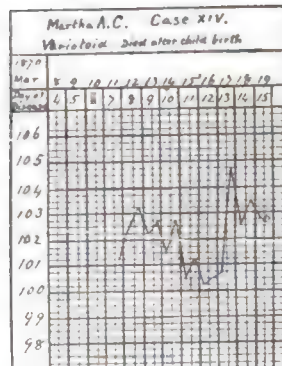

CASE XIII. John C., age twenty-seven, said he had been vaccinated. The scars were not found. The eruption was semi-confluent. He did well, and after

sixteen days his face was nearly clear. He then had a succession of abscesses; between March 22d and April 17th twenty-three or more were opened, and several opened spontaneously.

March 26th. The sputa was rusty-colored and very tenacious. There were sibilant râles over both backs, but no mucous nor crepitant râles could be heard. At the base of the right back the respiratory sounds were diminished, and there was a diminution of resonance. By April 6th these symptoms had disappeared, and he recovered.

The next case was fatal on account of the complication of pregnancy.

CASE XIV. Martha A. C., age thirty-one, said she had been vaccinated ten to fifteen years previously. She noticed the eruption first on her abdomen; the next day she was well covered. The eruption was not well developed, and was accompanied with considerable erythema. She said she had had her catamenia two weeks before. She seemed to be doing well, though the temperature was rather high on the eighth and ninth days for varioloid, yet it was falling, not rising.

The attendant thought she was pregnant when she came in, but she denied it. On the twelfth day labor pains appeared, and then she said she was about

seven months advanced. No advance was made until the fifteenth day. She vomited a dark liquid during the night, and passed blood at stool. The labor caused the temperature to rise.

Her child was born in the forenoon, entirely free from any eruption. The uterus contracted well. The pulse was very feeble, and in the afternoon she died.

CASE XV. B. M. This was a case of varioloid. The curve of temperature is given to illustrate the distinction between the rise caused by bronchitis and the secondary fever of variola.

The next two cases were interesting in that the patients had all the symptoms of variola without the eruption.

CASE XVI. The attendant at the hospital had the care of the first case October 26, 1869. November 6th, just eleven days after, he was attacked with severe pains in the loins and fever; chills very slight, if any, tongue dry, pulse 90. The next morning he was feverish; pulse 96, eyes congested, temperature 102.6°, evening 102.6°. The third day he was better; pulse 84, temperature 101.6°. The fourth day he was nearly well.

CASE XVII. Beginning on the evening of November 7th, and lasting until November 9th, I had an attack of headache, chilliness and feverishness, which obliged me to lie down whenever I had the opportunity. The pulse and temperature were not taken.

In both these cases there was probably the variolous poison acting, but not strong enough to produce the fully-developed disease.

In both these cases there is seen, probably, the effect of the variolous poison in systems nearly protected, and these may be compared to the sore throats noticed during epidemics of scarlet fever.

The treatment in all the cases was chiefly supporting. Stimulants were given freely when it seemed necessary. In each case, that amount was prescribed which at the visit seemed sufficient to have marked effect; but a general order was to give more in case there seemed to be call for it. The sudden fall of temperature after the ingestion of large amounts of rum in several cases would favor the view that it was beneficial. It was also ordered that when the patient's breath had the odor of alcohol the dose should be diminished or omitted. Milk was given freely, a mug being left by the bedside for the patient to drink as he desired. In most cases the patients preferred the milk to water for a drink. The amount of milk thus drank was occasionally very great. One patient drank at the crisis about seven quarts in twenty-four hours; another took nearly five quarts in twelve hours. The most reasonable explanation of this great consumption of milk may be found in the great drain on the system caused by the filling out of the large number of pustules and the consequent exhaustion, which called for the means of repair. Solid food was given only after the tongue had become clean, though eggs, raw or soft-boiled, were allowed before this.

The only local application to the face was the following:

R Acid. Carb. gr. v
Glycerine
Aque ss 3i

This was applied freely several times a day, so as to keep the pustules and crusts moist. The application was used as soon as the eruption became pustular, or sooner. Whenever this was faithfully used it had the

best effect in preventing itching, smarting and burning. In only two or three cases was there any inclination to scratch or rub the face, and only once, when the wash had not been used often enough, was there any complaint of discomfort. In nearly all cases, when asked, the patients said there was no uncomfortable sensation.

The normal course of the temperature has already been noticed in both variola and in varioloid. In eight cases there was well-marked increase of temperature during the period of desquamation. In six cases there was an increase at that time, but there were also abscesses or inflammation which rendered the cause of the increase obscure and gave it a different character. Dr. Leo first attracted attention to this fever of the desquamation stage. Sometimes there is only one day of low temperature between the secondary fever and this, but there is a marked rise as compared with that interval, however short it may be and the few days next succeeding.

There is a difference observable in the rise of the temperature according to the character of the inflammation causing it. In abscesses the variation between evening exacerbation and morning remission is quite great; but in inflammation affecting the lungs the temperature is maintained more steadily at a high figure.

The thermometer then is of value not only as aiding in the diagnosis between variola and varioloid, which could be made from other symptoms; but is also a guide to judging of the condition of the patient, showing early that there is a new morbid process setting in. Sometimes it is the first notice given of the occurrence of suppuration ending in abscess, and if the patient is inclined to conceal such an accident, the rise in temperature would lead to an examination which would reveal the cause. Also the character of the rise would show whether there was a probability that the lung was becoming affected or whether there was merely an abscess forming.

The thermometer is also valuable as a means in forming a prognosis and is invaluable as a means of setting the physician's mind at rest in regard to the welfare of the patient. If the attendant can be trusted the physician may leave his patient longer unvisited with safety, for the thermometer will surely show if there is reason for sending for him. So long as the temperature is low there is safety and no complication is likely to arise except hæmorrhage, which gives unmistakable notice of its presence.

There were received into the hospital 34 patients with variola and varioloid, two with measles and two with other eruptions. Of the 34 patients 21 had variola, 11 had varioloid and in two cases there might be doubt, one entering after desquamation had advanced considerably, which was probably a case of variola.

These cases may be tabulated thus:

Variety.	No. of Cases.	Deaths.	Mortality.
Confluent	7	2	28.5%
Semi-confluent	2	0	..
Hæmorrhagic	4	3	75
Corymbosæ	1	0	..
Discrete	6	1*	16.6
Doubtful	2	1†	50
Varioloid ‡	11	0	..
Total	33	7	21.21

* From pyæmia. † From pregnancy. ‡ Cases xv and xvi are not included in this table.

In five cases the duration of the period of incubation was well marked. In one it was ten days, in one it

was eleven days, in two it was twelve days, in one it was probably eleven or twelve days.

In eleven cases the eruption was seen two days after the first feeling of discomfort; in twelve, three days after; in eight, four days after; in one, in less than two days; in two cases the date was not fixed, and in one case there was no eruption.

Of those cases whose duration could be accurately determined varioloid lasted from 13 to 29 days, there being one case continuing each of the following periods 13, 16, 17, 19, 20, 21, 23 and 31 days, and two cases 15 days. The cases of variola which recovered lasted one each during 31, 32, 41, 45, 56 and 60 days two cases each 27, 40 and 42 days. The fatal cases died, one in less than five days, one in 8, 9, 14 and 16 days, and two in 15 days.

Except in the hæmorrhagic variety, which is much more quickly fatal, the date of greatest mortality and danger is between the fourteenth and sixteenth days.

Chills which are mentioned as a prominent symptom at the commencement were absent in many cases, and in most of the others were so slight as not to be mentioned by the patient unless questioned in regard to that point. Later in the disease during the suppuration and still more during desiccation there were frequently severe chills.

In only one case which recovered, was there entire absence of salivation; usually this symptom was well marked.

In three cases there was pulmonary complication; in only one showing decided signs of pneumonia; the other two being probably only bronchitis and pleurisy.

Vomiting at the beginning of the disease occurred in both severe and mild cases, being, however, rather more protracted in severe cases. It did not seem to have much value for prognosis.

In two cases there was a pustule on the conjunctiva and in one case during the occurrence of abscesses in other parts there was a collection of pus under the conjunctiva.

In four cases variola occurred after reported vaccination. In one of these the patient said the vaccination did not take well, in another the scars could not be distinguished with certainty, in two cases the examination was not accurate enough to state positively what was the condition of the scars. The other cases of variola had never been vaccinated. A winter's experience in a small-pox hospital during an epidemic would probably cure one of any prejudice against vaccination. In only two cases of variola was it probable that vaccination may have been well performed, and both of these were mild cases and recovered. Comparing the severity and duration of the disease in the 15 who had been vaccinated and the 19 who had not, or had been only imperfectly protected, there can be no hesitation in regard to a decision in favor of vaccination.

A few reflections occur, as I now look over this paper, in regard to the improved sanitary condition and care of the City as compared with 1870. Then, a patient with the scabs still on his face could ride in a public car without giving rise to any inquiry, scarcely to comment. A patient now would not be sent to the hospital alone, nor would such an one wander about the streets trying to find it, as in case VI. And it would not now be possible for so many to take care of their friends until they died with the disease, if doctors did their duty.

THE TREATMENT OF PULMONARY TUBERCULOSIS BY THE SUBCUTANEOUS USE OF THE CHLORIDE OF GOLD AND SODIUM WITH THE IODIDE OF MANGANESE.

BY WM. S. BOARDMAN, M.D., BOSTON.

WE have read and heard so much about new remedies and modifications of new remedies for the treatment of phthisis, that now to many the subject fails to excite an interest.

The methods of treatment are too numerous to mention. One is almost startled by the list of drugs and methods proposed, in reading Solis-Cohen's article on "Tuberculosis," in "Hare's System of Practical Therapeutics." Yet there must be something beneficial in these remedies, even if there is nothing specific.

The brilliant methods of Koch, dimmed by the noxious elements in his tuberculin and brought to a glow again by the researches of Klebs and Hunter, are undoubtedly more for good than anything hitherto proposed. Although we seem so near the desired result, it has not yet been obtained in the ideal that was first conceived; nevertheless, it behooves us to make the most of what we have, while striving for something better.

From the earliest time, the attempt has always been made to combat the marasmus of phthisis by dietetic and hygienic measures. How slow and uncertain a procedure it has been is only too well known to us all. If in any way we can aid the process of nutrition and maintain or increase the strength of the patient, a great deal will be done towards staying the disease, if not directly tending to a cure.

One mode of treatment that has been tried considerably yet spoken of by comparatively few writers, is the subcutaneous use of a solution in glycerine, of the chloride of gold and sodium with the iodide of manganese. In March, 1891, an article in the *Medical Record*, by Dr. J. B. White, extolled this combination as a treatment for phthisis, and cited a number of cases to show the beneficial results obtained. Another article in September, 1892, by the same author, appeared to supplement and confirm the results of the first paper, being written in a very earnest and pleasing manner. As the combination of the chloride of gold and sodium with the iodide of manganese, is, under ordinary circumstances, likely to result in the formation of a precipitate, the author of the above-mentioned articles was asked to state the method of preparing the solution. Since the process was not given and the injection fluid could only be obtained in New York, it was thought to be of sufficiently scientific interest to the profession to have an analysis of Dr. White's preparation; and Mr. Wm. C. Durkee, Ph.G., kindly consented to undertake the chemical work with this result.

"The proximate chemical examination of the injection fluid is as follows. It has a dark-amber color, with a specific gravity of 1.260, a styptic taste and a syrupy consistency.

"According to Dr. J. Blake White's statement, each drop should contain the equivalent of one-fiftieth of a grain of the chloride of gold and sodium, and one-fiftieth of a grain of the iodide of manganese, that is, each drop should represent one-twenty-fifth of a grain of the combined salts.

"He does not mention the method of obtaining the drop, whether from the bottle or a medicine-dropper;

and although changes in the viscosity of the liquid owing to the temperature, the rapidity with which the drops are formed, and the shape of the material from which the drop falls largely govern the size, it was assumed that a drop from the original five-cubic-centimetre bottle, at about 70° F., and forming at a speed of one in two and a half seconds, would be about the size usually obtained and probably intended by the quoted statement.

"Several careful weighings of ten-drop quantities of the liquid were made and the drops found to average 77 milligrammes each, and supposably contained one-fiftieth of a grain (.0013) of U. S. P. strength of chloride of gold and sodium, and the same quantity of iodide of manganese, or 169 mg. of each in 10 gm. of injection.

"Ten grammes of the fluid were found to contain .01737 gm. of metallic gold, equal to .05352 gm. chloride of gold and sodium U. S. P., or about one-third the amount claimed. The liquid is composed mainly of glycerine, and contains free iodide, iodine in the form of iodate (also as iodide), chlorine, sodium, potassium and manganese.

"As the method of preparing the injection fluid recommended by Dr. White was not made public, the following process has been devised, which yields a solution containing the ingredients he has reported as useful and of the strength he recommends. Take of

Gold and sodium chloride, U. S. P.	1.69 gm.
Manganese sulphate	2.44 gm.
Potassium iodide	4.62 gm.
Diluted alcohol	10.0 c. c.
Glycerine	of each a sufficient quantity.
Distilled water	

"Dissolve the gold and sodium chloride and one gramme of potassium iodide separately, in sufficient glycerine to make each solution weigh 25 gm. using only a very gentle heat, if any; when cold mix the two solutions. Dissolve the manganese sulphate in sufficient distilled water to make 10 c. c., and 3.62 gm. of potassium iodide in sufficient diluted alcohol to make 10 c. c.; mix the two solutions, and allow the containing vessel to stand in powdered ice for several hours, to thoroughly precipitate the potassium sulphate. Then decant 10 c. c. of the clear liquid into 40 gm. of glycerine; evaporate on a water bath until the total weight is reduced to 40 gm., and add glycerine to make 50 gm. Mix this solution with the solution of gold and sodium chloride, and keep in amber glass-stoppered bottles. Each 77 mg. (about one drop) contains the equivalent of 1- $\frac{3}{5}$ mg. (one-fiftieth of a grain), of gold and sodium chloride and the same quantity of manganese iodide."

The injections were given in the forearm, upper arm and subclavicular region by an ordinary hypodermic syringe.

The solution prepared has been used in the manner advised by Dr. White, the initial dose usually being one drop (equal to one-twenty-fifth of a grain of the combined salts of gold and manganese) diluted with a few drops of a one-per-cent. solution of carbolic acid, and increased only as the constitutional disturbance remained at a minimum or ceased to appear after several doses.

In some patients the reaction appeared within two hours — as headache, backache and general malaise —

¹ It is best to prepare this chemical or to use an article which is known to be of full strength, as market samples were found to contain less gold than the labels indicated.

lasting twenty-four to forty-eight hours; in others it was but little marked and disappeared within one or two hours after an injection.

The pulse has been found to be full and slow with subnormal temperature in some, while in others the pulse was increased in rate with a slight rise in temperature.

The local effect varied, in some the solution caused considerable inflammation, in others the injection was only marked by an induration and slight tenderness about the puncture. It seemed to depend upon the amount of loose connective-tissue present and the individual susceptibility to irritation.

Cough-mixtures, tonics and hygienic measures have also been made use of as opportunity permitted.

One thing was observed quite generally, as noticed by another writer — within two weeks or thereabouts after beginning the injections, the appetite was increased, so much as to cause the remark of the patient to the effect.

The cough and expectoration in some were lessened, in others not appreciably affected. Night-sweats usually ceased. The general appearance and feelings of the patients improved, and they did not hesitate to declare themselves greatly benefited.

On making a physical examination of a patient after a few injections, the former condition of things may be somewhat aggravated. At such a time I have found the signs more marked, especially the auscultatory signs; later the results were variable.

The theory that the preparation of gold is eutrophic, while the manganese is anti-æmic, seems to be well borne out. That an improvement can be secured in some cases I feel quite confident, but as to complete and permanent recoveries I am not so certain.

The exact way in which these injections affect the pulmonary tissue is more or less a matter of conjecture; nevertheless, the remedy appears to act as a tonic to the waning strength of the patient, also to cause a certain amount of irritation and inflammation around the foci of infection (as sometimes shown by bloody sputum after a large dose), which may eventually result in an encapsuling of the pathological portions, or their replacement by dense fibrous tissue.

However, be it as it may, the subcutaneous use of the chloride of gold and sodium with the iodide of manganese certainly improves the majority of patients subjectively; and if a cure does not result, they are at least in a most promising condition for treatment by modified tuberculin or its allied products. The strongest argument in favor of this treatment is the fact that when properly given no injury can be done, while there is great probability of an improvement if not a cure.

Appended is the full report of ten cases treated by gold and manganese, also the tabulated report of fifty-four cases, — some having been treated with gold and manganese, and some with Hunter's modification B. (kindly furnished by Dr. Trudeau of Saranac Lake, N. Y.).

In regard to the latter method of treatment, I will briefly state, that while not obtaining the results of Dr. Trudeau, I found much in its favor to warrant a further trial.

I have also been using for several months Klebs' Tuberculocidin, and so far with considerable satisfaction.

In connection with this paper, I wish to thank Dr.

E. M. Greene for his valuable services in the examination of sputum, and Dr. F. C. Cobb for laryngeal work, also Mr. Wm. C. Durkee, Ph.G., for most perfect chemical work, and Dr. E. O. Otis for kindly suggestions.

Medical Progress.

REPORT ON MENTAL DISEASES.

BY HENRY R. STEDMAN, M.D., BOSTON.

MENTAL DISTURBANCE IN EXOPHTHALMIC GOITRE AND MYXŒDEMA.

HIRSCHL¹ considers that exophthalmic goitre is not often complicated with a psychosis. Mania is the ordinary intercurrent psychosis in a simple typical case. If another form comes on in the course of exophthalmic goitre, it is usually a complication of a coexisting or complicating neurasthenia, hysteria or alcoholism rather than of exophthalmic goitre itself. The psychical type of a patient with exophthalmic goitre is often between that of a healthy person and that of maniacal exaltation with signs of degeneration. This is very common, but not constant. It has equal value with the three cardinal symptoms, and can aid the diagnosis in doubtful cases. The explanation of complicating mania and this psychic type is not forced if we regard the disease as due to functional or anatomical disturbances in the medulla. These conditions can then be ascribed to vascular paresis of varying degree in the cortex. By thus localizing the disorder in the medulla we can better explain the less frequent pulse and the anxiety in psychical depressed states.

Clouston's² study of the mental symptoms of myxœdema and the effect on them of the thyroid treatment is instinctive in showing that the contrast which marks their physical condition is equally evident in the mental states of these opposite affections of the thyroid. The general course of the mental disease in his cases was, first, slowness of mental action; secondly, emotional depression; next, irritability, morbid suspicion, non-resistiveness to outward causes of disturbance and general loss of control or maniacal outbursts; then, enfeeblement, with some exaltation in some cases; and, lastly, lassitude, hebétude ending in a condition of mental negation just before death. Two pathological facts that have lately come under his observation in regard to the cerebral cortex have impressed him deeply with the possible recuperative capacity of the cortical structure. One was a puerperal case of a few weeks standing—a *curable case by every clinical standard*—who died of maniacal exhaustion, and whose cortical cells were found in a state of marked and advanced degeneration, with spider cells and proliferated nuclei round the vessels and the neuroglia. If such degeneration is really curable, then we need not despair of recovery in many advanced cases of mental disease. The second fact is the actual cure of the prolonged mental enfeeblement of myxœdematous insanity by the thyroid treatment. He is convinced that we need not be hopeless of some day discovering remedies that will cure some of our cases of chronic melancholia, chronic mania and mild dementia, the pathological changes in whose brain cortex

he has often seen to be very similar to those found in one of his myxœdematous cases.

THE ALTERATIONS OF THE PERIPHERAL NERVES IN GENERAL PARESIS.

G. Datto³ reports autopsies of eight cases of paresis in which he carefully examined by several methods (both fresh and after hardening) the peripheral nerves (various cranial nerves and nerves of the brachial and lumbar plexuses). His general results were as follows: The alterations met with were those of parenchymatous neuritis in different degrees. This was constant in all the observations, the variations in the intensity of the pathological process in each, it is suggested, were possibly in relation to the intensity of the clinical symptoms. The cranial nerves were least affected in comparison with the others. The alterations were not systematic in their distribution, sometimes involving the motor, sometimes the sensory nerves; which fact in part explains, the author holds, the varied clinical syndromes of the disease. It also supports the view that we have in paresis a widely disseminated degenerative process affecting the most diverse organs of the nervous system.

Campbell,⁴ also, has made a careful study of the neuro-muscular changes in ten cases of general paralysis. He found the vagi extensively and strikingly diseased, more so almost than any of the peripheral nerves, and decidedly more than any cranial nerve. It is impossible to attach too much importance to the remarkable singling out of the vagi for such extreme degeneration in this disease. The changes in the mixed spinal nerves and their peripheral terminations appeared to be a combination of a parenchymatous degeneration and an interstitial or adventitious inflammation. This investigation confirms those of others in regard to the remarkable fact that the more peripheral the site examined in the mixed trunk the more extensive the degeneration will be found to be, and when the motor and sensory branches are reached it is more advanced and pronounced. The degree of degeneration of the spinal nerve roots was always considerable, but never extensive. The changes in the muscles do not, in the main, differ from those described in connection with other neurites. They are probably chiefly secondary effects of the nerve degeneration. It is extremely difficult to frame a distinct pathology for the neuro-muscular changes attendant on general paralysis, as there is so little knowledge of the precise nature of the pathogenic influence or factor which determines it; still, taking these changes in general paralysis separately into consideration and comparing them with those in other varieties of multiple neuritis, we find that there exists a close resemblance from an anatomical standpoint, and there is further one group with which the changes in general paralysis can be pathogenetically compared, namely, the *primary intrinsic toxic*; the secondary toxic, the purely toxic, the endemic, the rheumatic, and the cachectic or senile, being out of the question. This naturally does not refer to cases of alcoholic or syphilitic origin.

INEBRIATE ASYLUMS IN GERMANY AND SWITZERLAND.

Tilkowski⁵ visited and inspected five of these asylums: In Switzerland, Ellixen in Canton Zurich, Nüch-

⁵ Jahrbüch. für Psych., xii, 1.

bern in Canton Bern, and Pilgerhütte in Canton Basel; in Germany, the Linberg group at Düsseldorf and the colony at Bielefeld. He gives the special rules of them all. The common principles involved are:

(1) All asylums in Switzerland and Germany, as at present constituted, rest on the general principle of voluntary entrance and voluntary exit. Forced detention is excluded. [In one Swiss canton, residents of the canton (St. Gallen) can be committed against their will for a definite time; but here inmates can be expelled for non-payment of dues or violation of the rules.]

(2) Insane, demented and epileptics are excluded from all. In Ellixon a certificate of sanity is required. If an inmate becomes insane, he is sent to an asylum.

(3) Total abstinence is required in all, even by the staff and attendants. Moderate use by drinkers is irritating and leads to a relapse, and small amounts do them harm. The attendants must abstain, for the example, and also because they eat at the same table. An inebriate does better if he sees no liquor, and the normal man can do without it. It is an error to think that sudden withdrawal of drink is dangerous.

(4) The fundamental principle is compulsory labor. Physical out-door work is best, and labor makes the cost of maintenance less.

(5) The food seems very liberal, abundant and strengthening, but not inviting.

(6) No drunkard can have money, visit taverns, or go out without leave of superintendent.

All the German and one Swiss asylum (Pilgerhütte) have a religious superintendence, which may aid in cure. Ellixon and Nüchbern are purely humanitarian. The religious ones take in depraved patients. In Lower Austria medical direction obtains, and forced detention. Hence the inmates need more watching. He concludes that all treatment must conform to medical and psychiatric science. Religious-moral influence is desirable, but chief stress is not to be laid on it. It is bad to mix the drunkard with the depraved. Principles 3 and 6 should be adopted by Austrian asylums also.

THE BOARDING-OUT OF INSANE.

The commissioners in lunacy for Scotland report* that during the year 1892 this class of patients has increased by 84, which means an increase of four per cent. and a corresponding diminution in the proportion maintained in establishments. At the same time the relative cost of the two methods has undergone no alteration. During the past six years the proportion of all pauper lunatics boarded out has oscillated between 23% and 24%, and it would almost seem as if this represented the limit of this method of providing accommodation. With regard to the possibility of the presence of insane individuals exercising a hurtful influence on the sane among whom they are placed, an authoritative statement is given by one of the deputy-commissioners who has had fifteen years' experience of this method.

"On reviewing," he says, "the private-dwelling system as a whole, my opinion is that there is no harmful influence on the guardians from the presence of the insane in their houses; and this is the verdict of a host of guardians to whom I have spoken on the subject. The care of the insane in private dwellings, according to my experience, has more frequently had an elevat-

ing than a harmful effect on the guardians and their surroundings, as it has raised the standard of both personal tidiness and of household order and cleanliness." While as regards the possible hardships attending the removal of patients to out-lying parts he remarks that this is more apparent than real, that the great majority of boarded-out insane are more accessible to relatives than patients in asylums are, and that even in the case of patients belonging to one of the suburbs of Glasgow who are boarded out in Islay, there have been no complaints.

THE IMPORTANCE OF MENSTRUATION IN DETERMINING MENTAL IRRESPONSIBILITY.

Krafft-Ebing⁷ reaches the following conclusions on this subject:

(1) It is useful to consider the mental soundness of women during menstruation from a medico-legal point of view.

(2) It is advisable where a woman is held on a criminal charge to ascertain whether the commission of the act coincided with the menstrual period; and by "period" is meant not only the days when there is actual flowing, but those before and after as well.

(3) It is best to advise examination of the mental condition when such coincidence is established. This is indispensable when there is a personal history of neuropathic defect, of mental disturbance at the time of previous menstrual periods, or when the nature of the act reveals any striking features.

(4) When the menstrual process exerts a powerful influence on the mental life of the subject the accused should be given the benefit of extenuating circumstances in the infliction of the penalty, even although there be no proof of menstrual insanity.

(5) When the offence or crime has, in a person whose mind is impaired, occurred during the menstrual period she must be declared irresponsible, for there is every reason to think the act due to emotional impulse.

(6) But individuals who by reason of menstrual insanity would benefit by acquittal on this ground should be considered as dangerous in the extreme and subjected during the times of the menses to close surveillance. It is best to confine them to an asylum for the insane where they will be comfortably cared for and often cured of this menstrual instability of mind.

DELUSIONS OF PERSECUTION.

Neisser⁸ reports the case of a man aged forty-three years who had delusions of persecution; he had been poisoned, attempts had been made to kill him, etc. He had been suffering from these delusions for many months, otherwise he was perfectly normal, conversed naturally and occupied his time with work. The case teaches that the claim of many authors that paranoia is characterized by fixed delusions of persecution is not broad enough to serve as a definition for the disease. Paranoia consists essentially in the tendency to evolve delusions of persecution. If a paranoiac could suddenly be robbed of all his delusions, he would still be insane, and in a short time he would have a new set of delusions. In the reported case this was entirely wanting. The existing delusions were probably the sequelæ of some acute disease with delirium, possibly some organic disease of the brain, the result of syphilis.

Reports of Societies.

THE NEW YORK NEUROLOGICAL SOCIETY.

STATED Meeting, held at the New York Academy of Medicine, Tuesday evening, April 3, 1894, DR. M. ALLEN STARR, President, in the chair.

A CASE OF AMYOTROPHIC LATERAL SCLEROSIS,

presented by DR. CHARLES HENRY BROWN.

The patient was a boy aged fifteen who two and one-half years ago began to notice first a loss of proper speech, difficulty in whistling and in moving the tongue. These symptoms were rapidly followed by difficulty in deglutition, closing of the eyes, deafness and inability to move the facial muscles. After a few weeks he was unable to use the fingers freely in buttoning and unbuttoning his clothing. At present the patient is extremely emaciated. There is paralysis of the seventh nerve on both sides, and the "taper" mouth. There is trophic degeneration in the muscles of the face and neck. The tongue is very much atrophied. The larynx is distorted. He presents all the symptoms of nuclear implication of the bulb and there is glosso-labio-laryngeal paralysis. There is atrophy of numerous muscles in the upper extremity and of a few in the lower extremity. There are general fine and coarse fibrillary twitchings all over the body; exaggeration of superficial and deep reflexes and slight tonic and spastic action in the movement of many muscles.

A CASE OF PROGRESSIVE MUSCULAR DYSTROPHY,

presented by DR. ALFRED WIENER.

The patient was a male, aged twenty years. He was in good health up to May, 1893, when he began to suffer considerable pain in the region of the liver and spleen. This was most severe on walking. Soon afterwards he began to experience difficulty in going upstairs, and he noticed that he was growing very much thinner. His weakness was at first confined to the muscles around the thigh; from here it spread up along the back and involved the muscles of the neck and shoulders. There was no vesical or rectal trouble. There is no history of alcoholism or syphilis. Family history negative.

The patient's present condition is as follows. No mental symptoms. Voice and speech appear to be normal. He is very much emaciated, especially in the neighborhood of the shoulders, back and thighs. He assumes the position of one with a marked lordosis, and walks with a waddling gait. On lying down it is impossible for him to turn over or lift his head from the pillow. His muscles are soft and flabby to the touch. There are no contractures nor fibrillary twitchings; no vaso-motor or trophic disturbance. The thoracic and abdominal organs appear to be in perfect condition. There is present no pseudo-hypertrophy in any of the lower muscles, nor does the patient give a history of any having existed. The deep reflexes are all much diminished. The nerves are not painful to pressure and there is no special tenderness. The lordosis is due to the paresis of the muscles of the dorsal and lumbar portions of the back.

DR. JOSEPH COLLINS said that the case presented by Dr. Brown was very similar to one under his observation at the present time, excepting that his patient was a man thirty-four years old, in whom the symptoms came on rapidly about six months ago. It is

very uncommon to see the disease at such an early age as that of Dr. Brown's patient, but he thought that cases showing the occurrence of the disease at even a more tender age have been recorded. The involvement of the fifth nerve that Dr. Brown's patient seemed to present he had never before heard of. The patient presented by Dr. Wiener seemed to be a typical case of muscular dystrophy, and one whose pathognomonic symptoms were in marked contrast to the case of amyotrophic lateral sclerosis shown by Dr. Brown.

The PRESIDENT said that the contrast between the cases shown by Drs. Brown and Wiener was interesting; one presented the typical features of amyotrophic lateral sclerosis, namely, atrophy, fibrillary twitchings, increased reflexes and bulbar invasion; the other showed a pure dystrophy, without twitching and without marked change of reflexes.

DR. E. D. FISHER said the cases presented by Drs. Brown and Wiener represent two distinct classes of diseases. The first shows apparently a rare condition in which an inflammation has affected the bulbs and later the anterior horns in the cervical region, with involvement of the lateral columns. In other words, we have amyotrophic lateral sclerosis with bulbar symptoms. The usual and not uncommon order of sequence is that of involvement of the cord, with extension later to the medulla. Dr. Fisher said a patient recently under his observation, aged twenty, presented bulbar symptoms of rather acute onset; death resulted suddenly, probably from some involvement of the respiratory centre in the medulla. The autopsy revealed softening in the region of the glossopharyngeal and pneumogastric nuclei. That case would probably have presented a similar clinical history, if the patient had lived.

DR. B. SACHS said he agreed with the diagnosis of amyotrophic lateral sclerosis in Dr. Brown's case. Dr. Wiener's case was undoubtedly one of progressive muscular dystrophy.

DR. WILLIAM M. LESZYNSKY called attention to the fact that in Dr. Wiener's case the upper part of the trapezius muscle was atrophied, while the lower part escaped. This partial atrophy, he said, usually occurs in progressive muscular atrophy of spinal origin.

DR. SACHS said that the partial atrophy of muscles may also occur in spinal dystrophies.

The PRESIDENT said that in three cases of amyotrophic lateral sclerosis coming under his observation, the bulbar symptoms were very prominent.

DR. SACHS expressed the opinion that the bulbar symptoms in amyotrophic lateral sclerosis were due to a natural extension of the disease upwards. He inquired whether there was any involvement of the eye in these cases.

DR. BROWN said there might be ophthalmoplegia.

DR. L. C. GRAY said he had seen the eye involved in one case.

DR. BROWN, in closing the discussion, said he presented his case as a typical one of amyotrophic lateral sclerosis, but rare in the fact that it had commenced in the bulb and extended downwards. He thought this type of nuclear trophic and motor disorder was somewhat acute in its manifestations, and rapidly ran its course. He considered that his case was in *status quo*, and would progress no further so far as degeneration of muscles was concerned. The boy presented a

typical picture of a glosso-labio-laryngeal paralysis, which is an extremely rare condition in childhood. The fibrillary twitchings and slight spastic actions and increase of the reflexes undoubtedly contribute to the picture of a lateral sclerosis.

The PRESIDENT exhibited a diagram showing the areas of anesthesia in the arms as the result of lesions involving different segments of the cervical and dorsal portions of the cord. This diagram, he said, was the result of a careful study of a large number of cases—either coming under his own observation, or reported by others—in which the spinal cord was involved. The result seems to show that for each segment of the cord there is an area of the skin which becomes anæsthetic when that segment is involved.

A CRITICAL REVIEW OF THE VARIOUS THEORIES OF URÆMIA, BASED UPON ORIGINAL EXPERIMENTAL OBSERVATIONS.

DR. C. A. HERTER read a paper on this subject. He began by stating that few subjects of a medical nature have received more attention at the hand of clinicians and investigators than that of uræmia. Yet at the present time there is an uncertainty as to the nature of the uræmic state that is discouraging both to the student of pathology and the practitioner who seeks to understand the conditions, he is called upon to treat.

He first gave a brief historical sketch of the growth of opinion regarding the nature of uræmia, and then reviewed in detail the various theories that have been advanced. The first one taken up was that known as the mechanical theory of uræmia, which has its chief basis in the clinical and post-mortem studies of Traube, who was impressed with the facts that in many cases of Bright's the blood is impoverished in its corpuscular and proteid elements, the left ventricle is hypertrophied, and the arterial tension is greatly increased. The hydræmia combined with high arterial tension was supposed to account for the cerebral oedema found at autopsy. The uræmic symptoms, Traube referred not to cerebral oedema, but to the anæmia of the brain, resulting from the pressure exerted by this oedema. There are objections to this theory. In the first place, oedema of the brain is present in only a small proportion of cases where there have been unequivocal symptoms of uræmia during life. There have been many cases of kidney disease with no hydræmia, no cardiac hypertrophy and no increase of arterial tension; yet even when these latter conditions are present, there is usually no oedema of the brain. In the second place, oedema of the brain is found in conditions where Bright's is absent, and there are no symptoms of uræmia. Then again, drugs which produce convulsions may produce cerebral oedema, and it is likely that the oedema of the brain seen in uræmics is often the consequence rather than the cause of the convulsions. A further objection to the mechanical theory is that lowering of the arterial tension, where it is high, does not necessarily relieve the uræmic symptoms. The dyspnoea of Bright's is often thus relieved, but usually not the convulsions. Bleeding frequently stops the latter, but it checks them often also where there is no excess of tension. The effects of bleeding cannot be used as an argument in favor of Traube's theory, because it may be claimed that the bleeding relieves the circulation of poisonous substances.

The carbonate of ammonium theory. This was ad-

vanced by Frerichs, and is based upon the following propositions:

(1) It is a well-known property of urea to be readily transformed under favorable circumstances into ammonium carbonate.

(2) Carbonate of ammonium can always be detected by chemical means in the blood of uræmic patients.

(3) The injection of ammonium carbonate into the blood of animals gives rise to the symptomatic group of uræmia.

The fate of Frerich's theory hangs on his second proposition, namely, that the blood of uræmics always contains ammonium carbonate. From numerous experiments made by Gobeë, Oppler, Zalewsky and others, including the author, the following conclusions may be drawn: (1) That no ammonium carbonate or only a small amount is found in the blood of uræmic persons. (2) That amounts of ammonium carbonate far smaller than the quantity required to kill are readily detected. (3) That urea injected into the blood of dogs is not converted into ammonium carbonate. We may therefore state that Frerich's second proposition is without substantial foundation. It has been stated that the ammoniacal breath occasionally met with in uræmic patients is evidence of ammonia in the blood. It is more likely to be found in uræmics with gastro-intestinal symptoms, and the ammonia probably comes not from the blood, but from the gastro-intestinal tract.

The theory of Trietz differs from that of Frerich's mainly in that it supposes the conversion of urea into ammonium carbonate to take place in the intestine instead of the blood. He holds that it is by the entrance of the ammonium carbonate into the blood that the uræmic state arises, and the objections already made to the proposition of Frerichs, that uræmic blood contains ammonium carbonate, apply here with equal force.

The potassium theory of Felz and Ritter is based upon the idea that the potassium of the blood-serum, which is normally present in very small amount, might accumulate under pathological conditions and cause death, the potassium salt being rapidly fatal in animals when injected into the veins in even inconsiderable quantity. The experimental and chemical evidence of various observers is strongly opposed to this theory and it may be unhesitatingly abandoned.

The theory of Brown-Séquard. According to this writer, the kidney elaborates an internal secretion which is essential to health, and the suppression of which is responsible in a large degree for the phenomena of uræmia, while the accumulation of toxic substances in the blood is thought to have little or no influence in causing uræmic symptoms. The following are the chief facts upon which this hypothesis rests. (1) It is claimed that the injection of kidney extract into the circulation of a nephrectomized dog, causes the temporary disappearance of uræmic symptoms. (2) It is held that the well-authenticated cases of survival of patients with anuria for a week or more without any signs of uræmia, especially in cases of mechanical obstruction of the ureters, is evidence that it is owing to the internal secretion of the kidney that this inhibition of uræmic symptoms takes place. All the facts advanced in support of the first proposition, Dr. Herter said, are equivocal, and those advanced to support the internal secretion theory are equally weak.

The theory of extractives and toxines. The extractive theory of uræmia refers toxæmic symptoms to the accumulation in the blood of the extractives usually

found in urine; among these may be mentioned xanthine, uric acid, creatinine, etc. In order to show that a substance plays a part in the production of uræmic symptoms it is necessary to prove that this substance is present in the blood in uræmia, or is present in excessive amount, and that the substance is toxic in the higher mammals. The evidence is not fully satisfactory regarding either of these points. The observations that have been made hardly establish the fact that an accumulation of the extractives is a feature of all or many cases of uræmia. The evidence is even less strong in regard to particular members of the extractive group.

Regarding the view which attributes the uræmic phenomena to the action of toxins, the poisonous basic products of bacterial activity, there is little to be said, for the evidence on which it is built, is scanty and conflicting. None of the toxic ptomaines that have been suspected in this connection have been found in the blood of uræmics.

The urea theory of uræmia. The evidence relating to urea as a factor in uræmia may be grouped in answer to the following queries: (1) Does urea occur in excess in the blood of uræmic patients? (2) Is urea toxic, and if so, to what extent does it explain the symptoms of uræmia? As regards the first question, we have a sufficiently large accumulation of observations made by competent investigators to enable us to reach a definite decision. In the blood of Bright's disease, the quantity of urea is largely increased beyond that found in the normal blood, and its presence is readily detected even by imperfect chemical methods. When we come to the second question, we find that the facts which favor and those which oppose the idea that urea is toxic seem to be about evenly balanced. Dr. Herter then reviewed the observations that have been made bearing on this question, and detailed a number of experiments made by himself which go to prove that pure urea injected into the blood of the dog and monkey in large amount is in the highest degree toxic. The autopsies in these cases disclosed marked congestion of the gastro-intestinal tract. To what extent and under what conditions urea is a factor in uræmia, the author said it was not possible for him to state at the present time. Facts at our command strongly favor the view that the gastro-intestinal symptoms of uræmia are due to urea. There is no doubt that we at present group together under the term uræmia, conditions which are totally distinct as regards pathology. The evidence is very strong, though not quite conclusive, that one group of symptoms depends largely on the accumulation of urea, and perhaps extractives in the blood, while another set of symptoms bears the stamp of an infective process operating in the presence of renal insufficiency. Observations may show that even further subdivisions of cases are necessitated by pathological considerations.

It is upon the following facts that the author based the view that urea plays an important part in causing the gastro-intestinal symptoms of uræmia:

(1) The presence of urea in excess in the blood in such cases.

(2) The property which pure urea possesses of causing such symptoms when injected in the circulation.

(3) The occurrence in Bright's disease of congestion of the gastro-intestinal tract, and the occurrence of a similar congestion in animals which is positively due to the injection of urea into the blood.

(4) The fact that urea is found in the dejecta of patients with gastro-intestinal uræmia.

(5) The absence in many of these cases of any elevation in temperature, or other evidence of acute toxæmia.

(6) The fact that the urine in these cases, even at the time of the crisis, is no more toxic than normal urine, which is in sharp contrast to the very toxic urines found in acute febrile uræmias of cerebral type.

Dr. W. H. THOMSON said the subject of uræmia has always been and still remains a very mixed one in his mind. Dr. Herter's paper is certainly a very valuable contribution to the subject. The cases of uræmia to which Dr. Herter principally confined himself—those in which the characteristic symptoms are vomiting and purging—form comparatively a small minority of those that come under our observation. In many cases there are no gastro-intestinal symptoms whatever. Theoretically, Dr. Thomson said, he still felt strongly inclined to the view that toxins play a very important part in the production of the purely nervous symptoms of uræmia. Regarding the experiments performed by Dr. Herter in order to prove the toxic effects of urea, Dr. Thomson inquired whether the injection into the blood of sodium chloride or other similar substances might not give rise to derangements of the system to some degree resembling those produced by the repeated and rapid introduction of increasing quantities of pure urea.

Dr. SACHS expressed the hope that the critics of the future would deal more leniently with Dr. Herter's theory than he had dealt with the theories reviewed in his paper, and that they would expend the same amount of thought and labor to prove their assertions. He did not think that any one should attempt to establish a single theory to explain such a complex of symptoms as we have in uræmia. Very much the same symptoms occur under other conditions, and we are perfectly willing to recognize the different morbid processes giving rise to them.

Dr. HERTER then closed the discussion. He stated that in his paper he did not advocate any one theory to explain all the phenomena of uræmia. What he did advocate was that there is a certain class of symptoms, a limited class, namely, the gastro-intestinal symptoms, which are met with in certain cases of uræmia, and which are due, in all probability, to urea. The proof of this is not absolutely satisfactory, but he did not see how the proofs adduced by his experiments could be interpreted in any other light. In reply to Dr. Thomson's question, Dr. Herter said that large quantities of sodium chloride can be injected into the blood without producing symptoms comparable to those produced by the introduction of urea. As regards the cerebral symptoms of uræmia, he does not know what they are due to, and in his paper, he made no attempt to throw any light on those cases. The autopsies on the animals which were killed by the introduction of urea were performed immediately after death, and the intestinal congestion was very marked.

ELECTION OF OFFICERS.

The following officers were elected for the ensuing year: President, Dr. E. D. Fisher; Vice-President, Dr. C. A. Berter; Second Vice-President, Dr. W. M. Leszynsky; Recording Secretary, Dr. Frederick Peterson; Corresponding Secretary, Dr. Mary Putnam Jacobi; Treasurer, Dr. G. M. Hammond.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, MAY 17, 1894.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

HEART-FAILURE.

It has again and again been pointed out that the term heart-failure, though unfortunately too often used by physicians in their death returns is vague and indefinite, conveying no information, though possibly convenient to cover ignorance—being applicable to every alteration of the cardiac mechanism, whereby death results. Thus, heart-failure may be due to influences of a nervous kind—shock, inhibition through the pneumogastric, paralysis by narcotics or sedatives. Bouillaud relates an instance of a previously healthy man who died of syncope in a fright. Lancereaux, in a recent treatise, reports several cases of sudden death in previously healthy persons from violent excitation of the pneumogastric. In two of these cases, attacks of indigestion paralyzed the vagus centre.¹ "In both these patients," he says, "death supervened after a hearty meal, from syncope, as was proved by the empty heart-cavities, and the absence of any material disorder or lesion capable of explaining the cause of the death; every thing, moreover, went to show that the syncope was due to an overloaded stomach." To this category he referred the sudden death which often follows a blow on the epigastrium, or even the excessive drinking of cold water (reflex paralysis of heart through vagus excitation). Moreover, the sudden death which sometimes takes place in the course of pleurisy or pulmonary tuberculosis may be due to irritation of the vagi, "especially in those cases where the almost complete emptiness of the heart's cavities indicated death by syncope."² This conclusion is in accordance with some decisive experiments of Brown-Séquard and Paul Bert. Much more frequent is heart-failure from toxic, inflammatory and degenerative changes in the myocardium, from acute dilatation due to nutritive disturbances or to exhaustion from overwork.

The toxic lesions of the myocardium have been arranged under the heads of: (1) toxic, (2) pyretic myo-

carditis.³ Myocarditis toxic is the effect of poisoning by alcohol, phosphorus, arsenic, mercury, lead, etc. This affection manifests itself by a diminution of the muscular power of the heart. The organ, without presenting changes appreciable to palpation and percussion, "gives a feeble impulse and muffled beats." In poisoning by mercury, the heart is "flabby, soft, and friable, of a dirty gray or yellowish color; in poisoning by phosphorus, it is tumefied, mottled with purpuric spots, and is pale yellow or orange yellow." "The muscular fibre in the one case is pigmented and granular; in the other, it is the seat of a transformation which, to the microscope, manifests itself by the presence of granules which are strongly refractive and soluble in ether." Many pathologists, denying the existence of parenchymatous myocarditis would regard these lesions as simple parenchymatous and fatty degeneration.

Pyretic or infectious myocarditis is sufficiently common as a complication of cholera, yellow fever, diphtheria, small-pox, malignant scarlet fever, typhoid fever, etc. The heart-muscle is poisoned by the pyretogenous agent, becomes fatty and flabby, its pulsations are feeble and obscure; the pulse is small, irregular and accelerated; syncopal states are frequent, and are the cause of the sudden death so common at the close of grave fevers. Bourges, who has studied the alterations of the heart-muscle in malignant diphtheria, remarks that it is generally augmented in volume, "dilated, but not hypertrophied," "of a dead-leaf color." "When you dissociate the muscular fibres, you note their great fragility; they are tumefied and granular; may in fact undergo two kinds of degeneration, the granulo-fatty and the vitreous. Bourges also points out the fact that there are also sclerotic changes, so that it may be said that the diphtheria-poison "determines at the same time parenchymatous and interstitial lesions."⁴

Suppurative myocarditis, from septic infarcts in the walls of the heart (a complication of pyæmia and septicæmia); and acute interstitial myocarditis existing independently or following rheumatic pericarditis and endocarditis (also sometimes of syphilitic origin) are potent causes of heart-failure.

G. C. Henderson, in the "Transactions of the Pathological Society," London, 1883, gives an interesting report of a case of gummatous myocarditis followed by death; the interventricular septum and anterior wall were the seat of syphilitic nodules surrounded by sclerous rings which had extensively invaded and destroyed the muscular tissue. Hilton Fagge publishes a series of cases of "fibroid disease of the heart," and Dr. A. L. Loomis⁵ would make of "cardiac fibrosis" ("arterio-sclerosis of the heart") one of the most common causes of heart-failure. He believes that obstructive changes in the aorta and at the origin of the coronary arteries are most usually associated with fatty degeneration, while fibroid changes are associated with

obstruction in the coronary arteries. This distinction appears to us well made.

Fatty degeneration of the myocardium, besides being a sequel of toxic and pyretic myocarditis (*vide supra*) follows wasting diseases, chronic anæmia and especially pernicious anæmia, and, notably, stenosis of the coronary arteries by which the nutritive supplies of the heart-muscle are cut off. It is a final stage in compensatory hypertrophy from Bright's disease, and in chronic valvular disease, whether stenosis or insufficiency. The heart-muscle, though the most untiring of all muscles, is perhaps the most prone to fatty degeneration. Certainly, persons affected with chronic valvular disease, with hypertrophy, or with hypertrophy from renal sclerosis, can expect unbroken compensation for only a limited number of years, and sooner or later, from complex causes, the overworked heart-muscle fails and becomes granular and fatty.

Acute dilatation without hypertrophy and without visible degeneration of the myocardium in its connection with heart-failure has been studied by Dr. John Curnow in two recent lectures.⁶ Naturally, he says, the symptoms of cardiac failure due to a primitive dilatation of the heart-cavities from insufficient nutrition are precisely the same as those due to a failure in compensatory hypertrophy subsequent to any grave circulatory obstruction. In the early stage, they are pallor, palpitation, headache and dyspnoea on exertion, with often a distressing angina. As the disease advances, there is lividity and œdema, and the pulse is small, irregular and rapid. Dilatation occurs to a limited extent in anæmia and chlorosis, in fatal cases of leukæmia, pernicious anæmia and chronic malaria. A form of cardiac dilatation frequently follows typhus and typhoid fever; the weakened walls of the heart readily give way, and distention occurs under the influence of ordinary tranquil work. Curnow, in the lectures referred to, gives examples of acute dilatation accompanying chronic malaria, beri-beri and scurvy.

The influence of overwork or overstrain in producing acute dilatation and sometimes complete cardiac failure was alluded to in a former number of the JOURNAL.⁷

That sudden death may result by paralysis or rupture from excessive strain and overfilling of the heart-cavities is by no means a very rare experience. Nevertheless, as Dr. A. L. Loomis⁸ well remarks, "it is safe to assume that heart-failure is impossible so long as the heart-cavities are of normal size, the heart-muscle of normal integrity, and the cardiac innervation not seriously disturbed, the function of the trophic nerves being normal."

To sum up, when physicians report cases of death as due to "heart-failure," it may be assumed that the "heart-failure" was due either to some overpowering nervous influence or to toxic, inflammatory or degenerative changes in the myocardium; or to suppurative or interstitial myocarditis; or to arterio-sclerosis of the

heart; or to fatty degeneration following wasting disease, valvular disease, or stenosis of the coronary arteries; or to acute primitive dilatation from prostrating fevers, chlorosis, leukæmia, pernicious anæmia, chronic malaria, overwork and other depressing influences!

At the meeting of the Climatological Society held at Richfield Springs, N. Y., in 1892, Dr. F. I. Knights, in discussing Dr. Loomis's paper, made the remark that a certificate of death from heart-failure was little different from one of death from want of breath. Entering deaths as due to "heart-disease" is amenable to almost the same objection, but certificates are returned in this manner by reputable physicians every day.

THE RÔLE OF THE NOSE IN ZOLA.¹

FOR a long time the study of "artistic anatomy," so called, has been recognized as a necessary and proper training for an artist or sculptor. Latterly, there has arisen what may be styled a study of literary physiology. The analytical and realistic school of writers fill their books with outspread dissections of the human body no less than of its soul, and remove the covers from society as from a watch to "show how the wheels go round."

The latest aspect of this physiological-romance writing is the discovery by a Frenchman that great writers depend largely upon some special sense for remembrance and reproduction of emotions, sensations and experiences. "Zola," says M. L. Bernard in his essay upon "*Les odeurs dans les romans de Zola*," "has more than any other man lived, suffered and revelled in the sense of smell," and he offers us accordingly a study of the smells in Zola's stories. But first we must begin with the nose of the master.

"In all the portraits of Zola which I have seen it was the nose which struck me first. The forehead is broad and well uncovered, circled with short, trimmed locks; the beard is thick-set, with short, bristling hairs; the glance is cold and piercing, though a little softened by the lenses of his glasses; the lips and mouth are so hidden under the moustache as to lose half their expression; but there is the nose alone in the full light of the mid-face. It is large, fleshy, broad, pierced by two great nostrils, which seem to quiver and inhale the air. Only to see this mighty nose explains all the associating descriptions of odors so well known throughout his books." Being gifted with such an olfactory organ, it is not to be wondered at that "Zola is the creator of a new terminology, of a language of odors, and that he leads his readers to study to analyze and classify them, to seize upon their secret harmonies, their mysterious relations to sentiments and ideas, their silent but irresistible influence upon resolve and conduct." Every page, and often every line, is marked by this masterly peculiarity.

Open any of his books, and examples are at hand. In "*L'Assommoir*" we find "the soapy odor," "the heavy, stale odor of the wash-house of Rue Neve

⁶ Lancet, January 6, 13, 1894.

⁸ Proceedings of the Climatological Association, 1892, p. 72.

¹ Gazette des Hôpitaux, No. 46, 1894.

made much of; the odor of old dust and sour filth in Lorilleux's room." Each character has a perfume *sui generis* belonging to his age, sex, state of health, godly or vicious habits. So in "Pot-Bouille," "Bachelor exhales an odor of vulgar debauchery," "Madame Campardon, a fair odor of fresh autumn fruit," and "Nana, an odor of life, of all-powerful woman, which intoxicates one."

In other books we find the abbé with his "odor of a priest, of a man made unlike others." "The ruins of a house have an odor of damnation." We must admit we have smelt this odor in houses which were not in ruins or uninhabited.

Finally, in "Ventre de Paris," the swarming population of the Halles carries in every fold of its garments "an odor of spawn, one of those heavy odors which rises from the rushes and shiny lilypads when the eggs burst from the belly of the fish fainting from love in the sun."

Such is the interlinear study of the smells and stinks in Zola's books. Surely the study of literary physiology of special senses is but just begun. We may yet find a cipher which will disclose a system of acoustics in Gibbon, of visual physiology in Cervantes, of tactile sensibility in Thackeray; and since Scott's stag drank itself full, there is every chance that we may find between the lines of Marmion and Ivanhoe a detailed study of the sense of taste.

MEDICAL NOTES.

AN HONOR TO PROFESSOR VIRCHOW. — The King of Italy has conferred on Professor Virchow the Grand Cross of the Order of SS. Maurice and Lazarus.

A STATUE OF DR. SIMS. — A bronze statue of Dr. J. Marion Sims, by Du Bois, of Paris, has been completed, and will be erected in Bryant Park as soon as the pedestal is ready.

SMALL-POX AT NEW YORK QUARANTINE. — Two cases of small-pox were detained at quarantine in New York Harbor on May 10th, from the steamer *Roland* from Bremen.

A PHYSICIAN'S GENEROUS BEQUEST TO NURSES. — The late Dr. S. J. Moore, of Glasgow, has bequeathed the residue of his estate, after the payment of other legacies, etc., to found a convalescent home for nurses, to be called by his name. The amount of the bequest is likely to be over \$200,000.

ONE HUNDRED AND FIVE YEARS OLD. — According to the *Journal of the American Medical Association*, Mrs. Hannah Chard, of Glassboro, N. J., was one hundred and five years old on April 20th, having been born at Brandywine in 1789. She is still able to go out, and has one hundred and eighty grandchildren and great-grandchildren.

THE AMERICAN ASSOCIATION OF RAILWAY SURGEONS, at its annual meeting in Galveston, Texas, seems to have had a very lively experience over the election of its officers. Pandemonium reigned; every-

body had the floor and spoke at once; the presiding officer was helpless, and epithets were freely exchanged. No blood was shed. The Texas air was not responsible, for the trouble really dated from the preceding meeting.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — During the week ending at noon, May 16, 1894, there were reported to the Board of Health of Boston the following numbers of cases of acute infectious disease: diphtheria 51, scarlet fever 58, measles 16, typhoid fever 18, small-pox 1. There is one case of small-pox at the Canterbury Street Hospital, and three cases at Gallop's Island; no deaths. During the week the State Board of Health received reports of the following cases of small-pox: Holyoke 1, Worcester 1, Chicopee 1, Randolph 1, Chelsea 1.

SMALL-POX IN PROVIDENCE. — A fourth case of small-pox was discovered last week in Providence, which, like the three of a previous week, has not yet been traced to any origin of infection.

BOSTON CITY HOSPITAL. — Mr. A. Shuman has been re-elected President of the Board of Trustees of the Boston City Hospital, and Mr. H. H. Sprague has been re-appointed on the Board. The Board has requested of the City Government a special appropriation of \$330,000 for various much-needed purposes not provided for by present funds and contracts.

SUFFOLK DISTRICT MEDICAL SOCIETY. — The Censors' examination of the Suffolk District Medical Society will be held on June 7th, at 2 P. M., at 19 Boylston Place. The Censors of the Suffolk District officiate for the Society at large, and candidates are requested to make personal application to the Secretary three days before the meeting.

PROGRESS OF THE MEDICAL REGISTRATION BILL IN THE MASSACHUSETTS LEGISLATURE. — In the House last week the Senate Bill to regulate the practice of medicine was passed to a third reading, a substitute bill, offered by Mr. Hayes of Lowell, to punish persons illegally using the designation "M.D." being rejected.

A RESIDUARY LEGACY TO THE CAMBRIDGE HOSPITAL. — The will of Jacob B. Remick, of Cambridge, leaves his estate in trust during the life of certain persons named; but upon their death the entire estate is to be converted into cash, one-third of which is to be given to the Cambridge Hospital. The value of the bequest is about ten thousand dollars. The Avon Home and the Old Ladies' Home of Cambridge receive the other two-thirds.

NEW YORK.

OPENING OF THE NEW POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL. — On the afternoon of May 8th, a public reception was given at the new Post-Graduate Medical School and Hospital, and in the evening the formal opening exercises of the institution took place. The Secretary, Dr. Clarence C. Rice,

read a report giving the history of the school, and addresses were made by the President, Dr. D. B. St. John Roosa, the Rev. William R. Huntington, D.D., and St. Clair McKelway, Esq., of Brooklyn.

SEIZURE OF TUBERCULOUS BEEF.—On the 7th of May the meat inspectors of the Board of Health seized the carcass of a cow affected with tuberculosis, which had been cut into quarters, but not yet hung up for sale, at West Washington Market. It was found that the carcass had been shipped from Goshen, Orange County, by a milk-dealer and stock-raiser by the name of Smith, and Dr. Johnson, the veterinary surgeon to the Health Department, is making an investigation of the case. Pending his report, the Board has ordered that all meat and milk from Smith's farm shall be seized when it reaches the city. Several carcasses of tuberculous beef have lately been discovered in the markets, and it is feared that a whole herd of cattle, and possibly several herds, in Orange County may be infected with the disease.

A PENSION FUND FOR EMPLOYÉS OF THE HEALTH DEPARTMENT.—The Governor has signed the Lawson Bill, establishing a pension fund for the physicians, nurses, clerks and other employés of the Health Department who have served a term of twenty years, and also for the families of employés dying in the discharge of duty. The fund from which the pensions will be paid is to be made up of the fines and penalties collected for violations of the city health laws, and of the fees paid for searches of the records.

THE KILLING OF THE ELEPHANT.—The problem of how best to kill an elephant weighing over five tons has presented itself to the Park Commissioners during the past week. The animal known as "Tip," which was presented to the city some years ago by Forepaugh, the showman, has always been a vicious creature, and it was finally determined that for the safety of the keepers at the Central Park Menagerie and of the general public it would be advisable to destroy him. Poison was selected as the most satisfactory means of accomplishing this object; and Dr. George S. Huntington, of the College of Physicians and Surgeons, was asked to take charge of the killing. Cyanide of potassium was determined upon, and the attempt was first made to give it to the elephant concealed in carrots and apples. He quickly detected the bitter taste, however, and ejected the articles from his mouth. A half a loaf of rye bread with a cavity in it filled with the cyanide he also tossed from him. Finally, the expedient was tried of giving him the poison in capsules mixed with a bran mash, and this proved successful. Death occurred in a comparatively short time, and was evidently quite painless.

PHILADELPHIA.

THE UNIVERSITY OF PENNSYLVANIA will hold its commencements of all its departments during the first week in June.

JEFFERSON COLLEGE held its commencement exercises May 9th, and graduated a class of 163. The

trustees conferred the degree of LL.D. upon Prof. William Goodell, M.D.

THE MEDICO-CHIRURGICAL COLLEGE graduated the largest class in its history on the 11th inst., 44 students receiving their medical degrees.

THE WISTAR INSTITUTE OF ANATOMY AND BIOLOGY will be opened May 21st with addresses by Professors Pepper, William Osler and Harrison Allen.

NEW WOMEN PHYSICIANS.—Fifty women received the degree of Doctor of Medicine at the commencement of the Women's Medical College of Pennsylvania last week.

Miscellany.

OUT-PATIENT HOSPITAL ABUSE.

A PHYSICIAN sends to the *British Medical Journal* the following note from a patient, a tradesman with a good income, describing a bit of out-patient experience in Liverpool.

I called at the doctor's residence, and was told that he was at the Eye Infirmary, and would not be home for some hours. As I had not made arrangements to stay overnight, I said I could not wait so long, and was recommended to go and see him at the infirmary. I did so, and found myself in a room with about 150 or 160 other persons, mostly, so far as I could judge, working-class people like myself and in easy circumstances. Looking around I recognized an old friend of mine from Blackburn, and asked him what on earth he was doing there. He said he came up regularly to have his eyes looked after. "Why," I said, "you could afford to pay this man a guinea every time, couldn't you?" "Yes," said he; "but what is the use of being such a fool as to throw away your guineas when this chap will see you for nothing?"

It might not be impossible to repeat the same experience at many hospitals in this country, and as the number increases so will the abuse.

PERMANGANATE OF POTASH IN OPIUM POISONING.

DR. WALTER L. PYLE¹ reports from the Emergency Hospital of Washington, D. C., four cases of opium poisoning in which permanganate of potash was administered. Although the conditions under which the cases were treated and the considerable use of other restoratives make the results of no conclusive value, the report of all such cases is much to be desired.

There was one fatal case, a man fifty-seven years old, who had taken an unknown number of morphine pills, each containing one-eighth of a grain. He was brought to the hospital about five hours after the supposed time of taking the poison. Permanganate of potash was given by mouth and hypodermatically. Two hours later the conjunctival and plantar reflexes returned for a while, but the man died seven hours after entrance.

A man twenty-two years old took three teaspoonfuls of sulphate of morphia; treatment was begun thirty minutes later. He was given strychnine, atro-

¹ Medical News, May 12, 1894.

pine, caffeine and coffee, and the permanganate of potash, six grains to a pint of water, was given by stomach and subcutaneously. In eight hours he was considered out of danger, and the next day was discharged well.

The other two patients were women, aged twenty-five and twenty-one years, who took respectively half an ounce and two drachms of laudanum. In each case atropine was used, and the permanganate was given by mouth within a very short time, and a little later subcutaneously. A few hours sufficed to put both women out of danger.

OBITUARY.

ALBERT CUSHMAN STANARD, M.D.

THE following resolutions were passed at the last regular meeting of the Harvard Medical Society of New York:

Whereas, Dr. Albert Cushman Stanard, an esteemed member of the Harvard Medical Society of New York, has in the infinite wisdom of God been called thus early to lay aside the duties of life, cut down in the vigor of early manhood, as the paths of usefulness and promises of prosperity were opening wide to him. Therefore, be it

Resolved, That in his untimely death we recognize the loss to the Society of one of its most promising and worthy members, and desire to pay to his memory a tribute of sincere respect;

Resolved, That we extend to his stricken sisters our heartfelt sympathy at the grief which has come upon them;

Resolved, That these resolutions be published in the *Boston Medical and Surgical Journal*.

[Signed.] JOHN B. WALKER, M.D.
JOHN H. HUDDLESTON, M.D.
WILLIAM B. COLEY, M.D.

Correspondence.

THE AMERICAN MEDICAL ASSOCIATION.

The following letter has been received through Dr. H. O. Marcy:

BOSTON, May 2, 1894.

DEAR SIR:—I take pleasure in advising you that the Chicago and North-Western Railway Co. have made arrangements for an excursion rate for physicians attending the San Francisco meeting of the American Medical Association. The fare from Boston to San Francisco and return will be \$125.

A palace-car will leave Boston at 2 P. M., Monday, May 28th, via Boston & Albany, New York Central & Hudson River, and Lake Shore & Michigan Southern Railroads, connecting at Chicago, where a through palace-car will be provided, leaving Chicago at 10.30 P. M., Tuesday, May 29th, via Chicago & North-Western, Union Pacific and Southern Pacific Railroads.

Diagrams of sleeping-cars will be in this office, No. 5 State Street, Boston, and berths reserved from Boston to Chicago, and similar accommodations assigned, from Chicago to San Francisco. The price of berths, Boston to San Francisco will be \$21.

Holders of these excursion tickets, will, on payment of \$15 extra, previous to departure from Missouri River (on going trip) be permitted to return via Portland and Union Pacific Railway, or any of the direct Northern routes.

Tickets are valid for return until July 15, 1894. If any extension of time or reduction of rates are made, I will, with pleasure, promptly advise of same.

Remittance may be made to this office to cover cost of tickets and sleeping-car berths.

Yours very truly,
J. E. BRITAIN, N. E. P. Agent.

METEOROLOGICAL RECORD.

Deaths reported 2,551: under five years of age 836; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fever) 373, acute lung diseases 363, consumption 302, diphtheria and croup 148, diarrhoeal diseases 42, measles 37, whooping-cough 35, scarlet fever 33, cerebro-spinal meningitis 29, typhoid fever 25, small-pox, erysipelas and malarial fever 8 each.

From whooping-cough New York 11, Philadelphia and Brooklyn 4 each, Boston, Washington and Cincinnati 3 each, Cleveland and Taunton 2 each, Nashville, Fall River and Cambridge 1 each. From scarlet fever New York 19, Boston 5, Brooklyn 3, Philadelphia and New Bedford 2 each, Cleveland and Holyoke 1 each. From cerebro-spinal meningitis New York 12, Washington, Cleveland and Holyoke 4 each, Brooklyn, Somerville, New Bedford, Chelsea and Pittsfield 1 each. From typhoid fever Philadelphia 6, Brooklyn 5, Cincinnati and Somerville 3 each,

New York, Boston, Charleston, Worcester, Lowell, Cambridge, Springfield and New Bedford 1 each. From small-pox New York 4, Brooklyn 3, Holyoke 1. From erysipelas New York 4, Philadelphia 2, Washington and Amesbury 1 each. From malarial fever New York 3, Brooklyn 2, Philadelphia and Charleston 1 each.

In the thirty-three greater towns of England and Wales with an estimated population of 10,458,442, for the week ending April 21st, the death-rate was 18.2. Deaths reported 3,054: acute diseases of the respiratory organs (London) 304, measles 192, whooping-cough 117, diphtheria 79, scarlet fever 60, diarrhoea 31, fever 29, small-pox (London 4, Birmingham 3, West Ham 2, Manchester 1) 10.

The death-rates ranged from 11.9 in Portsmouth to 26.4 in —; Birmingham 20.2, Bradford 17.9, Croydon 13.0 Derby 15.8, Huddersfield 16.4, Leeds 16.6, Liverpool 14.7, London 18.1, Manchester 19.2, Newcastle-on-Tyne 16.5, Nottingham 16.3, Sheffield 15.3.

In the thirty-three greater towns of England and Wales with an estimated population of 10,458,442 for the week ending April 28th, the death-rate was 18.3. Deaths reported 3,665: acute diseases of the respiratory organs (London) 255, measles 203, whooping-cough 148, diphtheria 77, scarlet fever 58, diarrhoea 28, fever 26, small-pox (Birmingham 9, London 6, Portsmouth 3) 18.

The death-rates ranged from 11.0 in Portsmouth to 25.9 in Oldham; Birmingham 22.5, Bradford 17.5, Derby 12.7, Leeds 16.2, Liverpool 25.6, London 18.5, Manchester 20.9, Nottingham 18.2, Sheffield 16.3.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 5, 1894, TO MAY 11, 1894.

CAPTAIN WILLIAM G. SPENCER, assistant surgeon, will report in person to the president of the Army retiring board at Omaha, Nebraska, at such time as he may designate, for examination by the board.

Leave of absence for two months to take effect on or about July 1, 1894, is granted MAJOR WILLIAM E. WATERS, surgeon, U. S. A.

A board of medical officers to consist of MAJOR JOSEPH K. CORSON, MAJOR VALERY HAVARD and MAJOR EDWARD B. MOSELEY, surgeons, is appointed to meet at West Point, New York, June 1, 1894, or as soon thereafter as practicable, for the physical examination of the cadets of the graduating class at the U. S. Military Academy and such other cadets of the Academy and candidates for admission thereto, as may be ordered before it.

CAPTAINS GEORGE H. TORNEY and LOUIS W. CREAMPTON, assistant surgeons, will report in person to COLONEL CHAS. H. ALDEN, assistant surgeon-general, president of the examining board appointed to meet at the office of the surgeon-general, U. S. A., on Tuesday, May 8, 1894, at such time as they may be required by the board for examination as to their fitness for promotion.

Leave of absence for twenty days to take effect on being relieved from duty at David's Island, N. Y., is granted MAJOR JOS. R. GIBSON, surgeon.

FIRST-LIEUT. BENJAMIN L. TEN EYCK, assistant surgeon, now on temporary duty at Fort Clark, Texas, is assigned to duty at that post.

FIRST-LIEUT. WILLIAM F. LIPPITT, JR., assistant surgeon, is relieved from duty at Camp Eagle Pass, Texas, and ordered to Fort Leavenworth, Kansas, for duty.

Paragraph 2, S. O. No. 86, April 12, 1894, A. G. O., assigning FIRST-LIEUT. HARLAN E. MCVAY, assistant surgeon, to station at Angel Island, Cal., is revoked. He will be relieved from duty at Fort Huachuca, Arizona, and will report for duty at the Presidio of San Francisco, Cal., relieving FIRST-LIEUT. CHARLES WILLCOX, assistant surgeon, who, after being thus relieved, will report for duty at Angel Island, Cal.

FIRST-LIEUT. JOHN S. KULP, assistant surgeon, is relieved from duty at Fort Sheridan, Illinois, and ordered to Fort Spokane, Washington, for duty.

FIRST-LIEUT. GEORGE M. WELLS, assistant surgeon, will proceed to Fort Bowie, Arizona Territory, and report for temporary duty not later than the 15th inst., during the absence on leave of CAPTAIN JEFFERSON D. POINDEXTER, assistant surgeon.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING MAY 12, 1894.

R. A. MAHMION, surgeon, will hold himself to relieve Medical Inspector G. A. BRIGHT, on the U. S. S. "Newark."

G. E. H. HARMON, surgeon, to the U. S. S. "Monongahela," June 15, 1894.

W. M. BARNUM, assistant surgeon, to the U. S. S. "Monongahela," June 1, 1894.

J. M. STEELE, surgeon, from the U. S. S. "St. Louis" and to League Island Yard.

H. G. BEYER, surgeon, from Naval Academy and to the "Bancroft."

CLEMENT BIDDLE, passed assistant surgeon, from League Island Yard and to Marine Rendezvous, Philadelphia, Pa.

J. F. LEYS, assistant surgeon, with one month's leave with permission to go abroad.

SOCIETY NOTICES.

BOSTON MEDICAL ASSOCIATION.—The annual meeting of the Boston Medical Association will be held Monday afternoon, at 4 o'clock, May 21st, at the Boylston Medical Library, 19 Boylston Place.

This Association, founded in 1806 for the maintenance of a proper fee table, should be known and joined by every member of the Massachusetts Medical Society residing in Boston.

CHARLES L. SCUDDER, M.D., Secretary.

AMERICAN ORTHOPÆDIC ASSOCIATION.—The eighth annual meeting will be held in Washington, D. C., Tuesday, Wednesday, Thursday and Friday, May 29th, 30th, 31st and June 1st, inclusive.

The Sessions will be held in the Preparatory Department, Columbian University, H near 14th Street.

The Annual Dinner will be omitted and instead a Breakfast will be given by the outgoing President at 2 P. M., on Wednesday at the Shorham, to members of the Association. This will give the members an opportunity to attend the dinner of the General Congress on Wednesday evening, to which they are all invited.

The President's Address will be delivered on Wednesday after the Executive Session, on: "Orthopedic Surgery, of the Past and Future, and the Influence of Surgical Bacteriology and Modern Pathology upon the Subject."

There are forty-five papers already announced and the following discussions have been arranged:

First Day.—"Flat-Foot." (a) "Its Etiology and Mechanism of its Production." Newton M. Schaffer, M.D., New York. (b) "Pathology, Prognosis and Mechanical and Surgical Treatment." T. C. Morton, M.D., Philadelphia. (c) "Gymnastic Treatment." H. Augustus Wilson, M.D. Royal Whitman, M.D., New York; Sidney Roberts, M.D., Philadelphia; J. D. Griffith, M.D., Kansas City; Roswell Park, M.D., and others will take part in the discussion.

Second Day.—"Rachitic Deformities." (a) "Etiology, Clinical History and Lesions." A. Jacobi, M.D., New York. (b) "Its Various Manifestations, Diagnosis, Differential Diagnosis and Prognosis." Benj. Lee, M.D., Philadelphia. (c) "Mechanical and Constitutional Treatment." Samuel Ketch, M.D., New York. (d) "Operative Treatment." DeForest Willard, M.D., Philadelphia.

Third Day.—"Paralytic Deformities." (a) "Etiology, Clinical History and Pathological Conditions Producing Them." E. H. Bradford, M.D., Boston. (b) "Varieties, Diagnosis, Differential Diagnosis and Prognosis." E. G. Brackett, M.D., Boston. (c) "Mechanical Treatment." John Ridlon, M.D., Chicago; Joel Goldthwait, M.D., Boston. (d) "Operative Treatment, Paralytic and Rachitic Deformities." DeForest Willard, M.D., Philadelphia.

JOHN RIDLON, M.D., Secretary.

BOOKS AND PAMPHLETS RECEIVED.

Lecture.

URINARY DIAGNOSIS.¹

LECTURE II.

BY EDWARD S. WOOD, M.D.,
Professor of Chemistry, Harvard Medical School.

Albuminuria.—This term simply means the presence of albumin in the urine. It is not synonymous with Bright's disease, by which we mean one of the forms of organic disease of the kidneys; but, on the contrary, in the vast majority of the cases in which this symptom is present, it is due to some other pathological condition. The causes of albuminuria are very numerous and may be arranged in three principal classes, as follows:

- (1) Organic diseases of the kidneys.
- (2) Renal disturbances not due to organic disease.
- (3) Diseases of the urinary or genito-urinary passages attended with suppuration or hæmorrhage.

There is another class of cases in which the albuminuria is due to an altered composition of the blood in some diseases of the blood, but we need not consider such cases here since no examination of the urine is necessary in order to make a diagnosis of them.

We will first take up a study of the changes of the urine in the first, and by far the most important of the above classes of cases, namely, the organic diseases of the kidneys, which are sometimes grouped together under the general name Bright's disease. Of these organic diseases there are four which are quite distinct clinically, and the urinary secretion in these different affections has decidedly different characteristics, with the possible exception of the two most chronic forms, the interstitial and the amyloid degeneration of the kidneys, between which the differential diagnosis can generally be easily made by the clinical history and the physical examination of the patient.

In studying these diseases of the kidneys, I shall confine myself almost exclusively to the changes which are found in the urine, particularly those that are of diagnostic importance, and in referring to the different diseases, I shall use chiefly the terms of the English classification with which you are most familiar.

Acute Nephritis.—In this disease, also called acute Bright's disease, and acute parenchymatous nephritis, which consists chiefly of an acute inflammation of the membrane lining the renal tubules, the attack is usually sudden like that of other acute diseases, and is liable to follow exposure to cold, or to result from some infectious disease, such as diphtheria or scarlet fever. The urine suddenly falls in quantity to 400 or 500 c. c. in twenty-four hours, and often much less than this is passed. In the last case of severe acute nephritis, which I saw, the quantity was only 120 c. c. (4 fluid ounces) in forty-eight hours. The color changes to a smoky or deep black, and after settling we can see an abundant dark-brown sediment. The reaction is usually faintly acid. The specific gravity may be either higher or lower than normal. The absolute quantity of normal solids in twenty-four hours is much diminished, and the chlorine is generally totally absent or diminished to an exceedingly slight trace, during the early stage of the disease, while the dropsy is increasing. During this stage, which in cases that are to terminate favorably generally lasts

but a few days, the percentage of albumin is large, one-half per cent. or more. The maximum proportion of albumin reported in this disease is one and a half per cent.

The sediment in this early stage is seen upon microscopic examination to contain very numerous abnormal blood globules, by which I mean red corpuscles which have lost their contents by osmosis, and consequently their density, so that they have but little refrangibility, and have become swollen to a spherical form, their diameter being very much less than that of a normal corpuscle. In renal hæmorrhage, when the hæmorrhage is in the cortical portion of the kidneys, the blood corpuscles have almost universally this abnormal appearance. The sediment also contains numerous renal cells which are colored brown with decomposed blood pigment and are more or less granular, and the following variety of renal casts; epithelial, blood, brown-granular, fibrinous, simple granular and a few hyaline casts. By a fibrinous cast I mean the transparent, dense, highly refracting cast, which is colored brown or yellow; it is not composed of fibrin.

This is the condition of the urine during the early stage of acute nephritis while the inflammation is increasing or at its height, and the dropsy is increasing or at a standstill. If death occurs at this time, the kidney is what is called the large red kidney. As soon as the inflammation begins to subside, the character of the urine begins to change. The first change noticeable is the beginning increase in the daily quantity, and with this increase in quantity of urine, we see a corresponding diminution in the percentage of albumin. In acute nephritis, we may consider it the rule that, in the earlier stages of the disease, until the recovery of the kidney is nearly complete, the smaller the quantity of urine the larger the amount of albumin and *vice versa*. Also, with the beginning increase in quantity of urine, we find that the chlorine reappears or increases in amount, and the dropsy begins to diminish. As the quantity of urine increases, the color becomes less and less brown until, when the urine has reached about the normal, the color becomes slightly smoky.

From the beginning increase in the quantity of urine until it has reached about the normal amount, we find also a change in the character of the sediment. The blood globules, brown-granular and fibrinous casts gradually diminish in number; the proportion of hyaline and simple granular casts increases; and the number of brown-granular renal cells diminishes, most of them being free from color. At this time, which may be considered as the very beginning of convalescence, fatty renal cells appear; fatty elements (cells and oil globules) are seen on the casts; and fatty casts begin to be found. These fatty elements in the sediment increase gradually, until, in some cases, they may, for a day or two, form the predominating constituent of the sediment. They then gradually diminish and are found only in small proportion in the sediment of the urine in advanced convalescence.

If the case progresses favorably, without relapse or exacerbation, which is by no means the rule, the urine continues to increase, often very rapidly and with a correspondingly rapid diminution of the dropsy, from about the normal to two or three times the normal quantity, so that it may reach from two and a half to five litres (or quarts) in twenty-four hours. With the increase in the quantity of urine the color becomes pale, the smoky tint gradually disappearing; the

¹ Evening Lecture delivered at the Harvard Medical School, February 29, 1894.

specific gravity falls and the quantity of sediment becomes slight. The quantity of normal solids in the twenty-four hours may exceed the normal, since the urine contains not only the urea and other solids which are being formed in the economy at the time, but, in addition, those which were in the dropsical fluid. The albumin diminishes steadily with the increase of urine until it is present only in exceedingly slight traces. With the increase in the quantity of urine above the normal, the brown-granular, fibrinous, blood, fatty and epithelial casts gradually diminish and finally disappear; and we have in the sediment during the last few weeks of convalescence, only a very few blood globules and renal cells and a few hyaline and finely-granular casts, some of which have an occasional blood globule and renal cell attached. When the convalescence is nearly complete, the quantity of urine falls from the high point which it has reached, but without a corresponding increase in the amount of albumin, until it finally, with the complete restoration of the kidneys, reaches the normal, when the albumin and all of the abnormal constituents of the sediment disappear.

If an exacerbation occurs, and this is the rule rather than the exception, the quantity of urine suddenly falls to the normal or below, if the exacerbation be a severe one, and the color generally becomes more or less blood-red, the albumin increases again, and in the sediment we see an increase or a reappearance of the blood and epithelial casts. The blood globules, however, are almost invariably more nearly normal in character than in the first stage of the disease, and the blood pigment is not so much decomposed. This accounts for the blood-red color of the urine instead of the brown which we saw in the early stage. In some cases, during the progress of acute nephritis, several exacerbations may occur owing to some exposure to cold, errors in diet, or other causes, and in some cases the convalescence may be prolonged from one and one-half to two years before the kidneys become completely restored to a healthy condition, and the albumin and casts entirely disappear.

Subacute Nephritis, commonly called chronic parenchymatous nephritis, and also chronic tubular nephritis, may result from the acute disease, but it is more often chronic from the beginning, and frequently accompanies chronic wasting diseases, such as phthisis, syphilis, etc. In this disease, we find the so-called large white kidney after death. In this form of Bright's disease, the character of the urine varies according to the activity of the process going on in the kidneys. If the parenchymatous inflammation is active, the general dropy increases and, on simple inspection, the urine looks like that of a fever urine. The quantity passed in twenty-four hours is much diminished, generally from 400 to 600 c. c., but it may be much less than this. It is very high in color, not brown or bloody, of very high specific gravity, generally 1,026 to 1,030, very acid in reaction, and generally contains an abundant sediment, which is seen to consist chiefly of amorphous urates, as in many fever urines. The normal solids are relatively increased, with the exception of the chlorine, which is much diminished and may be nearly absent, if the dropy is increasing; but the daily quantity of solids is found upon quantitative estimation to be decidedly less than the normal. In the active stage of this disease the urine contains a larger proportion of albumin than in

any other kidney affection; generally the proportion is about one per cent., but it may reach as high as two or even five per cent. The sediment during this stage usually consists chiefly of amorphous urates, which should be removed before examining for the other constituents. This is done by allowing the urate sediment to settle, decanting the supernatant urine and adding to the sediment a considerable volume of lukewarm water, which will dissolve the urates and hold them in solution. The organized constituents will then settle, and may be seen as a rather heavy white deposit, which consists of numerous hyaline, granular and fatty casts, granular and fatty renal cells, and compound granule cells. It is rare to find any blood; and when blood occurs it is due, in my opinion, to a complication with acute nephritis.

Almost invariably, in this affection, owing to care or to appropriate treatment, an amelioration in the severity of the symptoms takes place, dropy diminishes and the other severer symptoms subside, and it is evident that the process going on in the kidneys is more or less inactive. When this occurs, the urine has an entirely different character. It is passed in larger quantity, but is still less than normal, generally from 1,100 to 1,300 c. c.: it is pale in color, of low specific gravity (1,010 to 1,015) slightly acid in reaction, and contains a considerable quantity of white sediment. The normal solids are diminished both relatively and absolutely. The albumin is less than in the active stage, but is still present in considerable quantity, from one-quarter to one-half per cent. The sediment is found to contain the same constituents as in the active stage, with the exception of the amorphous urates, but in smaller proportion, namely, hyaline, granular and fatty casts, granular and fatty renal cells, and compound granule cells.

In the latter stages of this disease, whether the process be active or not, we find for some months before death, in addition to these constituents, the so-called waxy cast, which is a transparent, dense, highly refracting, colorless cast. The waxy cast resembles the fibrinous cast seen in acute nephritis in every way, except that it is absolutely free from color. During the progress of a case of subacute nephritis we often see these two conditions of the urine alternating with each other a considerable number of times.

Chronic Nephritis (Interstitial).—This is the most insidious of all of the forms of Bright's disease. It has generally existed a long time before the physician is consulted and the urine examined. Some cases have, apparently, been traced to chronic lead-poisoning and malaria as a cause; but in most cases no definite cause can be assigned. After death from this form of kidney disease, we find the red, granular, contracted kidney; and in almost all cases there is also found hypertrophy of the left ventricle of the heart.

The urine is increased in quantity more or less, according to the advancement of the disease until the very latest stage, and is always more or less dilute unless complicated with some acute disease. From the beginning the urine gradually increases until it may reach four or even six litres (quarts) in twenty-four hours. But this increase is very gradual since the duration of the affection may be ten or even twenty years. The reaction is normal, the color at first normal, gradually becomes pale; the specific gravity gradually diminishes until it reaches 1,005 or 1,006; and the amount of sediment is slight, nor-

mal or less than normal. The normal solids are diminished relatively and absolutely according to the extent of the disease, except the indoxyl, which may be increased. The albumin varies from the slightest trace up to about one-quarter per cent. The sediment, up to the latest stage, consists only of hyaline, finely-granular, and granular casts. Towards the close of life the urine begins to fall until it is secreted in less than the normal quantity, but the specific gravity and the relative quantity of solids remains the same as when the amount of urine was large, so that the twenty-four hour quantity of solids is very much diminished. We may have only 400 or 500 c. c. of urine with a specific gravity of only 1,004 or 1,005, and in this final stage we may find only a very slight trace of albumin. The sediment at this time generally contains waxy casts in addition to the hyaline and granular casts. In this form of Bright's disease, the quantity of urine secreted at night is apt to far exceed that secreted during the day-time. The quantitative estimation of the urea is of very great value in this disease, since after the very earliest stage the twenty-four hour amount of the urea is diminished below the normal, and continues to diminish with the progress of the disease.

Amyloid Degeneration of the Kidneys.—This condition of the kidneys accompanies many wasting diseases such as suppurative diseases of the bones, phthisis, syphilis, etc., and when it exists in the kidneys, other organs, especially the liver and spleen, are usually found to be affected by it. It is very apt to be complicated with subacute nephritis, since both of these affections may be caused by similar conditions. The urine in amyloid degeneration resembles that of chronic interstitial nephritis, and from the urine alone it is impossible to make a differential diagnosis between these two forms of kidney disease. In amyloid degeneration, however, since the disease is primarily one of the blood-vessels and the secreting structure is only affected later, although the quantity of urine is increased to the same extent as in interstitial, the solids are not diminished in the same proportion, and hence the specific gravity is not as low, as a rule. In this disease, the urine steadily increases until it may reach three or four litres (or quarts), and the specific gravity correspondingly diminishes. The solids are also diminished relatively, but a quantitative estimation of the amount of normal solids in twenty-four hours, shows that they are more nearly normal in quantity than in interstitial nephritis. The albumin is only present in the urine in the very slightest trace at the beginning of the disease, but it gradually and steadily increases as the disease advances, and may reach one-half per cent. or more, especially if, as is usually the case, it be complicated with parenchymatous inflammation. The sediment is composed of hyaline and finely-granular casts, and in some instances of waxy casts also. If there is any parenchymatous inflammation we will find, in addition, fatty cells and casts.

Complications.—All of the above forms of disease of the kidneys are liable to be complicated, either with each other or with one of the hyperæmias, active or passive. Acute nephritis is especially apt to occur during the progress of any of the chronic forms, in which case, the quantity of urine will fall to an extent corresponding to the severity of the acute attack, and we will find the blood elements, globules and casts, in the sediment. Of the other forms of kidney disease,

the most important complication, and one of the most common, is the combination of the subacute (or chronic parenchymatous) with the chronic interstitial disease, which complication is called chronic diffuse nephritis. In this disease the interstitial element tends to increase the quantity of urine and the parenchymatous inflammation to diminish it, so that the daily amount of urine will be found to be largely increased if the interstitial disease predominates, and only slightly increased if the parenchymatous disease predominates. In the former case there will be but little albumin, and in the latter a comparatively large quantity. The sediment will naturally contain the hyaline and granular casts of both diseases, and the fatty elements, fatty casts, renal cells and compound granule cells of the subacute disease. The extent to which the kidneys are affected, or the amount of destruction of the kidney tissue, can be approximately estimated by the average daily amount of urea secreted. Subacute nephritis and amyloid degeneration are also very commonly present in the same case, since both conditions may be due to similar causes. The composition of the urine and sediment are practically the same as in chronic diffuse nephritis, and the two cannot be distinguished from each other by the urine alone.

In albuminuria caused by renal disturbances, which are not due to organic kidney disease, morbid growths, tubercular disease or calculi, the renal conditions are usually spoken of as active hyperæmia or irritation of the kidneys, and passive hyperæmia. I have considered these conditions elsewhere,² and will only refer very briefly here to the character of the urine. In the active hyperæmia or irritation of the kidneys, the chemical composition of the urine varies, so far as the physical properties and the normal solids are concerned, according to the cause. The urine may be either concentrated or dilute, and the daily quantity of normal solids may be normal or diminished. The albumin is always very small in quantity, usually being present in the very smallest traces except in the very severe cases, catarrhal nephritis, when we may have from one-eighth to one-quarter per cent. for a few days. This quantity of albumin does not persist, however, for more than two or three days unless it develops into an acute nephritis. The character of the sediment is usually that seen during convalescence from acute nephritis, and it is often impossible to distinguish by the urine alone between a convalescence from acute nephritis and an active hyperæmia of the kidneys. With the clinical history in addition, however, there is usually no difficulty in making the differential diagnosis.

In *Passive Hyperæmia*, the physical properties and chemical composition of the urine also vary according to the cause. The albumin is present always in the very smallest traces except in rare cases of passive hyperæmia of pregnancy, when it may reach nearly one-quarter per cent. I have known this quantity of albumin to be present in cases of pregnancy followed by eclampsia, when no chronic disease of the kidneys existed, as was proved by the subsequent history of the cases; and in these cases the comparatively large percentage of albumin persisted for two or three months before confinement. The sediment in passive hyperæmia is composed of pure hyaline and finely-granular casts only, so far as the renal elements are concerned.

² See Boston Medical and Surgical Journal, May 12, 1892.

RÉSUMÉ.

To sum up briefly, and looking at the subject from a little different point of view, we see from the above, that an abnormally large quantity of urine is passed in advanced convalescence from acute nephritis, in chronic interstitial nephritis, in amyloid degeneration of the kidney, generally in chronic diffuse nephritis, and in some cases of active hyperæmia of the kidneys. An abnormally small quantity of urine is passed in the early stage of acute nephritis, both active and inactive stages of subacute (or chronic parenchymatous) nephritis, generally in active hyperæmia, and always in passive hyperæmia of the kidneys. Toward death, of course, we find an abnormally small quantity of urine in all forms of kidney trouble.

A large amount of albumin, by which I mean one-half per cent. or more, is found in the urine only in the early stage of acute nephritis, the active stage of subacute (or chronic parenchymatous) nephritis, and, sometimes, in the chronic diseases complicated with these. A moderate amount of albumin, about one-quarter per cent. we find in early convalescence from acute nephritis, in the inactive stage of subacute (or chronic parenchymatous) nephritis, in advanced chronic interstitial disease and in amyloid degeneration of the kidneys, generally in chronic diffuse nephritis, for a few days in severe active hyperæmia (catarrhal nephritis), and in very rare cases of passive hyperæmia of pregnancy. Only very slight traces of albumin are found in advanced convalescence from acute nephritis, in the early stages of chronic interstitial and amyloid disease of the kidney, and, generally, in active and passive hyperæmia of the kidneys.

Blood is found in the sediment, free and adherent to the casts, and often with blood casts, only in acute nephritis and active hyperæmia, or other affections which are complicated with these. Fatty elements, fatty renal cells, fatty casts, or oil globules free and on casts, are found temporarily in acute nephritis, being most abundant in the early stage of convalescence; during the whole progress of a subacute and chronic diffuse nephritis, and in some cases of long-continued active hyperæmia of the kidneys, generally, however, in very small proportion in this last affection. The presence of calculi in the renal tissue, or the existence of cancer or other morbid growths affecting the kidney, produce more or less parenchymatous inflammation in those portions of the renal tissue affected, and we will consequently find on examining the urine and sediment in such cases some evidence of the parenchymatous inflammation. Generally, the urine resembles that of an active hyperæmia of the kidneys, but we may find in the sediment, in addition, crystalline elements, if there is a concretion, varying in character according to the nature of the concretion, or in cases of morbid growths rarely pieces of the growth or cells from it. Tubercular disease of the kidneys causes suppuration, and may be detected by finding the tubercle bacilli in the pus.

AN ARKANSAS METHOD OF TREATING SMALL-POX. — A simple and effective method of stopping the spread of small-pox was tried in a rural district of Arkansas last week. A negro being found ill with small-pox in his cabin, the neighbors set fire to the house and burned it all up — small-pox infection, cabin and negro.

APPENDICITIS: SOME IMPRESSIONS DERIVED FROM AN EXPERIENCE OF 44 CASES.¹

BY HOMER GAGE, A.M., M.D., WORCESTER, MASS.,
*Surgeon to the Worcester City Hospital, to the Memorial Hospital,
and to the House of Providence.*

OUR knowledge of the frequency and importance of inflammation of the vermiform appendix and its results dates back in this country to the paper of Fitz, read before the Association of American Physicians in 1886. From a purely pathological study, he demonstrated beyond all dispute, not that appendicitis was a new disease, but that it had always been the unrecognized cause of a great variety of acute abdominal diseases, hitherto classed as inflammation of the bowels, peritonitis, typhlitis and perityphlitis. His conclusions have been since then confirmed and strengthened by a constantly increasing surgical experience. Dr. M. H. Richardson, whose 281 cases lately reported represent one of the largest individual experiences, expresses the opinion that at least 90 per cent. of all cases of acute peritonitis occurring in young adults originate in an inflamed appendix, an estimate which is, I think, not likely to be diminished by further investigation. Dr. Richardson further expresses his firm conviction that "excluding certain zymotic diseases, it is the cause of more deaths than any other acute abdominal lesion." No surgical subject has within recent years attracted so much attention or given rise to so much discussion. Its frequency and importance have been strenuously urged on all sides, and very large and constantly increasing personal experiences have been reported. It is confined to no localities, to no conditions of life. The picture it presents is being recognized by the profession everywhere as an old acquaintance under a new name.

In spite of all the discussion, and the large experience so rapidly acquired, the problems created by the newly discovered pathology are by no means finally solved. No one can lay down any rules by which we can be governed in diagnosis, prognosis or treatment. We must, for a time at any rate, be content to be observers only. He who studies and observes much, finds his opinions changing so often that he is very reluctant to attempt the instruction of others. One opinion alone I find not changed but strengthened from the beginning, that is, as to the gravity and danger that exists in every case, no matter how mild it may appear to be. This one fact I would impress upon you; for the rest, I have preferred to give you briefly some impressions as they have been made upon my mind by the study of these 44 cases, asking you to remember that I regard them as impressions only, which are still subject to change, but from which further study and experience will, I hope, evolve more definite conclusions.

In the 14 cases in which the appendix was removed, a fecal concretion has been found three times, twice in the appendix itself, once in the bottom of the abscess cavity. I have never found any other foreign body present. In three cases, traumatism was the alleged cause, and in one the attack followed the ingestion of large quantities of grapes. In a very few instances, the attack was preceded by diarrhoea, with

¹ An address delivered before the Thurber Medical Association at Millford, Mass., February 22, 1894.

acute digestive disturbance; but for the great majority of all cases—I should say at least 75 per cent.—no cause could be assigned. I do not believe that the preponderance of males, in my own series 35 out of 44, can be fairly interpreted to indicate hard labor or exposure to injury as a predisposing cause. My own feeling is that the cause is usually to be found in the accidental retention in the appendix of larger or smaller fecal masses, and that their effect is determined by the kind and virulence of the bacteria present with them. Another determining factor is probably to be found in the congenital or acquired variations in the length, position and patency of the appendix. These variations are of still more importance from their effects upon the clinical history and symptoms of appendicitis.

The appendix is ordinarily from two to four inches in length, although considerable variations in both directions have been occasionally noted. Its base is fixed near the ileocecal valve, at the junction of the longitudinal striæ of the colon, and is therefore subject only to such changes in position as affect the cæcum as well. From this point, however, the appendix and its mesentery may lie in almost any direction, extending downward into the pelvis, transversely across the abdomen, with its tips reaching beyond the median line, or upwards on either side of or even behind the ascending colon. Its position, of course, fixes the location of pain and tenderness, which may, therefore, be found almost anywhere within the abdominal cavity. Many cases of appendicitis are thus the more readily mistaken for cases of peritonitis of idiopathic or unknown origin, a diagnosis that occasionally seems to be verified by a fruitless search for the appendix at the time of operation. Allow me to cite one example from my own experience.

E. E., grocer, thirty-five years old, patient of Dr. George F. Woodbury, was seen December 18, 1891. He had a history of a previous attack in August, 1891, since which time he had constantly complained of pain, chiefly epigastric, for which he sought counsel in Boston. Present attack came on suddenly in the night, and on account of absence of local signs, I advised delay, until on the 20th it was clear that a general peritonitis was impending. At the operation, peritoneum was everywhere injected and there were some fibrinous adhesions, but no pus and no appendix could be found. The patient died two days later; and at the autopsy, the appendix was found lying behind the cæcum and extending upwards about four inches, its tip resting on the right kidney. Its end was perforated, and pus could be squeezed out of its entire length, and had already formed a small abscess between the colon and the kidney.

Here was an appendix which had given rise to pain chiefly in the epigastrium, and which from its concealed position had almost escaped detection, and could not have been removed. I believe that the most favorable position for finding the appendix is when adherent to the iliac fascia or along the outer side of the colon. From these places it can almost always be removed, because the general peritoneal cavity can be more easily and more perfectly protected, and because the dissection can be prosecuted with a greater sense of security; one has a better view of the field of operation, and there is less danger of injuring important structures.

Dr. Richardson has lately raised the question as to

whether or not the appendix is always perforated, and expresses his "strong conviction that in all severe cases, and, in fact in all cases where there is a localized peritonitis there is a larger or smaller perforation with extravasation." Without wishing in the least degree to question this statement, it seems to me that there must be a few exceptions. I have twice removed appendices in which no perforation could be discovered by the naked eye or by the probe. (Both specimens are shown here.) The first is from a man who had had three previous attacks, and whom I operated upon forty-eight hours after the beginning of the fourth. Upon separating an adherent mass on the inner side of the colon, I succeeded in isolating the appendix, which was very much thickened, its surface red and slightly injected. There was no pus. Immediate improvement followed its removal. The second is from a young man who had been sick five days, complaining chiefly of pain in the right iliac region. The appendix was found non-adherent, somewhat thickened, with a bulbous tip, which was directed forward against the abdominal wall, and corresponded with the point of maximum tenderness. Microscopical examination of its contents showed that it contained a fecal concretion with a small amount of pus. In both of these cases, the inflammatory process, which always begins from within, in the mucus membrane, had extended outward, involving successively all the coats of the appendix and ultimately would have perforated it, perhaps. Neither perforation nor extravasation had, however, taken place up to the time of my interference. The first was certainly one of the severest and most threatening of my cases, and the second was rather a late operation.

The most important pathological factor is, I think, the limitation of the process by protective adhesions. They may be formed by the adherence of adjacent coils of intestine, by the envelopment of the appendix in a fold of omentum, or by its adherence to the iliac fascia, or along the outer side of the colon, as before mentioned. At any rate, the result is a localized abscess, which may or may not be adherent to the abdominal wall. Should extravasation take place before the formation of adhesions, a general infection follows, and the case cannot be distinguished from what has always been called idiopathic general peritonitis.

The typical case of appendicitis presents a picture so familiar to us all as to require but little attention. A child or young adult suddenly seized with abdominal pain and vomiting, the pain at first general, then more marked in the right iliac region, accompanied by tenderness, and in the course of time by the development of a bunch. This is the type, from which, however, there may be wide variations. The onset is almost always sudden. Chills or chilly sensations may be present, but are just as often wanting, even when suppuration has taken place. Vomiting is often, though not necessarily, an early symptom, and when present usually ceases with the localization of the inflammatory process. Its continuance, especially if changing to simple regurgitation, is always ominous. I have, however, recently had two cases in which, after the removal of the appendix and drainage of the abscess, vomiting of a thin, dark-green fluid persisted for several days, both patients ultimately recovering.

The pain is at first general and then local. It may be very severe, or quite moderate, in cases which at operation present very similar conditions. Its loca-

tion is, I think, of but little value, because the position of the appendix varies within such wide limits. Absence of localization is important as indicating a more general infection of the peritoneal cavity. Tenderness, like pain, may be general or local, and in any part of the abdomen. With the appendix in its ordinary place, the point of maximum tenderness is, as indicated by McBurney, usually to be found midway between the anterior superior spine and the umbilicus. The exceptions to this are, however, nearly as many as the observances, and I think McBurney's point as a diagnostic sign should be altogether discarded.

Dulness, when present, helps to the localization of the inflammation, but its absence is entirely without significance. Its value in any case is extremely limited. Abdominal distention, especially if general, is, I believe, one of the most dangerous symptoms. Fortunately, it is not an early one, and can generally be anticipated by operation. Its presence not only indicates a more or less general peritoneal infection, but also offers a serious obstacle to the mechanical part of the operation. The effect of its full development I shall refer to again.

Temperature I have come to regard as of but little value in indicating the nature or severity of the attack. I have operated in the face of a normal temperature for two days, and found a foul abscess with double perforation of the appendix, and, on the contrary, with a temperature of 103° , have found no pus, and simply an inflammatory thickening of the appendix. It is certainly a much less reliable guide than the pulse, and I am inclined to agree with Elliot that many of the most serious cases have a normal or nearly normal temperature.

One of the most interesting problems in connection with the clinical history of these cases is their tendency to recur. How great that tendency is cannot yet be accurately stated. Fitz found it in 11 per cent. of 257 cases. Out of the 44 cases which furnish the basis of my paper, 12 gave a definite history of two or more attacks. It is safe to say that in the very large proportion of cases the first attack is the last, but that after one or more recurrences others may be pretty certainly expected; and one thing is, I think, pretty definitely settled, namely, that one can never tell how severe the next attack may prove. A patient who has had one or more recurrences is in constant danger of an attack so severe as to be beyond surgical help from the outset.

One word about the differential diagnosis: it is not always easy to distinguish appendicitis from other acute abdominal affections. When the local symptoms are not clear, internal strangulation, twists and intussusception, with other forms of intestinal obstruction, must be carefully considered, and the operator must, of course, be prepared for any one of them. Dr. Richardson reports two cases of strangulation in omphalo-mesenteric remains which were mistaken for appendicitis. In one case of suspected appendicitis which I saw with Dr. W. E. Paul, then of Southbridge, and which he has lately published in the *Boston Medical and Surgical Journal*, operation was deemed inadvisable because the patient was already moribund. Autopsy revealed a hæmorrhagic pancreatitis as the cause of death. Many of these conditions can be eliminated only by exploratory incision, bearing in mind always that in healthy young adults, especially males, a sudden attack of acute abdominal pain,

with attendant symptoms pointing to the development of a local or general peritonitis, means in the great majority of cases an inflamed appendix.

In considering the management of these cases, let me say a word first about medical treatment, especially treatment by salines, so strenuously urged by Dr. Gordon, of Portland. Since the revival of saline treatment of peritonitis by Tait, we have all seen at times in appropriate cases most satisfactory results. The theory of its benefit, as suggested by all of its admirers, as well as by Gordon, lies in its depletive effect, not only upon the general, but also upon the portal circulation; the free watery dejections at the very beginning of the trouble are believed to cause the absorption of exudates before they have a chance to undergo decomposition, and also to subdue inflammation by their local depletion of the blood-vessels. The advantages of this method are obvious if its safety can be demonstrated. The dangers are from the breaking down of protective adhesions by increased peristalsis, and from favoring the extravasation of the intestinal contents through the perforated appendix. The first objection is, perhaps, somewhat theoretical; but the delicacy of the adhesions, and the ease with which they are ruptured during most careful manipulations, are familiar to all who have seen early operations. I have seen one case in which the adhesions which separated a localized abscess in a child were ruptured during sleep, and another in which in a young adult the rupture took place during an effort at stool; in both cases the disappearance of the local swelling was accompanied by collapse, rapidly progressing general peritonitis and death. In the second case, the abdomen was opened ten hours after the accident, a large quantity of pus lying free in the abdominal cavity evacuated, but too late to be of any service. This danger is not only theoretical, but real and very much to be feared. That salines may promote further extravasation of intestinal contents through the perforated appendix is denied by Dr. Gordon, on the ground that at the onset of the attack communication is shut off between the cæcum and appendix by closure of the natural opening. His statement is unsupported by any anatomical demonstration, and is contradicted by the published records of almost all the leading authorities upon this subject. At the recent meeting of the Surgical Section of the Suffolk District for the consideration of this subject, Drs. Richardson, Beach, Cabot and Elliot all testified to finding fæcal matter in peri-appendicular abscesses and in the appendix itself, and at least two of them testified to having seen gas and intestinal contents escape from the perforation at the time of operation. I have myself found fæcal matter in the appendix, and have twice after ligation and removal of the appendix, where there was no possibility of cæcal perforation, had fæcal matter discharged through the drainage-tube on the first two or three days, and not thereafter. I believe it can be accounted for only on the ground of direct communication between the cæcum and appendix. In spite of its advantage, therefore, I believe the indiscriminate administration of salines in appendicitis is attended with the gravest danger. I have once or twice resorted to salines, or, preferably, other laxatives, but only in the most guarded way, and in cases where I felt reasonably sure that perforation had not taken place.

For the mildest cases, and where for any reason

temporizing has seemed best, I believe the old-fashioned treatment by rest, opiates and hot applications to be the safest. The so-called simple catarrhal inflammation without perforation will improve as quickly and as surely under this as under the more active methods, the only danger is in concealment of graver symptoms which might demand interference by the opiates, and this has the advantage of being entirely within our control.

It is as impossible with our present knowledge to determine what proportion of cases will recover under such palliative measures as I have just described, as it is to lay down any rules for surgical interference. We do know that while a very considerable proportion of cases recover perfectly and permanently without the necessity of interference, an equally large number, beginning in precisely the same way, quickly develop most dangerous symptoms, which demand at once prompt incision and exploration. Until we discover some way to distinguish at the outset between these two classes, it is natural that those whose experience has been more largely with the severe type should prefer and advocate immediate operation as soon as the diagnosis is established. It is argued that the danger from an operation at such a time is extremely small and that the conditions have not yet been complicated by the presence of large exudations and by strong adhesions, so that they are more easily recognized and more securely dealt with. The argument has much to commend it, and I think there can be no question that the trend even of the most conservative surgical opinion is towards a more rather than a less radical procedure. We are, however, but in the infancy of our knowledge of this subject, and I feel hopeful that we may some time be able to draw at least a sharper line between those cases whose natural tendency is to recovery and those which are destined to progress. There is at best some risk of disseminating an inflammation which nature has attempted to localize, and much danger of weakening the abdominal wall, a very serious consideration, especially to the laboring class. I have not therefore, as yet, been convinced that operation is always to be advised at the very beginning of the attack, and yet in some cases I should propose it unhesitatingly, especially in those where a general peritonitis seemed imminent.

I wish I might be able to give you the exact reasons which govern me in forming such a conclusion, but I cannot. Impressions, even if founded on experience, which cannot be formulated into words, are, I know, most unscientific and unsatisfactory, perhaps, often unsafe guides; but they exist, and I cannot yet at all accurately describe them.

Whenever vomiting continues and is accompanied by any suspicion of increasing distention after the first twenty-four hours, I am sure that interference cannot be proposed too quickly. It generally indicates a greater or less tendency to general peritoneal infection, and its persistence is a symptom of very grave import. The more nearly does it approach a condition of regurgitation, the graver does it become. In these cases, operation must be done in the very beginning, to be of any value. Patients who are regurgitating a dark-greenish fluid, even if not stercoraceous, and whose abdomens are much distended, are the worst possible subjects for operation. I have operated now four times under such conditions, and always with fatal result. Whenever general peritonitis is threatened, operation

must be done within the first twenty-four or forty-eight hours, and even then may be too late to avert death. After full development, operation is, I believe, counter-indicated, and the chance of a favorable result lies in the use of salines or other purgatives, with opiates enough to secure quiet. These are the cases in which the rectal tube, turpentine, enemata and other means for the relief of distention are indicated. In all cases of acute appendicitis, with or without localized symptoms, where a general peritoneal infection is feared or its beginning suspected, the time to consider surgical interference is, I believe, at the very outset. It is then that any delay is most dangerous. When fully developed, it is, I believe, almost always too late. The shock of ether, and the increased manipulation made necessary by distention of the intestine is almost always fatal, and if left to nature, such cases may occasionally recover. I have recently twice had that fortunate experience.

When after the first onset the symptoms become definitely localized with the formation of a tumor, and with a definite sense of local resistance and tenderness, delay may be less dangerous, and the appropriate time for interference is always more difficult to determine. Should the local conditions decidedly improve on the second day, it is, I think, fair to infer that nature will effect a complete restoration, or that she has, at least, succeeded in setting up a temporary barrier to the extension of the inflammation. I believe that there are many cases in which the improvement in physical signs, as well as in constitutional symptoms, is so rapid and so decided that interference, if proposed at all, is to be considered only as a safeguard against possible recurrence. In the great majority of these cases of acute appendicitis, where the process is distinctly localized, I believe the most favorable time for interference is as early as the third day. The risk of delay seems to me much greater than the danger of early operation. The second and third days eliminate the mildest cases; the others may assume a far more dangerous aspect with little or no warning. Even as early as this a gangrenous condition of the appendix may be found, around which an abscess has already been formed. This has been the condition in three of my cases.

The first, N. C., male, seventeen years old, was seen in consultation with Dr. J. O. Marble, of Worcester, on the 30th of January, 1893. The attack began with severe abdominal pain and vomiting on the 28th, and I operated sixty-four hours later, that is, on the third day. His pulse was 120, temperature 102°, and his general aspect was exceedingly bad, though he professed to feel better. Upon opening the abdomen, I came at once upon a mass of gangrenous omentum, the meshes of which were infiltrated with pus. Just beneath this was an abscess cavity, containing about four ounces of very foul pus, lying in which was the appendix, perforated about two inches from the cæcum and gangrenous about the perforation. (Specimen shown.)

Again on May 3d, I operated on Mrs. M., twenty-seven years old, a patient of Dr. F. G. Fay, of Worcester, who had been suddenly seized with acute abdominal pain on the evening of the 30th of April; the operation was, therefore, on the third day. The general peritoneal cavity was opened and a mass of adherent coils of intestine found in the cæcal region, not adherent to abdominal wall. On separating the adhe-

sions, about two ounces of pus was evacuated, and the appendix found perforated and gangrenous. (Specimen shown.)

On October 3d, I operated upon A. W., male, twenty-one years old, who was referred to me by Dr. Leonard White, of Uxbridge. His attack began suddenly on the morning of the 20th. Incision revealed pus just below the cæcum, with a much thickened appendix, so adherent that it was torn across at the point of perforation, and only about one inch was removed. The rest was ligated and left.

These three cases illustrate the severe conditions which may be found as early as the third day, even when the inflammatory process has been definitely limited by adhesions. I believe all would have been more difficult to manage, and more dangerous to the patient had there been even twenty-four hours longer delay. As it was, all recovered.

The most serious objection to early operation is the danger of breaking down adhesions, and defeating nature's attempt to localize the peritoneal infection. Larger experience and greater familiarity with the conditions to be found must diminish very much the force of this objection. It is also, I think, far outweighed by the greater facility in operating, the greater ability of the patient to withstand shock in the early stages, and by the increased chance of doing a thorough and complete operation. I am one of those who believe that the operation is every way more satisfactory when completed by the removal of the appendix, and that whenever possible this ought to be done. I am sure that when it can be done without too great violence to the adhesions, convalescence is established more quickly, is less liable to interruption and recovery is much more certain to be permanent and complete. I have accomplished it now in 14 cases, with 13 recoveries. The only death was in the first case in which I removed it. I would not, by any means, convey the impression that its removal should always be attempted. In the ordinary late operation, it cannot often be found, and even when found, its removal is usually impossible, so tough and firm are the adhesions in which it is imbedded. It is to be undertaken only in early operations, when the adhesions are light and easily separated, and when the general peritoneal cavity can be fully protected. In cases thus properly selected, the removal of the appendix makes a more finished operation, adding very little if any to the immediate danger, and adding much to the rapidity and permanency of the recovery.

So, also, with regard to the omentum, when it is found wrapped about the appendix or involved in the mass of adhesions, if it is gangrenous, or infiltrated with pus, or engorged with extravasated blood, so that it looks like a piece of liver, I would always ligate and remove it. I have done it for all of these conditions, without in any way complicating the operation, and I think it removes a source of considerable danger.

I have not spoken of the operation between the attacks, because my own experience has been entirely with acute appendicitis. In recurrent cases, I believe most heartily in operating during the interval of quiescence, but I have had no experience of my own. In two operations done during exacerbation, in cases of recurrent or chronic appendicitis, I have, however, seen conditions which I have found nowhere described and which seem to me exceedingly interesting.

This first was in a boy thirteen years old, who in

the preceding four months had had several attacks of appendicitis with very short intermissions, and who for a month past had had a small hard tumor, very tender, in the right iliac region. Each attack would begin with pain in the region of the tumor, vomiting, and a temperature rising to 101° or 102°. With rest in bed, counter-irritation and careful attention to diet, each attack would quickly subside, but the bunch had remained. I saw the boy during one of these exacerbations, regarded the case as one of localized abscess, and, as he was a near relative of mine, I asked Dr. M. H. Richardson, of Boston, to perform the operation. He, too, was convinced of the presence of pus, but incision revealed a hard mass of firm, tough adhesions, which were separated so as to expose the cæcum, but no pus and no appendix were found. The cavity was packed with gauze, and healed without suppuration, the boy regained his former health and strength, the bunch entirely disappeared, and there has been no recurrence during fifteen months that have passed. In October last I had an almost precisely similar experience in a Swede twenty-seven years old, who had symptoms off and on for eight weeks, with a well-defined tumor for at least a month. I operated in the midst of an exacerbation, found no pus, and only a hard mass of inflammatory exudation, imbedded in which was the cæcum. So firm were the adhesions that I did not dare attempt their further separation to search for the appendix. The man made a good recovery and has remained well.

These cases illustrate the difficulties that may be met with in what promise to be the simplest operations, and they are especially interesting to me, because I cannot understand the conditions which have caused them, nor the apparently beneficial effect of exposing and disturbing them.

With regard to the results in cases of appendicitis, very little can, I think, be learned from any one individual experience; and until we have some accurate method of classification, we can learn little from the study of compiled statistics. Of my own cases there were 12 not operated upon, 5 of whom died; 4 were in a condition which seemed to me to render operation useless, and the 5th died from internal rupture of the abscess. One of the cases that recovered, died three months later from a recurrent attack. In the 32 operations, there were 25 recoveries and 7 deaths. Of the latter, five were from the continuance of general peritonitis which was present at the time of operation, one was from pyæmia in a late operation upon a large localized abscess, and one was after an operation done for rupture of an abscess into the general peritoneal cavity.

In the 25 cases that have recovered, I have as yet had no rupture through the cicatrix of the wound. I believe, however, that this is only because sufficient time has not yet elapsed; that hernia will come in some at least, I feel perfectly sure. It must come, especially in those cases where drainage has been used. It is less likely to occur in the early operations where drainage can be dispensed with, but even then it cannot be wholly avoided. Some firm support ought always to be worn for years after the operation, and the thought that we are thus permanently weakening the abdominal wall, and imposing upon a man a great inconvenience if not positive danger, ought to make us exceedingly careful to avoid unnecessary interference.

Fæcal fistula is another occasional sequel of opera-

ion. I have had one fistula that persisted for seven months after the operation, but has finally closed spontaneously. It was in a case of late operation, where the appendix could not be removed, and the abscess was simply opened and drained. It is a great annoyance to the patient and to the physician, but will almost surely heal of itself, and rarely requires operative interference.

In conclusion, allow me to repeat that we can draw no hard and fast distinction between those cases which will require operation and those which will not. I feel in almost as much doubt as ever each time that the question is presented to me. There are one or two points, however, that increasing experience has impressed more and more strongly upon me, and they are the only definite conclusions which I can present. They are: (1) appendicitis is one of the most important as well as one of the most dangerous of all acute abdominal affections; (2) that some cases are fatal from the very nature of the initial attack; (3) that some have a natural tendency to recover; but (4) finally, that the great majority can be relieved only by surgical interference, and that early operations are in every way less difficult and less dangerous than late ones. In the majority of cases, the presumption is in favor of early operation, and unless distinctly counter-indicated the earlier the better. A surgeon seldom regrets an early operation, but is often disappointed by delay.

PRIMARY NASAL DIPHTHERIA.¹

BY CHARLES W. TOWNSEND, M.D.

THAT nasal diphtheria is a severe and often fatal disease, and that it is almost always secondary to diphtheria in the throat, is the generally-received idea both from practice and text-books.

Thus Dillon Brown, in Starr's "Text-Book of Children's Diseases," just published, says: "In the nares diphtheria is very serious, on account of the abundant lymph and blood-supply," etc.

W. Gilman Thompson, in Pepper's "American Text-Book of the Theory and Practice of Medicine," also just published, says: "Cases of nasal diphtheria are apt to end fatally unless vigorously treated."

And J. Lewis Smith says, in Keating's "Cyclopædia of Children's Diseases": "Nasal diphtheria involves great danger, from the fact that it is likely to give rise to systemic infection of a grave type." Lower down he says: "Although commonly diphtheritic inflammation of the nasal surfaces is secondary to that of the fauces, it is sometimes the primary inflammation. It may exist for some days before the fauces become affected, and under such circumstances the diagnosis is frequently not made until the disease is in an advanced stage and profound blood-poisoning has occurred."

That mild primary cases sometimes occur, the mildness of whose symptoms may permit them to go unrecognized, is a point I wish to emphasize, and particularly the fact that these cases are of great danger to the public health.

Dr. A. L. Mason² refers to these cases when he says: "Primary nasal diphtheria is probably more

common than is supposed, and a not infrequent source of unsuspected danger." Jacobi also alludes to them; and Major³ reports five cases very similar to those I am about to relate. The latter says of nasal diphtheria: "When of a *primary* nature, it is very likely to be overlooked altogether." It seems probable that some cases formerly supposed to be membranous rhinitis were in reality nasal diphtheria.

During the months of November, December and January of this winter fourteen cases of diphtheria occurred among the patients of the Children's Hospital, all but two of which came under my charge in the isolating wards.

The bacteriological examinations were made for the hospital by Dr. J. H. McCollom at the Harvard Medical School, and, it is unnecessary to say, were of the greatest value.

There were seven cases where the nose was affected; in six cases the disease was limited to the pharynx; and in one case an old tracheotomy wound was attacked, the disease spreading to the bronchi and rapidly proving fatal.

The six pharyngeal cases I will pass over briefly. They illustrate the well-known difficulty and oftentimes the impossibility of making a diagnosis of diphtheria from gross appearances or symptoms. They were all mild cases; all recovered. One of the earlier cases began with coryza, and had a nose-bleed on the day preceding the beginning of the throat affection; and although there is no positive proof of nasal diphtheria from the absence of cultures from the nose in this case, it is extremely probable, in view of the other cases, that this one was originally nasal diphtheria, and as such was overlooked.

Of the seven nasal cases of diphtheria, in five the disease was primarily nasal, being confined to the nares alone in four, in one extending later to the pharynx and larynx, while in the remaining two cases the disease was at first pharyngeal, and later involved the nose. These last two cases represent the secondary nasal forms more commonly seen, partly from the fact that the diagnosis of the trouble in the throat having been made, it is natural to suspect an extension to the nose in case there is a nasal discharge, and to look for membrane there, and partly because secondary nasal diphtheria is usually a very severe disease.

The primary nasal cases are easily overlooked; the diagnosis frequently cannot be made without a bacteriological examination, and they are particularly dangerous as sources of infection from these causes, and from the fact that the bacilli may be retained for a long time on the voluminous mucous membrane of the nose after the patient has apparently recovered, and may even at times elude the search of the bacteriologist, as some of my cases show.

CASE I. A boy, four years old, began to have a nasal discharge on January 3d. This increased on the following day, but there was no rise of temperature, and the pulse showed no weakness. The nasal discharge was watery and at times muco-purulent, and was not offensive. On the third day of the coryza careful examination showed some gray membrane in each nostril, and a bacteriological examination demonstrated the Klebs-Löffler bacillus. There were nose-bleeds from time to time. The temperature, as will be seen by the chart, remained between 99° and 100°

² Diphtheria and Scarlet Fever at the Boston City Hospital. Bulletin 4, Harvard Medical School Association.

¹ Read before the Boston Society for Medical Improvement, March 12, 1894.

³ Burnett: System of Diseases of the Ear, Nose and Throat, vol. 1, p. 370.

until the twelfth day of the disease, going once to 101°, the child feeling meanwhile well enough to be up. Examinations by cultures taken from the nose

CASE I.

by the platinum wire were made from time to time, and the Klebs-Löffler bacilli were still found on the thirteenth day, or three days after the temperature had dropped. On the fifteenth day, the day following the cessation of nasal discharge, a culture was taken and no bacilli found.

The child was not allowed to go home until six days later, or a week after the cessation of the nasal discharge, but the sequel shows he still retained some of the Klebs-Löffler bacilli in his nose. Shortly after returning home, a servant, who had not been away for

ure was at once taken from his nose, and the Klebs-Löffler bacilli were found. On the following day a little membrane was visible, and there was a watery discharge from the nose. On the third day there was apparently nothing the matter with him but a bad coryza. No more membrane was seen, and the temperature came to normal on the fifth day. On this day the Klebs-Löffler bacilli could not be found. No subsequent cultures were taken, but it is probable that the bacilli would have been found for some time in his nose.

CASE III. A girl, seven years old, again illustrates the purely nasal forms. During the first week a thick, glistening, gray membrane was plainly visible in the nose, and the patient suffered from nose-bleed twice. The Klebs-Löffler bacilli were found until the fourteenth day of the disease, on which day the membrane disappeared from sight. As will be seen by the chart, the temperature continued between 99° and 100° for twelve days after the disappearance of the membrane. She was not discharged from the hospital until all signs of nasal disease had disappeared and the last bacteriological examination was negative.

Two or three days after her return home her mother was taken sick with diphtheria, recovered, but died suddenly a week later with, as far as could be learned, suppression of urine.

CASE IV. Girl, two and a half years old, began with a cold in the nose, and at the same time some white circumscribed pin-head spots appeared on the tonsils, but entirely disappeared within forty-eight hours. The diphtheritic bacilli were found in these apparently follicular spots, as well as in the nose. Membrane then appeared in the nose, and there was

CASE III.

over three weeks, came down with diphtheria. That the child's nose was the probable source of infection was proved by the fact that the specific bacilli were discovered there when he presented himself at the clinic four weeks after his discharge from the hospital, and over five weeks since his apparent recovery. At this late date, however, a nasal discharge was present, having started up after leaving the hospital.

CASE II. A boy, four years old, was the mildest case of all. He was kept isolated in the main hospital, not coming under my charge; and I am indebted to the courtesy of Dr. Bradford for permission to include it with the others. The child began with coryza and nose-bleed and a temperature of 101.8°. A cult-

some sanguino-purulent discharge for a day or two. After this the discharge was slight and muco-purulent or watery, coming and going like an ordinary coryza. At no time after the first three days could one have made from the gross appearances any other diagnosis than a coryza, as there was no membrane to be seen. Except on one occasion, the Klebs-Löffler bacilli were, however, found at every examination, which was on alternate days, until the twenty-sixth day of the disease, and there was some muco-purulent discharge at intervals until the twenty-third day. The temperature, as will be seen by the chart, started off at first as if in correspondence with the apparent follicular tonsillitis, and then ranged from the third to the

fourteenth day between 99° and 100°, remaining normal after the fifteenth day.

The pulse showed but little evidence of weakness,

CASE IV.

except of an occasional slight nasal obstruction, the child appeared perfectly well after the first four days, and at home would have been, if the diphtheria were unrecognized, an active spreader of the disease.

For the sceptical, as to the value of the bacteriological method of diagnosis, the following case is of interest, for its later violent course confirmed very fully the early bacteriological diagnosis. This was the only primary nasal case in which there occurred an extension of the membrane from the nose.

CASE V. A boy, six years old, said his nose was

An examination of his temperature chart is interesting. The child was in the hospital for a stiff knee, and there was no active process going on there to cause an elevation of temperature. It will be seen that for a week before the first temporary nasal discharge occurred the temperature was elevated about 100°. This is certainly suggestive of a beginning of the nasal diphtheria at this time. Another interesting point is the normal and subnormal temperature for three days following the appearance of the membrane in the nose and the discovery of the specific bacilli.

The continued slight elevation of temperature between 99° and 100° seen in several cases when the disease is confined to the nose is interesting. In the following case this continued for a month after the membrane had disappeared from the portion of the nostrils easily visible. With this temperature in bed, the patients seemed to feel perfectly well. If they had been about, they would very likely have shown evidences of debility by feeling tired and irritable. The early history of this case is very suggestive as regards the "follicular tonsillitis."

CASE VI. Boy, six years old, had an attack of what appeared to be follicular tonsillitis on October 15th, lasting five days. No bacilli could be found. On November 2d he again complained of sore throat; his tonsils were swollen and covered with white spots. Again no bacilli could be found. A failure to carry the wire to the bottom of the crypts may have accounted for this, and it is possible that these were in reality mild attacks of diphtheria. On November 20th began a third attack, apparently similar to the others, but the Klebs-Löffler bacilli were found. This time the spots coalesced, spread to the uvula, and pre-

CASE V.

sore on January 12th. There was a slight discharge at this time, which dried up in a day or two, and nothing was thought of it. Seven days later he had a nose-bleed, and on the following day glistening white membrane was discovered in one nostril, and a nasal discharge began. An examination on this day showed the Klebs-Löffler bacilli. Two days after the membrane appeared it spread to both nostrils, and again two days later both tonsils and the posterior wall of the pharynx were rapidly covered with the membrane. Again, two days later, evidence of laryngeal infection was shown by the croupy cough; and although intubation was performed by Dr. Goldthwait, the patient died on the following day.

sented the clinical appearance of diphtheria. A week later the membrane was seen in the nose; but it disappeared from there on December 7th, and from the throat on December 16th. A slight nasal discharge continued at intervals, and the bacilli continued to be found in the nose for a month after the membrane ceased to be visible. The temperature ranged from 100° to 102° for the first three weeks of the disease, and from 99° to 100° during the last three weeks, during which time no membrane was visible.

The child was discharged from the hospital apparently well over a month after membrane had disappeared from sight, and nearly a week after a bacteriological examination failed to find the Klebs-Löffler

bacilli. The terrible bacilli were still concealed in his nose, however, and would undoubtedly have been discovered if he had been retained longer in the hospital and more examinations had been made. The lapse of a month since the disappearance of the membrane, his apparently complete recovery, as well as the fact that the last bacteriological culture was negative, served to justify his discharge. He was given an antiseptic bath and a complete change of clothing.

Eight days after his return home to a neighboring town the child's sister developed a violent case of diphtheria, the membrane spreading to the nose, roof of the mouth, pharynx and larynx, and proving fatal on the tenth day. The mother and older sister also contracted diphtheria and recovered. There had been no cases of diphtheria reported in the town for two months before this, and but one since. The parents had not visited the diphtheria wards at the hospital for five weeks before the little girl's sickness.

It would seem as if the boy from whom these cases spread had acquired an immunity from the effects of the disease by the length of time in which he harbored the bacilli. That the virus had not become attenuated by its long stay in this individual was proved by the virulence of its action in the fatal case.

CASE VII was of the usual type of secondary nasal diphtheria. The patient was already very sick with surgical sepsis, which obscured the symptoms of diphtheria. The case proved fatal.⁴

All but one of the nasal cases had nose-bleed, slight or severe, at some time in the course of the disease, often when no membrane was visible. Only two of the others had nose-bleed, and in one of them, as I have already remarked, nasal diphtheria is strongly to be suspected. A swelling of the cervical glands in these cases was not noticed.

The source of these cases of diphtheria it is not difficult to trace, as there had been free intercourse between the patients at different times. The habit of picking the nose, so common among children, must furnish an easy method of infection.

By way of summary, the following points seem to me to be of interest:

(1) The fact that primary nasal diphtheria may occur of a very mild type.

(2) The dangerous character of these cases, as they are likely to go unrecognized for the following reasons:

(a) The resemblance of these cases to ordinary coryzas, a membrane not being noticed in some cases except by careful scrutiny.

(b) The normal or only slightly elevated temperature often present, with but little constitutional disturbance.

(c) The intermittent character of the nasal discharge, absent for several days, and then starting up again.

(d) The apparent recovery, even with cessation of nasal discharge, while Klebs-Löffler bacilli are still present.

(e) The fact that these bacilli have not lost their virulence; or, in other words, the fact that the patient having the bacilli in his nose, although apparently well, may transmit the disease in a fatal form to others.

(f) The difficulty of always finding the bacilli in the nose, even when they are present.

⁴ Since going off duty on February 1st five cases of diphtheria have occurred at the hospital, four being of the mild nasal type.

(3) The importance of bacteriological examinations in all suspicious cases of nasal discharge.

(4) The importance of prolonged isolation, together with a refusal to consider a case cured until several consecutive negative cultures have been obtained.

A CASE OF AMOEBIC DYSENTERY.¹

BY C. F. WITHERINGTON, M.D., ROXBURY, MASS.

THE patient, Olaf Nilson, was a native of Norway, aged thirty-four years, unmarried. He gave his occupation as that of a longshoreman, and seems to have done various sorts of work about the wharves in several seaport cities of this country. When more distinctly maritime occupations failed, he had, among other things, tended bar.

For the six months prior to the middle of February he had been in the South, the first half of the time (or a little more) in Pensacola, the rest of it in Mobile. He had also worked for a while in one or both of these cities on previous occasions.

Up to two weeks before entrance to the hospital he avers that his health has always been perfect, except that he had measles in childhood and occasional headaches since. Yet, as he expressed himself, up to the present illness, nobody had ever been stronger and in better health than he. His mother died of dropsy, and a brother of the "falling sickness"; three sisters and two brothers are alive and well.

Coming, then, from Mobile to New York, he was suddenly taken about the time of his arrival with chills, which have recurred since. He thinks he has been feverish, and diarrhoea appeared coincidently with his first chill. At present he says he has about ten movements a day, which is not as many as he had at first. The stools have been dark-brown and bloody. He has lost weight rapidly. Pain is not complained of.

On his entrance to my service at the City Hospital, March 1st, I found him a man of large frame, a good deal emaciated, with a dusky face; temperature, 97.5°; pulse 116, fair quality. Examination of liver, heart and lungs was negative. There was slight abdominal tenderness. The splenic dulness began at the seventh rib, but the margin was not felt. He had the odor characteristic of chronic diarrhoea, and seemed a very sick man. The movements were ten to twelve in the twenty-four hours, and were not involuntary. The stools were fluid and smooth, about the consistency of thin cream, of a reddish-brown color, and of not an unusual odor. There was no mucus nor masses of bright red blood; and in these respects the stools did not present the appearance of the common type of dysenteric colitis.

A specimen was therefore sent to Dr. Councilman for examination for *amoeba coli*, and its discovery was at once made by him.

The patient was treated at first by a dose of oil, followed by starch and laudanum injections, and as soon as the presence of the amoeba was reported the laudanum enemata were replaced by rectal douches of quinine (gr. xvi in a pint of water). They were, however, retained but a short time, and no improvement was observed from their use. The patient failed steadily, and died in the night of March 3d, about

¹ Read before the Boston Society for Medical Improvement, March 12, 1894.

seventeen days from the beginning of his illness, if his history of the invasion is correct.

The temperature remained generally subnormal, only once reaching 99°; and the respirations gradually quickened toward the end.

Clinical Department.

SCARLATINA WITH PERSISTENT HIGH TEMPERATURE, ASSOCIATED WITH WILD DELIRIUM, FINALLY CONTROLLED BY GUAIACOL.

BY FRANK E. PECKHAM, M.D., PROVIDENCE, R. I.

THERE were four children in the family, none of them having had scarlet fever, and the manner of infection could not be learned in this case.

The eldest child, age seven years, came home from school one night feeling badly and complaining of nausea. The next day there was vomiting and complete loss of appetite. On the third day, there being no change for the better, I was called in the evening.

The child at that time was lying quietly in bed, and the nausea was not so troublesome. The skin was covered with a mild eruption of scarlet fever. Throat slightly reddened. Parents had not noticed the eruption before, so the time of its appearance is unknown. Treatment: aconite, warm-water sponge-baths, liquid diet.

Fifth Day.—At the morning visit the eruption was well marked all over the body. Child had been very restless and delirious all night. Tonsils enlarged and covered with grayish membrane. Temperature 105°. Treatment: cold-water sponge-baths, phenacetine (grs. iiii every three hours), tincture ferri chloride (gtts. v four times daily for local effect), peroxide-of-hydrogen (15 volume) spray for throat and nose.

At the evening visit the temperature was 106°. Child wildly delirious. Facial expression very bad. Treatment: tub-baths now ordered, beginning with warm water, and gradually cooler, until the water was just as cold as it came from the faucet, which in March is pretty cold. The first bath lowered the temperature to 104°. The child enjoyed this and subsequent baths very much. The eruption became more and more marked, until the whole surface of the skin seemed to be raised above its usual level in one reddened, scarlet mass. The temperature rose again soon, and the parents had a hard night of it keeping the patient in bed. Chloral was given in five-grain doses up to fifteen grains. The subsequent baths through the night made no impression on the temperature. It would be 105° immediately after removal from the tub.

The temperature was always taken in the axilla, being, of course, much higher in the mouth or rectum.

Sixth Day.—At the morning visit the temperature was 105.5°. Lips parched. Eyes sunken. Child looked badly. The throat was clean, but red, swollen and angry-looking. The child in her delirium was constantly tossing around, and had to be held all the time.

Baths were continued. Phenacetine increased to six grains every three hours. Chloral used per rectum through the day, but when evening came I found the temperature 106°, and child looking like death. It seemed impossible for her to live until morning.

At this visit I rubbed twenty-five drops of guaiacol into the skin over the abdomen, and in two hours the temperature had dropped to 104°. In the night fifteen drops more were rubbed in, and at the morning visit on the

Seventh day, the temperature was 103.8°. Child had been delirious all night, but not quite so wild—a very slight improvement, which let in a small ray of hope. During the day fifteen drops of guaiacol were to be rubbed in. Phenacetine omitted. The tub-baths were continued. The evening temperature was 103.8°.

Eighth Day.—Patient not yet rational, but more tractable. Throat looking a great deal better.

Ninth Day.—The evening temperature was 101°; and the child had had a little refreshing sleep and looked a great deal brighter. Guaiacol now discontinued.

Tenth Day.—Temperature up to 103°, due undoubtedly to the discontinuing of the guaiacol; but the patient is really rational, and can talk reasonably for the first time. Scales appeared to-day.

From this time the temperature gradually fell, until on the fifteenth day it reached 99°.

The tonsils now became troublesome. First an abscess developed in the left tonsil, with the swelling externally. This was opened by an external incision on the twenty-sixth day of the disease. Then an abscess formed in the right tonsil, which was opened on the inside on the forty-third day. After this there was no further trouble; and my last visit was on the forty-seventh day, when scaling had ceased. Patient was out-of-doors in the eighth week.

I report this case to show that guaiacol may be of great use in the acute febrile diseases. It has been tried in typhoid fever, and found to be rather dangerous on account of depressing the temperature too far and causing collapse.

In this case there was a very high temperature; and it seemed to me that the delirium was wholly due to that, and as soon as the temperature began to yield the delirium began to subside.

The fact that the temperature rose immediately after stopping the guaiacol would seem to prove that it was really due to the drug, and not a coincidence.

Another interesting point was that the cold tub-baths had so little influence upon the temperature. These baths were enjoyed immensely by the little patient, who would quiet down and paddle in the water even when the delirium was at its height.

The three children in the family who were not affected were sent away, and did not return until the house had been fumigated; and up to the present time they have been perfectly healthy.

Medical Progress.

REPORT ON MENTAL DISEASES.

BY HENRY R. STEDMAN, M.D., BOSTON.

(Concluded from No. 20, p. 495.)

CASE OF ANTIPYRINOMANIA.

CAPPELLETTI* reports the case of an hysterical girl of twenty-three, weak and nervous. Headache for two years, treated by antipyrin in small doses. Drug be-

* Rivista Sperimentale di frenatria, xlix, 100.

came necessary to her. The pain became incessant, and the drug lost its effect. The dose was increased to eight grammes a day. She grew worse; lost her appetite; had poor sleep; and the pain grew worse, with tinnitus. She became excited, irritable and anxious half an hour before the time for dose. Was agitated, walked about, sighed, etc., if not given it. Carried it in her pocket. Diarrhoea and convulsions ensued when attempt was made to stop it wholly. In the asylum the dose was cut down to two grammes, with sulphonal to relieve pain. She then had nausea, vomiting, anorexia, pallor, small pulse, and was much depressed. This lasted three days, and was not relieved by food and stimulants. She then became slightly excited, restless, loquacious and irritable. Given bromide of potash up to six grammes, and valerianate of quinine, but had bad symptoms set in whenever antipyrin was cut down, with weak pulse, mental depression and hallucinations, etc. Then inert powders were given, the antipyrin was wholly stopped, and caffeine and bromide of potash substituted; finally these were cut down; and she at last recovered. Slow and progressive diminution of symptoms. The symptoms from withdrawal were much like those from withdrawing morphine.

MENTAL CONFUSION.

Dr. Charpentier,¹⁰ under this title describes a mental state characterized by perturbation in the ideational sphere, consciousness, absence of delusion, and coexistence of inquietude. Often it cannot but be considered as an almost physiological state resultant on passage from slumber to wakefulness in all adynamic states or cerebral congestive conditions. It may appear at the onset of many psychoses as well as among chronic insanias and epileptics. In all cases, however, the concomitant psychic phenomena (hallucinations, amnesia, stupor, mutism) mark the picture of mental confusion. It may exist alone, and constitute by its duration, a true pathological state. It is a rapid, disordered progress of ideas before consciousness, preserved, but astonished and restless. The ideas are not erroneous but so varied and tumultuous in their course and so numerous that their numbers and disarray confounds the patient, who, incapable of directing his ideas although preserving his consciousness, falls into profound inquietude. Mental confusion has been styled obvolitation, torpor, hebetude, intellectual vertigo and ideational chorea. What renders the case difficult is the fact that the patient renders an exact account of it only when cured. Furthermore, they are apt to analyze the mental state they have experienced, and for the patient merely to describe this mental state does not suffice to reproduce it.

How can, therefore, mental confusion be determined in a patient who does not complain of it? Dr. Charpentier states that answers to simple *terae* questions (age, birthplace, colors) will indicate presence of attention but may appear incoherent because of rapid ideation. Usually the patients seem stupid. This is often the case with young female dyspeptics. Often mental confusion occurs in the morning after an insomnic night, a slumber too profound and prolonged or consecutive to excess. The patient appears lost; acts without will or without taking account of his acts. Mental confusion among the insane is found chiefly among the acute confusional lunatics or the convales-

cent; when it exists among these last they cannot be regarded as cured.

Diagnosis is only made after recovery. Mental confusion should be distinguished from temporal mental enfeeblement of intoxications or infections (in these last there is a parallel enfeeblement of consciousness or absence of inquietude); from stupor (mutism, loss of consciousness of surroundings) and from vertigo (loss of consciousness and from involuntary movements). Mental confusion of prolonged or frequently recurrent type has a bad prognosis. It occurs in parietic dementia, chronic persecutorial insanias and precocious dementia. It may be produced by suggestion, intimidation or surprise.

DIFFERENTIAL DIAGNOSIS BETWEEN LITIGIOUSNESS IN THE SANE AND INSANE.

Dr. Ludwig Horne,¹¹ after a careful review of the literature of the subject arrives at the following conclusions:

(1) An amnesia reveals nothing of importance in sane litigants; in the querulous paranoiacs a hereditary taint, peculiarities in childhood and after-life.

(2) The sane litigant shows no abnormal somnatic symptoms; in the paranoiacs, somatic symptoms are seldom absent.

(3) The motives in sane litigious people are pleasure in law suits, or the desire to obtain a final decision in a particular point of law; in the insane, the motive lies in an hereditary defect—an inability to submit to an unfavorable decision.

(4) Characteristics of litigiousness: (a) The sane litigant maps out his course of procedure; the paranoiac believes it impossible to lose his case, and does not plan beforehand. (b) The sane litigant will not go beyond a certain point, decided upon in the beginning; the paranoiac does not limit himself. (c) The sane litigant can end his trial at will; the paranoiac is drawn into new trials by his disease.

THE FUTURE OF ASYLUM SERVICE.

Under this head A. Campbell Clark,¹² Medical Superintendent of Glasgow District Asylum, Bothwell, Scotland, says:

"Where are the defects of the nursing staff and its work? A. The defects of our nursing staff are threefold: defects of (a) quantity, (b) quality, and (c) organization. B. The defects of nursing work are the natural results of the foregoing, but they are also due to (a) large wards, (b) lack of personal co-operation of superior officers, (c) the same monotonous grind from week to week. The present number of nurses for acute and curable cases is too small, the hours of duty are too long, and they are not officially attached to particular cases. The remedy is, a larger staff, give much longer leave, and you can have a larger per cent. of nurses on duty.

"As regards the question of quality, that we want more style and higher education is a delusion most disastrous for asylums. Placed in the balance against a bright, sunny temper and obliging disposition, mere education would be found wanting. Sunshine in our attendants is dependent upon sunshine in their surroundings. In a word, don't keep them so long in harness at a time, feed them well, groom them well, make them as healthy and happy as the nature of their work will allow.

¹¹ *Men. Med. Bloet*, No. 46, 1893.

¹² *American Journal of Insanity*, January, 1894.

¹⁰ *Rev. Internat. de Biblio. Med.*, January 25, 1893.

"Organization: In the first place, the night supervision and nursing of the insane is woefully insufficient. We cannot have short watches as on board ship, but with increased numerical strength, we can assign for night duty a larger staff with a supervisor or chief. Make night service longer and day service shorter, but break the night service in two parts, with one hour's suspension of duty between. In small asylums it would be the duty of the supervisor to relieve the subordinates in turn. In large asylums a relieving officer would be told off for duty. The leave of the day staff should be much more liberal than at present.

"The patients should be detailed in small groups for special written observations; each nurse should have a group. Nurses should exchange groups every three months, so that fresh interest is continually kept up, and the patients come under new influences. Change patients from one ward to another oftener than is done at present. Have medical officers and supervisors more in the wards collaborating with the nurses."

The writer recommends the formation of a mental nursery association, and a provident or pension scheme. If linked together under the patronage of asylum boards of management, they can only be followed by decided success.

GENERAL PARALYSIS AT PUBERTY.

Dr. J. Wigglesworth¹³ records two cases occurring in girls at twelve and fourteen years, proving fatal at sixteen and eighteen years, respectively. Both previously intelligent. Both said to have started from a fall; this, however, may have simply been an early symptom. Mental symptoms, those of slowly progressive dementia without grandiose ideas; soon gradual failure of mental power, followed by slow progressive paresis of limbs, until absolutely paralyzed and contractions developed; epileptiform convulsions noted in each. Necropsy showed thickening and opacity of arachnoid, with adhesions of pia mater to cortex (in one case decortication); enormous wasting of convolutions, great atrophy of cortex; whilst in one was an old, thick, organized, subdural membrane. Analysis of these cases and six others published showed the average age at which the disease commenced to be fourteen years, average duration four and one-half years. Five of the eight were girls, a reserve proportion to that shown in adult paralysis; mental symptoms showed preponderance of demented type of general paralysis; signs of puberty did not appear at all or were arrested and tended to disappear; menstruation in females, absent; and arrest of bodily development.

The most prominent probable factors in the production of the disease were heredity and congenital syphilis; traumatism being, perhaps, an additional cause in some cases.

"THE INCREASE OF INSANITY."

Under the head of "The Alleged Increase of Insanity," D. Hack Tuke¹⁴ presents a critical analysis of the statistics of insanity in Great Britain for the last twenty years. He gives the arguments and facts on the affirmative side, as presented by Mr. Corbet (in a forcible article in the *Fortnightly Review*) and others, and follows with his own reasons for denying the alleged increase in insanity. His principal points are thus summarized:

There has undoubtedly been since 1870 a large increase in the number of patients in asylums and workhouses, but proportionately more in the former than in the latter.

There has not been so great, but still a considerable rise, in the *admissions* of patients into asylums during the same periods, after deducting transfers and readmissions.

The advance in the number in detention, although it holds good after allowing for the increase in population, does not prove the increased liability of the community to insanity, seeing the vast accumulation due to a lower death-rate (even since 1870), the chronicity of the disease, and the lamentable tendency to relapse.

The advance in admissions again does not prove increased liability to insanity; as (a) the value and comfort of asylums are increasingly appreciated; (b) there has been a very large number of patients drafted from workhouses to asylums; and (c) there has been an ever-increasing encroachment on the mass of unregistered lunacy which the census shows to exist.

The increase in the number of the insane has taken place among the poorer classes of society.

The increase in the ratio of the insane during the twenty years between 1871 and 1891 has taken place in persons above the age of forty-five, the significance of which lies in the accumulation of chronic cases. On the other hand, there has been a decline during this period in the proportion of cases of mental weakness under twenty-five years of age to the population at the same term of life — a most important circumstance.

The age-distribution of the insane favors, therefore, the conclusion that the increase of insanity is apparent rather than real, being mainly due to accumulation.

That, considerable as has been the increase in the number of the insane, as returned in the censuses of 1871, 1881, 1891, the ratio of increase has been a declining one; for although the rise in the ratio to the population was 7.04 per cent. during the decade of 1871-81, it was only 3.23 per cent. in that of 1881-91.

If these results are, on the whole, reassuring, they are, it must be admitted, nothing to boast of because twenty years of social progress and the advance of medical knowledge ought to have materially lessened the proportion of the insane to the population.

The lesson to carry away from a study of the foregoing statistics is not one of congratulation, but the necessity for making more earnest and definite attempts to diminish the causes of insanity, and to discourage, by every possible means, the extension of the disease by the marriage of individuals of insane stock or who have themselves been deranged in mind, impracticable as I believe it to be to obtain this object by legislation.

F. B. Sanborn,¹⁵ in an article in the same journal, finds, on the other hand, that American insanity is greatly increasing, at least so far as the statistics of the insane in Massachusetts hospitals are an indication. Formerly it was held that the accumulation of the insane greatly in excess of the growth of the population was due partly to better care by which life had been prolonged; partly to better observation, bringing cases to light that were overlooked; finally, to stricter classification of diseases, allowing wider limits to insanity. All these agencies may be allowed up to a certain point; but we long since reached that point in Massachusetts, probably, too, in England and Scotland. Still we find this insane accumulation going on as fast

¹³ British Medical Journal, March, 1893.

¹⁴ Journal Mental Sciences, April, 1894.

¹⁵ Journal Medical Sciences, April, 1894, p. 214.

as fifty years ago, and in the face of influences that ought to yield just the contrary result. He believes that this can only be accounted for on the hypothesis that "occurring insanity" (new cases) is also increasing beyond the population ratio. Starting from the premise that the insane die faster than the sane, he shows that they should relatively diminish just as a feeble race relatively decreases among a sturdier race. Even if they did not recover often, the insane should decrease by virtue of a greater death-rate, unless a constantly increasing number of fresh cases neutralizes the effect of speedier death. But if both the surviving insane and their deaths increase in number steadily (as with us they do), must there not be an increasing source of supply, namely, new cases? In Massachusetts we have a reasonably exact registration of the insane, which shows the first admissions to *any hospital*, and also the number resident in all, the recoveries, deaths, and discharges without recovery. During the past fifteen years the population of the State increased from about 1,725,000 in 1879 to 2,500,000 in October, 1893. Thus, while the population only gained 45 per cent. in that time (or less), the strictly first admissions to *any hospital* — not merely the one making the return — increased from 849 to 1,617, or about 100 per cent.; and the deaths in all the hospitals and asylums of the State increased nearly 130 per cent. The resident insane in these establishments have increased about 94 per cent. or nearly doubled; while the unrecovered insane discharged or transferred each year have exceeded the recoveries and deaths put together, and fully account for the many recommitments in the whole period covered by the statistics [the figures are given in a table]. The presence in Massachusetts of the unrecovered insane that makes the steady accumulation of the chronic class possible and indeed inevitable, while the strictly first admissions (nearly 18,000 or 1,200 a year) have prevented the deaths and recoveries from checking in the least the rapid increase of cases new or old.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

JOHN T. BOWEN, M.D., SECRETARY.

REGULAR Meeting, Monday, March 12, 1894, the President, DR. C. F. FOLSOM, in the chair.

DR. W. F. WHITNEY read a paper on

CIRCROID MYXO-NEUROMA OF THE TONGUE, ILLUSTRATED BY LANTERN SLIDES.

DR. C. W. TOWNSEND read a paper on

MILD FORMS OF NASAL DIPHTHERIA.¹

DR. A. L. MASON: It seems to me that there are two classes of cases which especially interest us in this connection. The first comprises those with membrane in the throat and all the aspects of diphtheria, but in which the specific bacillus of that disease is not found. It is the part of prudence to treat such cases as if they were diphtheria. To the second class belong the mild cases to which Dr. Townsend refers; and the question arises whether from the discovery of the Klebs-Löffler bacillus, in the absence of all visible signs of diphtheria, we must regard and treat such cases always as diph-

theria. Within a fortnight in the general wards at the City Hospital have occurred three cases of that kind in patients convalescing from other diseases, one typhoid, another rheumatic fever and a third pneumonia. They developed sore-throats of the mildest type with reddening of the pharynx and fauces but no membrane, no discharge from the nose. In all three cases the Klebs-Löffler bacillus was found, no appearance whatever otherwise indicating diphtheria. Should we feel obliged in the present state of knowledge to class such cases as diphtheria, and have them isolated at once and treated in the diphtheria wards? I think that we must do so. Whether there is another bacillus morphologically identical in appearance with the Klebs-Löffler bacillus I believe is still an open question. These three cases were transferred, I must say with considerable compunction on my part, to the diphtheria ward, where they were isolated so far as possible. They developed no other symptoms and got well in a few days. If the bacteriological test is decisive we can never feel safe in the treatment of cases of pharyngitis or sore-throat of any kind without it. The temperature in these cases was but slightly raised.

DR. J. H. MCCOLLOM: I have been very much interested in Dr. Townsend's paper, and I think the point he makes of mild cases of the disease is very important, for there can be no doubt that these mild cases are the cause of the prevalence of diphtheria in this community. The various cultures from the Children's Hospital were interesting from the fact that in a large number of cases guinea-pigs were inoculated, and in the majority of instances the pigs died in from twenty-four to forty-eight hours, showing clearly that we were dealing with a virulent form of the Klebs-Löffler bacillus. So far as a bacillus morphologically similar to the Klebs-Löffler found in the mouths of healthy individuals is concerned — the pseudo-diphtheritic bacillus, as it is termed — I am inclined to think that too much stress is laid upon the existence of this organism; for after examining the cultures from 250 throats, I have not found this bacillus. I have in mind the case of a patient who was ill with undoubted diphtheria. The membrane disappeared after four weeks, but a nasal discharge continued from which a culture was made which was found to contain the Klebs-Löffler bacillus. From this a pure culture was made and a guinea-pig inoculated; and the pig died with every indication of death from diphtheria. One week later a second culture was made, and no Klebs-Löffler found. This case had lasted for six or eight weeks, and all this time the individual might have been a source of danger to the community. Fortunately, however, the person was isolated; but in certain localities he would have gone about and spread the disease. Only by means of a bacteriological investigation could the date of his recovery be established. Another case in point is that of what was supposed to be, by the physician in attendance, a case of follicular tonsillitis; but a culture from the throat revealed the presence of the Klebs-Löffler bacillus, the virulence of which was demonstrated by its effect upon a guinea-pig. The patient was isolated, which would not have been the case if a bacteriological examination had not been made. It seems to me that the attempt to throw discredit on bacteriological examinations of the throat by the theory that there is a bacillus morphologically similar to the Klebs-Löffler bacillus found in the throats of healthy individuals, is calculated to do much harm.

¹ See page 513 of the Journal.

In two or three of the cases to which allusion has been made by Dr. Townsend it is to be regretted that so few cultures were made, for it seems to me that two negative cultures made from the throat of a patient who has been ill of diphtheria are not sufficient to prove that he has entirely recovered from the disease, and that he is no longer a source of danger to the community. I think there should be at least four negative cultures made at intervals of two or three days, before we are justified in saying that the individual is no longer a source of danger of contagion. While by this means a patient may be isolated longer than seems to be absolutely necessary, yet it is only by these long periods of isolation that we can ever hope to accomplish anything in stamping out diphtheria.

It has been said that sometimes, even in a marked case of diphtheria, the Klebs-Löffler bacillus is not found; but if the culture is carefully made, and particularly if the precaution is taken to pass the needle through the membrane or under it, the chances of a failure to obtain a culture of the bacillus are so slight as to be worthy of very little consideration. Another point to which Dr. Townsend alluded is that of early diagnosis. There have been several instances in which cultures made from the throats of persons exposed to diphtheria have been found to contain the Klebs-Löffler bacillus before the appearance of any local or general symptoms. The importance of this early diagnosis, so far as treatment is concerned, is manifest.

DR. H. C. ERNST: I do not know that I have anything to add. The work Dr. McCollom has carried on I have watched with great interest. I think some extremely important results are to be obtained from it when completed. The results thus far seem to show that about ten per cent. of the cases submitted to the laboratory for examination are true diphtheria. As to obscuring the diagnosis by the so-called pseudo-diphtheritic bacillus, I am inclined to believe that its occurrence is not sufficiently frequent in clinical work to produce any confusion. I have been very much interested in hearing the cases by Dr. Townsend, and I think this is a question that comes home to all practitioners of medicine. I am very glad to see it brought up.

DR. W. T. COUNCILMAN: I had an opportunity on Saturday of examining anatomically one of the cases of nasal diphtheria. My attention was especially attracted to the nose by the presence of small excoriations on the surface of the skin around the nose, which were covered with a dirty grayish membrane presenting very much the appearance of a diphtheritic membrane. The edges of the nostril were slightly excoriated and had the same membrane on them. In the nasal passages on the mucous membrane there was exactly the same diphtheritic membrane which we find in the pharynx. In the pharynx there was no extensive formation of membrane, although on the tonsils here and there and on the posterior pharyngeal wall there were some very small patches of membrane, but the most of the membrane was on the roof of the pharynx and extending from there into the nasal cavities and especially on each side of the vomer, and it had also extended far up into the upper turbinate bones. The diphtheria bacilli were found in cultures made from the excoriations around the nostrils and also in the membrane of the nose.

DR. M. PRINCE: I should like briefly to mention an epidemic of diphtheria which occurred some years

ago in some of the homes for children in this city, and which I had an opportunity of investigating. If I remember rightly there were 50 to 60 cases of diphtheria. These cases were divided up by the doctor in charge of the homes into three classes, and each class was in a room by itself. In one room all those that showed no membrane in the throat and that showed simply symptoms of coryza; and in another room all those with membrane, but mild cases; and in the third room the malignant cases. In these days we had no test, of course, as this one of determining whether they were diphtheria; but there was one piece of evidence which showed that these nasal cases were diphtheria, that is, every day some of those children with the nasal discharges came down with membranes in the throat and would be transferred to the room of children with membranes. That experience impressed me then with the frequency of the nasal form, and how difficult it was to distinguish the mild cases. I have been impressed with the numbers of these mild cases that exist in tenement-houses. I would also mention an epidemic of diphtheria started in Nantucket by a case of diphtheria in a physician who was supposed to be well and went to Nantucket and gave rise to an epidemic.

DR. E. M. BUCKINGHAM: In connection with the case of mine that Dr. McCollom reported, I should like to add that while coryza lasted many weeks, yet within a short time of the disappearance of the bacilli there was marked diminution, and the boy soon got well. With reference to nasal diphtherias I should say there are a number of nasal diphtherias that are not very sick, just as there are a number of tonsillar diphtherias not very sick, but I should mark the distinction between those that are sick, and those not very sick, not so much on the line between primary and secondary as upon the line between anterior and posterior nasal diphtheria.² I think that any of these cases may at any moment become dangerously ill. The temperature of diphtheria in my experience is pretty generally not very high unless the case is septic.

DR. GEO. B. SHATTUCK: It seems to me if the diagnosis of diphtheria is to be settled by the presence of the Klebs-Löffler bacillus without reference to other symptoms at all, and people having this bacillus in the naso-pharynx are to be isolated and treated as if they had diphtheria, it brings up a pretty wide question with reference to the manner of dealing with all those who come in contact with such people. If the mere fact that a person carries the Klebs-Löffler bacilli about the person internally or externally necessitates isolation, we shall hardly know where to stop in our measures directed to this end. It seems to me there is a possibility of going too fast and too far with reference to this bacillus as well as with reference to the bacillus of tuberculosis.

DR. TOWNSEND: A weak solution of peroxide of hydrogen was used in all the cases.

There was one thing I intended to speak of, and that was a method by which infection takes place. It seems to me it might arise from the common habit among children of picking the nose. If there were any Klebs-Löffler bacilli lying about the wards, the child in picking its nose might inoculate the mucous membrane. I

² On the morning after the meeting, I counted twelve children in the City Hospital all playing together with great spirit. All had coryza with Klebs-Löffler bacilli in the nose; and in all these cases coryza, which was the only evidence of disease remaining, was secondary to severe disease in the posterior nares and throat, all trace of which had disappeared. — E. M. B.

think on that account primary nasal diphtheria must be much more common than is supposed.

Dr. McCollom spoke of passing the needle through the membrane in order to get at the Klebs-Löffler bacilli. That brings up the question of using the swab or needle. It seems to me as if the swab would collect more and stand a better chance of finding the bacilli. But if the bacilli are at the bottom of the membrane, how can you get them on the swab?

DR. C. F. WITHINGTON reported

A CASE OF AMŒBIC DYSENTERY.*

DR. W. T. COUNCILMAN: The amœbæ found in this case were very numerous and active. They were first seen on examination of the fæces by my assistant at the City Hospital, Dr. Emerson, who had had no previous experience in looking for them. They appeared to me to be larger than usual, the size varying a great deal. As a rule, they are eight or ten times the diameter of a red corpuscle. We can always recognize in them a very granular interior, which is surrounded by a homogeneous portion. The granular interior is called *endosarc* and the homogenous external portion *ectosarc*. In the endosarc there are always large vacuoles filled with fluid, but I have never found anything analogous to the contractile vesicle of the ordinary fresh water amœba. The movement in some cases is quite active, appearing first as a protrusion of the ectosarc, which is followed by the flowing of the endosarc into the protrusion. The movement sometimes is progressive, and the organism will, in a few moments, move across the field of the microscope.

The amœbæ always contain various foreign substances, and it is very common to find red corpuscles within them. In addition to the red corpuscles, epithelial cells (or fragments of these) are frequently found; but it is rare that leucocytes are enclosed in them. The nucleus cannot be seen in unstained specimens, and it is made evident by a few staining reagents. The dysentery which is produced by the amœbæ is always of a perfectly definite type, and can be distinguished anatomically from any of the other forms.

Anatomically, dysentery can be divided into three varieties; amœbic, diphtheritic, and simple or catarrhal. The latter, probably, represented etiologically different forms not included under the amœbæ and diphtheritic. As far as I have been able to learn from observation and from literature, the great epidemics of dysentery seem to have been always of the diphtheritic form. In this there is necrosis of the mucous membrane extending more or less deeply, combined with fibrinous exudation. It may or may not be combined with ulceration. Ulceration is due to the casting off of the necrotic tissue and fibrin. The ulcers are irregular in form and may be superficial or may extend down into the muscular coat. In the simple and catarrhal dysentery there are two more or less distinct forms. In the first the follicles of the intestines are chiefly affected. These become enlarged, and suppuration may take place within them. They may rupture on the surface, giving rise to small ulcers which extend some distance into the mucous membrane. The most common form, and which is frequently combined with this affection of the follicles, is purulent catarrh of the mucous membrane, combined with more or less erosion of the surface. The ulcers are superficial, in many cases do not extend through the mucous membrane.

They are always much broader on the surface than on the bottom.

In the amœbic dysentery we have a type which is anatomically distinct, and may be distinguished at once from either the simple or diphtheritic form. In this type the stress of the disease does not appear to fall on the mucous membrane, but it affects the submucosa, the mucous membrane being involved secondarily. Neither the glands of the intestines or the follicles appear to take any part in the process. A great swelling of the intestines is the most marked feature of the disease. This is due to the infiltration of the submucosa. The swelling not only affects the intestine everywhere, but here and there there are nodular projections. The ulcers begin in the interior of the nodules by the submucous infiltration breaking through to the mucous surface. The ulcers always have deep undermined edges and sometimes long sinuous tracts, communicating with adjacent ulcers here found in the submucosa. Sloughs of the mucous membrane are frequently found in this form of dysentery, and the pathological conditions produced are extremely interesting. There is not so much distinct suppuration of the tissues as simple softening with following ulceration. The main feature appears to be softening of the intercellular connective tissue.

This case was not accompanied by abscess of the liver. The specimens which I show here have been preserved in alcohol, and they do not show the typical lesion as well as they ought when fresh.

Recent Literature.

A Practical Treatise on Diseases of the Hair and Scalp. By GEORGE THOMAS JACKSON, M.D. New, revised and enlarged edition. New York: E. B. Treat. 1894.

Dr. Jackson's book on diseases of the hair and scalp has reached its second edition. We find the book considerably enlarged and amended, and the little that has been added to our knowledge of this subject during the last five years, receives due notice. New illustrations have been added and the valuable bibliography at the end of the book has been brought down to January, 1893. It more than retains its place as a clear exposition of what is known of diseases of the hair and scalp.

A Hand-Book of Ophthalmic Sciences and Practice. By HENRY E. JULES, F.R.C.S., Ophthalmic Surgeon to St. Mary's Hospital. Pp. 549, with illustrations. 2d edition. Philadelphia: Lea Brothers & Co. 1893.

This is a second edition of a work previously reviewed in this column, and is reproduced with some additions and alterations. The colored plates, especially those relative to external diseases of the eye are new, but are not a great improvement over those in the first edition, which were far from good. The text is clearly printed, and headings and sub-headings printed in bold type and italic in a manner that makes the book exceedingly convenient for ready reference. The style of the book is interesting, and it is admirably adapted to the purpose for which it was evidently intended, a reference hand-book in a physician's library.

* See page 516 of the Journal.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, MAY 24, 1894.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

HAFFKINE'S METHOD OF INOCULATION
AGAINST CHOLERA.¹

THE preventive inoculation against cholera which Professor Haffkine is putting to so thorough a test in India, has already given sufficient evidence of its being of some value, to make an account of the methods employed of interest.

Two preparations are made of the "vaccine" as the virus or antitoxine is for some curious reason called—one an attenuated form, obtained by successive cultures in nutritive media, and a strong virus obtained by a culture on a solid medium, as agar-agar, after several generations have been passed through guinea-pigs. The vaccines of normal strength are diluted for injection with sterile water, and the emulsion carefully examined.

The skin of the patient is made aseptic over the seat of injection, which is about an inch and a half above the crest of the ilium and three inches posterior to the anterior superior spine. The first injection, which is occasionally the only one required, is always made with the weaker preparation. For the first two hours no effect is noticed, but from the third to the twelfth hour there is a rise of temperature, a feeling of malaise and more or less tenderness over the point of inoculation. During the next twenty-four hours the general symptoms disappear, the painful induration lasting for a few days.

Beyond a temporary reddening at the point of inoculation no alteration of the surface of the skin is produced. No disturbance of the digestive functions is, as a rule, produced, and no change in diet or occupation is necessary. In a few persons there is at first chilliness and a slight diarrhoea.

The amount of fever varies, and is taken as an indication of the natural amount of resistance of the patient against cholera, high fever being considered as a proof of strong natural resistance. In this case the second inoculation is sometimes adjudged unnecessary, or is made with a small dose of the strong virus. On

¹ Indian Medical Gazette, April, 1894.

the other hand, when the fever produced by the first inoculation is not perceptible, this is taken as a proof of susceptibility to the disease, and a second inoculation is given with an increased dose, five or more days after the first, on the opposite side of the body, the stronger virus being used. The symptoms ensuing are essentially the same as those caused by the first dose, varying only as the dose is larger or smaller. In the cases where the first dose is followed by a fall of temperature, diarrhoea or other mild choleraic symptoms, the second injection is always given with an increased dose, but notwithstanding such larger dose the choleraic symptoms are produced exclusively by the first inoculation, fever being the only symptom after the second inoculation.

RAILWAY SPINES AND SURGEONS.

THE seventh annual convention of the National Association of Railway Surgeons, held two weeks ago in Galveston, Tex., was a most entertaining gathering. The meeting was held in Harmony Hall, which was about all the harmony there was.

Nevertheless, Mr. Clark Bell, of New York, chose as the subject of his address "Railway Spine," which he characterized as the Nemesis of the modern railway. Like all proper Nemeses, it had an origin and an aim. As a means of procuring enormous verdicts from railway corporations in accident cases, it has baffled both railway surgeons and counsel, and, vampire-like, sucked more of the blood of corporate bodies and railway companies than all other cases combined. This vampire-like Nemesis has also the property of the philosopher's stone, of turning injuries to golden opportunities for wealth. For the better accomplishment of its purpose, this Nemesis first showed itself as a plant sprouted on English soil after the era of steam, but rapidly growing in its infancy to a tree like a banyan, so that it has been "an incubus, and almost a parasite, upon the modern railway." "Avarice and greed have been the rain and dew which have watered" this Nemesis morn and eve.

He most properly considers that "the time has come when the profession of surgery should define this injury so that courts, counsel and juries may know and locate and apply to it those tests which are insisted upon in regard to all other physical injuries. It should be brought out of the shadow into the sun, out of the darkness into the light, out of the mysterious into the actual—the real." The legal profession is particularly averse to a Nemesis; and consequently both bench and bar are desirous of having an organization (such as that of railway surgeons) "frame a correct definition of the disease, if it exists, and to so describe and characterize it with precision that not only judges and lawyers may know what it is with certainty, but that the average jurymen shall be able to do so."

One of the great duties of the near future for railway

surgeons is to establish definitions, rules and limitations of special injuries, real and imaginary, and so effectually put a stop to the enormous verdicts which are sapping the reddest life-blood of the Nemesis-ridden modern railway.

The afternoon session, which was devoted to the election of officers, had a Nemesis (or something else) to trouble it, for it was a most exciting and spontaneous session, especially spontaneous in the calling of names and the exchange of complimentary criminations. Finally, the new officers were elected, with a general belief that the ballot-box was really never stuffed, and that nobody had really falsified or borne ill-will.

The morning session the next day began at 9 A. M. with divine invocation; but before then the spines of the railway surgeons had recovered their normal steadiness and control, and they all had a hop—that is, the surgeons and their families, not the spines nor the Nemesis. The women were fair, the men were brave. Our Texan authority informs us that “Hundreds of couples danced to the time of rhythmic strains in the parlors of the Beach Hotel. The occasion was *recherche*. It was perfect.”

COMPULSORY VACCINATION.

A DECISION of public interest was rendered by Justice Wm. J. Gaynor, in the Supreme Court of Brooklyn, on May 18th. Since the outbreak of small-pox in that city about three months ago special vaccinators, under the direction of Health Commissioner Emery, have vaccinated over one hundred thousand persons, and in many instances it was against the protest of the individual. The question of compulsory vaccination was not brought before the courts, however, until two expressmen were forcibly quarantined in a stable for refusing to be vaccinated. These men secured a writ of habeas corpus, and it was upon this that the decision of Justice Gaynor was handed down.

In the course of it, he says: “To justify this action the commissioner makes written return to the writ that, as the petitioners are expressmen, and therefore go about and carry goods, they are, in his judgment, ‘unusually exposed’ to small-pox contagion. Therefore he ordered them to be vaccinated, and they refusing to submit their bodies to vaccination, he ordered quarantine to be placed upon said premises and that said persons be detained therein until they consent to be vaccinated. If the commissioner had the power to imprison an individual for refusing to submit to vaccination, I see no reason why he could not also imprison one for refusing to take some dose. But the legislature conferred no such power upon him, if indeed it has the authority to do so. The law empowers all health boards to require the isolation of all persons and things infected with or exposed to contagious or infectious diseases. There is no claim that the petitioners are infected or have been actually exposed to infection. Even if they were subjects for isolation by

reason of infection or exposure thereto, they could only be detained while such conditions existed, and not indefinitely until they yielded their bodies to vaccination. . . . If the legislature desired to make vaccination compulsory it would have so enacted. If, however, it should be made by the legislature a criminal offence to refuse to be vaccinated, it may well be suggested that the accused under such a law would have to be tried, like all other offenders, in a competent court and after the due process of law which is guaranteed every one by the constitution.”

The petitioners were discharged.

MEDICAL NOTES.

THE HOSPITAL SUPPLY OF NEW YORK.—New York City has eighty-one hospitals, containing ten thousand eight hundred and seven beds, of which eighty-five hundred are free.

EDITOR OF THE ARCHIVES OF PEDIATRICS.—Dillon Brown, M.D., Adjunct Professor of Pediatrics at the New York Polyclinic, will take the editorial charge of the *Archives of Pediatrics*, beginning with the July issue.

A SUMMER SCHOOL OF NEUROLOGY AND PSYCHIATRY.—A summer course of clinical and laboratory study of nervous and mental diseases is to be given for six weeks, beginning June 4th, at the Illinois Eastern Hospital for the Insane.

PROLONGED LIFE AFTER PERFORATION OF THE HEART.—A man was shot in the chest recently in Erie, Pa., and lived for seventy hours afterwards. A post-mortem examination of the body showed that the bullet had passed through the left ventricle.

THE CZAR'S INTEREST IN THE NEXT INTERNATIONAL MEDICAL CONGRESS.—The Czar of Russia, who has from the first shown great interest in having the next International Medical Congress meet in Russia, has signified his intention of contributing fifty thousand roubles towards the expenses of the meeting.

THE AMERICAN MEDICO-PSYCHOLOGICAL ASSOCIATION.—At the last meeting of the American Medico-Psychological Association, held in Philadelphia May 17th, the following officers were elected: President, Dr. Edward Cowles; Vice-President, Dr. Richard Dewey; Secretary and Treasurer, Dr. Henry M. Hurd; Auditor, Dr. A. R. Moulton.

STATE BOARD OF MEDICAL EXAMINERS OF NEW JERSEY.—The last meeting of the State Board of Medical Examiners of New Jersey to examine candidates desiring to practise medicine in that State under the present law, will be held June 14th at the capitol at Trenton. The new law, which goes into effect July 4, 1894, requires all candidates to have a competent common-school education, to be graduates in medicine, and to have studied at least four years and to have taken three full courses of lectures before being admitted to an examination.

THE LYNCHING RECORD. — During the year 1893 there were two hundred persons put to violent death by lynching in the United States, an increase of one over the year 1892. Of this number, thirty were white persons and one hundred and fifty negroes (four of them women). Fifty-four were killed for rape; fifty-seven for murder; the rest for various smaller crimes. During the last twelve years nearly two thousand negroes have been shot, hanged, or burned to death by mobs.

THE NEW JERSEY STATE HOSPITALS FOR THE INSANE. — This is the present position as to the State Hospitals for the Insane in New Jersey, and there is great desire on the part of medical men to have the Governor rightly interpret the law in the appointment of new officials: "An act has been passed, and is now in the hands of the Governor, which makes vacant every position in connection with the State Hospitals for the Insane; and as it provides for a non-partisan Board of Managers, and as this is in accordance with a suggestion made by the Governor in his annual message, it is fair to presume it will become a law."

MEAT-EATING, VEGETARIANISM AND MANNERS. — A good deal has been said recently about the bad temper caused by meat-eating and by implication of the mild gentleness of those who subsist on roots and herbs. The *National Popular Review* is moved to champion the flesh-devouring man and says: The Hindoo professional assassin or murderer is probably as cold-blooded and as ferocious a being as one may imagine. The Chinese are great vegetarians. Rice, beans in the green state, cabbage and large spinach, water-cresses and fruits enter largely into their diet. They are besides very fond of fish, and yet there is nothing more bloodthirsty and bellicose, more wild or more unmanageable than the Chinaman when aroused. On the other hand, the native Californians, like the dweller on the wild pampas of South America, who lived on an exclusive beef diet, were generous, self-composed, and not in the least given to either strife or blood-shed.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — During the week ending at noon, May 23, 1894, there were reported to the Board of Health of Boston the following numbers of cases of acute infectious disease: diphtheria 39, scarlet fever 17, measles 23, typhoid fever 23, small-pox 0. There is one patient with small-pox at the Canterbury Street Hospital, two at Gallop's Island; patients nearly well; no deaths.

REQUESTS TO HOSPITALS. — The will of the late Nancy Bartlett, of Milford, Mass., bequeaths five hundred dollars each to the Perkins Institution for the Blind and the Children's Hospital of Boston.

A FILTER PLANT FOR THE PROVIDENCE WATER-SUPPLY. — The city government of Providence, R. I., has taken the preliminary steps towards the construction of a large and complete filtration plant for its public water-works.

BOVINE TUBERCULOSIS IN JAMAICA PLAIN, MASS. — Several valuable blooded cows belonging to private herds in Jamaica Plain have been found seriously affected with tuberculosis, and have been killed.

A HOSPITAL FOR CONTAGIOUS DISEASES IN SOMERVILLE, MASS. — The city of Somerville has fitted up a small building on North Street for patients with contagious diseases. It is a one-story building, containing four rooms.

THE BOSTON CITY HOSPITAL EXAMINATION FOR HOUSE-OFFICERS. — There were thirty-nine candidates for appointment as house-officers at the Boston City Hospital at the examination last week. There were nine vacancies to be filled.

AN EMERGENCY HOSPITAL FOR EVERETT, MASS. — A meeting was held in Everett last week to consider the establishment of an emergency hospital. The proposed articles of incorporation were referred for final acceptance to a later meeting.

MASSACHUSETTS MEDICAL SOCIETY. — The annual meeting of the Massachusetts Medical Society will be held on June 12 and 13, 1894. Attention is called to the fact that the Meetings of the Sections at 2 P. M., and the Shattuck Lecture at 8 P. M., on Tuesday the 12th of June, will be at the Harvard Medical School. The Meeting, the Annual Discourse and the Dinner, on Wednesday, June 13th, will be in Mechanic Building.

A SMALL-POX HOSPITAL FOR CHELSEA, MASS. — The occurrence of a case of small-pox in Chelsea has led the Board of Health of that city to purchase for a small-pox hospital a building on Bellingham Street, which has been occupied for some time as a tenement-house. It contains thirteen rooms, and is well adapted for its purpose, having formerly served as a small-pox hospital before being used as a dwelling-house. It is about five hundred feet from any other houses.

BARNSTABLE DISTRICT MEDICAL SOCIETY. — The annual meeting of the Barnstable District Medical Society was held at Hyannis, April 18th, and the following officers were elected for the coming year: President, Horatio S. Kelley, Jr., of West Dennis; Vice-President, Edward E. Hawes of Hyannis; Secretary, F. W. Pierce of Marston's Mills; Treasurer, George N. Munsell of Harwich. At the close of the meeting the Society was entertained at dinner by Dr. G. W. Doane.

A DINNER TO DR. E. H. BRADFORD. — A dinner was given to Dr. E. H. Bradford, at the Union Club, on Tuesday evening, May 22d, by his former colleagues and associates of the Boston City Hospital, to mark their sense of the loss which the hospital and they themselves have sustained by his resignation from the hospital staff, of which he has been a most valued member for fourteen years. The President and Secretary of the Board of Trustees, the Superintendent, several members of the Consulting Board,

and almost all the members of the active staff, were present. Dr. D. W. Cheever, the President of the hospital staff, presided very felicitously; and many informal speeches testified to the flattering appreciation in which the guest of the evening is held by his former colleagues. Dr. Bradford was presented with a cup bearing a suitable inscription.

NEW YORK.

STERILIZED MILK FOR THE POOR.—Mr. Nathan Strauss, who has long been identified with philanthropical work in the city, has opened four depots in the tenement-house districts for the sale of sterilized milk for the benefit of the poor. His aim is to diminish the death-rate among children in summer, and the sterilized milk will be sold at a lower-rate than ordinary milk can be procured elsewhere. In addition, powdered barley and oat-meal for the purpose of preparing food for infants will be sold at the lowest possible prices. Last summer Mr. Strauss maintained but a single depot of this kind, and the result seemed to be very satisfactory.

TUBERCULOUS MEAT.—The investigation of the case recently reported in which the four quarters of a tuberculous cow were seized at West Washington Market showed that a number of other cows in the herd at Goshen, Orange County, from which the animal came are affected with tuberculosis. During the year 1893 the quantity of meat condemned in the city of New York amounted to 1,175,287 pounds, against 2,862,144 pounds in 1892, when the quantity was about 90,000 greater than in 1891. For the three years the average was nearly three tons a day. In addition to the various markets, the meat inspectors visit daily all the slaughter-houses in the city. They not only see the killing done, but insist that the places are kept clean, the refuse promptly removed, and every thing done to make the slaughter-houses as free from anything objectionable from a sanitary standpoint as is possible. No one is permitted to slaughter cows except between the hours of 8 A. M. and 5 P. M., in the presence of an inspector. If a cow is found to be affected with tuberculosis the carcass is promptly condemned and sent to the offal dock. Then the case is followed back, if possible, to the farm from which the animal came and all necessary precautions are taken to prevent any more cattle being brought from the place, while the officials of the State Board of Health are notified of the condition of affairs.

THE NEW YORK STATE COLONY FOR EPILEPTICS.—In a recent issue there was a brief notice of the act of the New York Legislature establishing a colony for epileptics in that State. The very great value of such an establishment, and the important advance it marks in State care of these unfortunate persons, makes a more extended notice of interest. A Board of Five Managers is provided for, to serve without salary and to meet at the colony at least once a month. The Governor appointed as the Board of Managers: Dr. Frederick Peterson, of New York;

Mrs. C. F. Wadsworth, of Genesee; George M. Shull, of Mount Morris; Dr. Charles E. Jones, of Albany, and W. H. Cuddeback, of Buffalo. At its organization in Albany on the 3d of May, the Board made Dr. Frederick Peterson, President, and George M. Shull, Secretary. The law requires that all of the buildings put up shall be on the village plan; and an important provision in this bill is that the Managers may accept any bequests of persons interested in the welfare of epileptics, and it is believed that many charitable wealthy people will build cottages upon the splendid sites on the tract, to bear their names and exist as lasting memorials to their desire to serve humanity in this wise. A medical superintendent, steward, matron, pathologist, nurses, school-teachers, teachers of various industries and arts, and so on, are to be appointed as needed; but the colony will not be ready probably to receive patients before the autumn of 1895. It is thought that the colony will ultimately number fifteen hundred to two thousand members. As soon as possible the six hundred epileptics in the various county almshouses will be taken in charge. Later, private patients will be received at prices corresponding to the accommodations asked for. It is sure to become self-supporting in the course of time, and to grow into an industrial and agricultural village that will more than rival the similar and famous colony at Bielefeld, Germany, upon which to a certain extent this is modelled.

Miscellany.

THE OVER-ZEALOUS THERAPEUTICIAN.

IN his address before the International Medical Congress, Professor Stokvis, speaking of the vagaries of modern pharmacy and chemo-therapeutics, said:

"The reason of the present situation—or imbroglia—is obvious. By the side of the chemist stands the busy practitioner, or the overwrought professor. Both are oppressed by the sense of insufficiency of their art; neither has the time to observe, reason and conclude. It is the professor who publishes with railroad haste his observations and impressions, for he is ever haunted by the fear lest another should precede him in the new discovery. He it is who makes others follow, sheep-like, in the wake. He constitutes himself a bustling *impresario*, always on the lookout for a new sensation, agitating himself and the public, and, finding that he has before him a fickle, unquiet, impatient audience, he hastens to deal with new subjects, if not every day, at least every week. During the year 1893, sixty-eight new chemical products have been recommended to me, this figure not being inclusive of entirely new drugs or their active principles. In each case we are told that the new product is of the very first importance, of exceptional therapeutic value, and perfectly harmless. *Fistula dulces canit volucres dum decipit aucups.* The wise man will not be taken in. He will be guided by therapeutic teaching such as that of the immortal Baglivi, the author of the pregnant phrase, '*Ars tota in observatione*,' or by the teaching of my honored friend, Professor Semmola, delivered with all

¹ Lancet, April 21, 1894.

his *maestria Italianni* from his chair in the University of Naples, a university which has lately set a glorious example to Europe by proclaiming that a drug that is efficacious cannot be harmless. Nearly all new remedies have their period of success, be it but for an hour, and this is due to 'suggestions,' either by medical men or patients: but, with few exceptions, these panaceas are doomed to be laid aside as forgotten and antique curiosities."

CHARLES C. PIKE, M.D.

RESOLUTIONS OF THE ESSEX SOUTH DISTRICT MEDICAL SOCIETY.

Whereas, Dr. Charles C. Pike, an honored and beloved member of the Essex South District Medical Society has, in the infinite wisdom of God, been called from among us in the prime of his manhood; therefore, be it

Resolved, That in his death we recognize the great loss to this Society, to the community in which he lived, as well as a personal bereavement to those of us who knew and loved him so well; and we desire to pay to his memory a tribute of sincere respect, expressing our admiration of his attainments as a physician and of his manliness and purity of character.

Resolved, That we extend to his wife and family our heartfelt sympathy at the great grief which has come upon them.

Resolved, That a copy of the above be presented to the family of the deceased, and also be entered on the records of the Society.

(Signed)

C. A. CARLTON,

Correspondence.

"THE MEDICAL REGISTRATION BILL IN THE MASSACHUSETTS LEGISLATURE."

BOSTON, May 19, 1894.

MR. EDITOR:—The worst of this bill is that it will benefit only the quacks; that is to say, if any of them will cram so as to be registered, which may be doubted, generally. Every M.M.S.S. is registered on or before he becomes a member (in fact, even though no word is said about it at the time). Formerly, the candidate, after being licensed, had to wait three years and then ask to become a member. Now, he does not wait a moment, but is licensed and admitted at the same moment, on his passing the examination successfully. The Society does all this for him, and nobody can take this right or power from the Society without its consent, and no one can prevent its members from practising medicine and surgery while residing in Massachusetts. The bill can give no further right to you or to me than we now have, even if we ask its agents to register us, which I trust we shall not do.

The bill should be entitled "An act to encourage the practise of quackery by dignifying persons illegally using the designation 'M.D.'!" It will only degrade the regular profession in as far as any of its members permit their names to be registered with these quacks; and, as for the public, it will be worse off than ever in endeavoring to distinguish by title the reputable from disreputable practitioners of medicine.

Strange that such a bill should be allowed to pass with so little opposition; the *Boston Advertiser*, only, has indicated some of its many "defects."

The intimation that the medical member of the Senate is the author of the bill is an absurdity not to be encouraged.

Very truly yours, *

METEOROLOGICAL RECORD.

Deaths reported 2,351: under five years of age 881; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fever) 331, acute lung diseases 375, consumption 304, diphtheria and croup 163, diarrhoeal diseases 33, scarlet fever 32, measles 30, whooping-cough 26, typhoid fever 26, erysipelas 12, malarial fever 10, cerebro-spinal meningitis 7, small-pox 4.

From measles New York 14, Brooklyn 10, Cleveland 4, Philadelphia and Boston 1 each. From whooping-cough New York 6, Brooklyn and Cleveland 5 each, Philadelphia 4, Washington 3, Boston, Nashville and Fall River 1 each. From typhoid fever Philadelphia 11, Brooklyn 5, New York and Cincinnati 3 each, Cambridge, Lynn, Holyoke and Newburyport 1 each. From erysipelas New York 7, Philadelphia and Brooklyn 2 each. From malarial fever New York 5, Brooklyn 4, Nashville 1. From small-pox New York 3, Brooklyn 1.

In the thirty-three greater towns of England and Wales with an estimated population of 10,458,442, for the week ending May 8th, the death-rate was 17.2. Deaths reported 3,446: acute diseases of the respiratory organs (London) 237, measles 200, whooping-cough 189, diphtheria 80, scarlet fever 51, fever 38, diarrhoea 29, small-pox (London 6, Wolverhampton, Birmingham and Nottingham 1 each) 9.

The death-rates ranged from 11.0 in Bolton to 31.3 in Wolverhampton; Birmingham 19.9, Brighton 14.9, Croydon 11.2, Huddersfield 13.2, Hull 14.5, Leeds 16.2, Leicester 14.9, Liverpool 21.3, London 17.2, Manchester 18.8, Newcastle-on-Tyne 18.8, Nottingham 18.9, Portsmouth 11.3, Sheffield 15.4, Sunderland 17.2.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 12, 1894, TO MAY 18, 1894.

Leave of absence for four months, on surgeon's certificate of disability, is granted MAJOR VAN BUREN HUBBARD, surgeon.

Leave of absence for three months, on account of disability, with permission to leave the Department of Texas, is granted CAPTAIN ALONZO R. CHAPIN, assistant surgeon.

MASSACHUSETTS MEDICAL SOCIETY.

ONE HUNDRED AND THIRTEENTH ANNIVERSARY.

The annual meeting will be held at 9 o'clock A. M., Wednesday, June 13, 1894, in the building of the Massachusetts Charitable Mechanic Association, on Huntington Avenue, Boston.

Meetings of Sections will be held at the Harvard Medical School Building, corner of Boylston and Exeter Streets, on the preceding day, Tuesday, June 12th.

TUESDAY, JUNE 12TH.

The laboratories and the anatomical museum of the Harvard Medical School will be open to Fellows of the Society during the day.

At 10 A. M., the Fellows of the Society are invited to visit the Massachusetts General Hospital, on Blossom Street; the Boston City Hospital, on Harrison Avenue; the Children's Hospital, on Huntington Avenue, and the Carney Hospital, South Boston.

Section in Medicine, Harvard Medical School, 2 P. M. — Dr. F. C. Shattuck, of Boston, Chairman; Dr. G. G. Sears, of Boston, Secretary. "The Protective Power of Vaccination." By Dr. J. H. McCollom, of Boston. "The Technique of Vaccination." By Dr. W. N. Swift, of New Bedford. "Radical Differences in Methods of Cultivation of Vaccine Lymph." By Dr. S. W. Abbott, of Wakefield. Discussion by Drs. J. F. A. Adams, of Pittsfield; L. F. Woodward, of Worcester; J. B. Field, of Lowell.

Section in Surgery, Harvard Medical School. — Dr. F. K. Paddock, of Pittsfield, Chairman; Dr. C. L. Scudder, of Boston, Secretary. "The Cure of Carcinoma of the Breast by Operation." By Dr. W. T. Bull, of New York City. Discussion by Drs. D. W. Cheever, J. C. Warren, G. W. Gay, M. H. Richardson, of Boston; T. F. Breck, of Springfield; S. H. Weeks, F. H. Gerrish, of Portland, Me.; J. B. Wheeler, of Burlington, Vt. *Shattuck Lecture, Harvard Medical School, 8 P. M.* — "The Range and Significance of Variations in the Human Skeleton." By Thomas Dwight, M.D., of Nahant. The lecture will be illustrated by many specimens.

COUNCILLORS' MEETINGS.

The Annual Meeting, at 11 o'clock A. M., Tuesday, June 12, 1894; Stated Meetings on Wednesday, October 3, 1894, and on Wednesday, February 6, 1895, at the Medical Library, No. 19 Boylston Place, Boston.

EXHIBIT.

In the Exhibit Hall, Mechanic Building, there will be an exhibit of crude drugs and preparations of the United States Pharmacopoeia, prepared by the students of the Massachusetts College of Pharmacy, to illustrate the revised edition of 1890.

The State and other Boards of Health will make an exhibit pertaining to Sanitary Science. That of the State Board will be the one shown at the World's Fair.

There will be the usual exhibit of surgical instruments and apparatus, electrical appliances, books, etc.

The Crematory of the Massachusetts Cremation Society, at Forest Hills, will be open to Fellows of the Society for inspection from 2 P. M., to 4 P. M., Tuesday, and can be reached by electric cars or by the Providence R. R. to Forest Hills Station.

WEDNESDAY, JUNE 13TH.

Annual Meeting, Cotillon Hall, 9 A. M. — Business of the Annual Meeting. "Ichthyol in Gynecology." By Dr. Malcolm Storer, of Boston. "Chronic Inflammation of the Seminal Vesicles." By Dr. G. W. Allen, of Boston. "The Frequency of Puerperal Sepsis in Massachusetts, its Diagnosis and Efficient

Treatment." By Dr. Edward Reynolds, of Boston. Discussion by Drs. C. M. Green, of Boston; E. H. Stevens, of North Cambridge.

Introduction of delegates.

The Annual Discourse, 12 M. — By R. H. Fitz, M.D., of Boston.

The Annual Dinner, 1 P. M. — At the close of the discourse the annual dinner will be served.

J. C. WHITE, M.D., President.

E. J. FORSTER, M.D., Treasurer.

51 Massachusetts Avenue, Boston.

F. W. GOSS, M.D., Recording Secretary.

217 Warren Street, Roxbury.

SOCIETY NOTICES.

AMERICAN MEDICAL EDITORS' ASSOCIATION. — The annual meeting of this Association will be held at the Palace Hotel, San Francisco, Cal., during the meeting of the American Medical Association.

C. H. HUGHES, M.D., President.

GEO. M. GOULD, M.D., Secretary.

I. N. LOVE, M.D., Chairman Com. Arrangements.

RECENT DEATH.

MAURICE KING HARTNETT, M.D., M.M.S.S., died in Boston, May 14, 1894, aged seventy years. He graduated from the Harvard Medical School in the class of 1859.

BOOKS AND PAMPHLETS RECEIVED.

The Seventieth Annual Report of the Officers of the Retreat for the Insane at Hartford, Conn., April, 1894.

The Tubercular Diathesis Controlled by Gold and Manganese in Combination. By J. Blake White, M.D. Reprint. 1894.

About Mushrooms; A Guide to the Study of Esculent and Poisonous Fungi. By Julius A. Palmer, Jr. Boston: Lee & Shepard. 1894.

Zur Behandlung der Lungentuberculose mittels Kochscher Injectionen. Von Dr. E. Thörner, Sanitätsrath in Berlin. Berlin: S. Karger. 1894.

Catalogue of the Library of the Royal Medical and Chirurgical Society, Supplement VII, Additions to the Library 1892-3. London: Printed for the Society. 1893.

Emergency and Hygienic Notes for the Militia. By William H. Devine, M.D., Surgeon, Ninth Regiment, Massachusetts Volunteer Militia. Boston: Damrell & Upham. 1894.

The Drainage of Fitchburg, Comprising Remarks on the Subject of Drainage in General and the Disposal of Sewage and other Waste. By Clarence W. Spring, M.D., City Physician, Fitchburg.

Transactions of the New York State Medical Association for the Year 1893. Volume X. Edited for the Association. By E. D. Ferguson, M.D., of Rensselaer County. Published by the Association.

China, Imperial Maritime Customs, II Special Series: No. 2, Medical Reports for the Year ended March 31, 1890, 38th and 39th issues. Shanghai: Published by order of the Inspector-General of Customs. 1894.

Medico-Chirurgical Transactions. Published by the Royal Medical and Chirurgical Society of London. Volume the seventy-sixth. (Second series, volume the fifty-eighth.) London: Longmans, Green & Co. 1893.

On the Features which Distinguish Epidemic Roseola (Rose-rush) from Measles and from Scarlet Fever. By Clement Dakes, M.D., B.S., Lond., M.R.C.P., Physician to Rugby School, etc. London: J. & A. Churchill. 1894.

Hydatid Disease. Vol. II. By the late John Davies Thomas, M.D. (Lond.), F.R.C.S. (Eng.). A Collection of Papers on Hydatid Disease. Edited and arranged by Alfred Austin London, M.D. (Lond.) Sidney: L. Bruck. 1894.

On Amblyopia from Di-Nitrobenzol: with Remarks on the Employment of this Substance in the Making of Certain Explosives and its Effects on those engaged in the Manufacture. By Simeon Snell, F.R.C.S., Edin., etc. Reprint. 1894.

An Aid to Materia Medica. By Robert H. M. Dawbarn, M.D., Professor of Operative Surgery and Surgical Anatomy, New York Polyclinic. Third edition, revised and enlarged. By Woolsey Hopkins, M.D. New York: G. P. Putnam's Sons. 1894.

Rapports et Mémoires sur le Sauvage de l'Oveyron l'Idiotie et la Surdi-Mutité, par Itard avec une Appréciation de ces rapports par Delasiauve. Préface par Bournville, Eloge d'Itard par Bousquet avec portrait du Sauvage. Paris: Publications du Progrès Médical. 1894.

Address.

THE RISE AND FALL OF THE LICENSED PHYSICIAN IN MASSACHUSETTS, 1781-1860.¹

BY REGINALD H. FITZ, M.D., OF BOSTON.

GENTLEMEN:—In calling to order the Ninth Annual Meeting of our Association I desire to express the highest appreciation for the honor you have bestowed upon me in appointing me to preside over your proceedings. To conduct the affairs of so aristocratic a democracy has been made a task so easy that the gift of persuasion, or the knowledge of parliamentary law become wholly unnecessary qualifications. The one obligation which has weighed somewhat heavily is the thought of the opening address which is to prepare the way for such communications as you are to make for the advancement of scientific and practical medicine—all the more as my own attention has been particularly directed for the past few months toward a class of practitioners who have no idea of scientific medicine, and whose only thought of the practice of medicine is how much money can be made out of it. It may not be uninteresting to learn what men like yourselves, many years ago, did in order to discourage such persons—what they planned, what they accomplished, and why they failed. I will, therefore, ask your attention to the rise and fall of licensed physicians in Massachusetts, 1781-1860.

In the "Records of the Governor and Company of the Massachusetts Bay in New England" (1854, III, 153), is to be found the first legislation concerning the regulation of medical practice in Massachusetts. On the 3d of May, 1649, the General Court, held at Boston, voted as follows:

"Forasmuch as the lawe of God (Exod. 20:13) allowes no man to touch the life or limme of any pson except in a judicyall way, bee it hereby ordered and decreed, that no pson or psons whatsoever that are employed about the bodyes of men, woemen, and children for preservation of life or health, as phisitions, chirurgians, midwives, or others, shall presume to exercise or putt forth any act contrary to the knowne rules of arte, nor exercise any force, violence, or cruelty vpon or towards the bodyes of any, whether young or old,—no, not in the most difficult and desperate cases—with out the advice and consent of such as are skillfull in the same arte, if such may be had, or at least of the wisest and gravest then present, and consent of the patient or patients, (if they be mentis compotes,) much lesse contrary to such advice and consent, vpon such punishment as the nature of the fact may deserve; wch lawe is not intended to discourage any from a lawfull vse of their skill, but rather to encourage and direct them in the right vse thereof, and to inhibit and restrayne the presumptuous arrogance of such as through præfidence of their owne skill, or any other sinister respects, dare be bould to attempt to exercise any violence vpon or towards the bodies of young or old, to the prejudice or hazard of the life or limme of men, woemen, or children."

Until the years immediately preceding the War of the Revolution there was no more stringent regulation of medical practice than this. But in 1760 the City of New York had found it necessary to regulate the practice of medicine within its limits on account of the abundance of quacks preying upon the community. Five years later the Medical School of the University of Pennsylvania was established, and in the following year the New Jersey Medical Society was founded.

In still another year the Medical School of Columbia College began its career; and in 1771 the colony of New Jersey passed its act regulating the practice of medicine, to be followed in 1774 by the abortive attempt in Connecticut.

The years thus ripe in revolutionary ideas and acts produced their fruit in Massachusetts.

Although there were excellent physicians in the larger cities and towns of the Commonwealth, and several of them possessed medical degrees received in Europe, they were few and far between. Most practitioners had served merely a sort of apprenticeship to their seniors. There was no medical school in the State, and but two in the country, and these almost as remote as the leading schools of Europe at the present day. Any one undertook the study of medicine in such manner as he saw fit, and entered his practice with as little preparation as he chose. A considerable number of wholly unqualified practitioners thus were to be found, a source of danger to the community, a disgrace to the name of physician, and a cause of jealousy, contention and distrust, among the members of the profession.²

The example set by New Jersey and New York was one which demanded a speedy following, and thirty-one of the leading physicians of Massachusetts, sixteen being from towns outside of Boston, became incorporated as the Massachusetts Medical Society, "that a just discrimination should be made between such as are duly educated, and properly qualified for the duties of their profession, and those who may ignorantly and wickedly administer medicine whereby the health and lives of many valuable individuals may be endangered, or perhaps lost to the community."

That this purpose might be carried out, the President and Fellows of the Society or their appointees from its members were given "full power and authority to examine all candidates for the practice of physic and surgery, who shall offer themselves for examination, respecting their skill in their profession, and if upon such examination, the said candidates shall be found skilled in their profession, and fitted for the practice of it, they shall receive the approbation of the Society in letters testimonial of such examination," etc. They were obliged, under penalty, to hold this examination, although candidates were not obliged to present themselves for approval.

The State thus did not prevent the practice of medicine by any one, but it implied that the letters testimonial of the Society discriminated between the duly educated and properly qualified, and the ignorant and wicked. By the limitation of the maximum membership to seventy, admission to the fellowship became a proof of distinction which the better educated and higher minded physicians were proud to attain. This number, furthermore, gave evidence of the comparatively few physicians in the State at that time, who were considered worthy of this high distinction. Indeed, it repeatedly happened in the early life of the Society that it was impossible to secure the attendance of a sufficient number of Fellows to form a quorum to transact business.

Two years after the incorporation of the Medical Society the Medical School of Harvard College was established; and it was feared that the power of Harvard College to examine medical students and grant degrees in medicine might interfere with the authority

¹ The President's Address at the Ninth Annual Meeting of the Association of American Physicians held in Washington, May 29, 1894.

² Proceedings of the Massachusetts Medical Society, 1831, 19.

of the Society to examine candidates for practice and issue letters testimonial. According to the memorial of Dr. John Warren in 1811, this "would have produced the most unhappy effects, but for the repeal of an exceptionable article in that establishment, and the accommodating conduct of those who, at that time, were the guardians of science and the patrons of the healing art."³

But doubts arose with reference to the duties and powers of the Society concerning the examination of candidates and its authority to demand and receive compensation for its services and an act in addition to the act of incorporation was passed in 1789. It was therein made the duty of the Society, "in order more effectually to answer the designs of their institution, from time to time to describe and point out such a medical instruction, or education, as they shall judge requisite for candidates for the practice of physic and surgery, previous to their examination before them . . . and they shall cause the same to be published in three newspapers in three different counties within this Commonwealth."

The Society continued to fail in its object to create a proper standard of medical qualifications. The population of the State rapidly increased, and the number of practitioners likewise. There was no sufficient inducement to lead physicians to apply for the approval of the Society; and in the first twenty years of its existence only some twenty candidates had received the testimonials in approval of their professional skill.⁴ In the same period Harvard had conferred its medical degree upon thirty candidates.

Early in the present century Dr. John D. Treadwell, a young, learned, devoted and public-spirited physician of Salem, impressed with the inability of the Society to accomplish its aims, endeavored to improve its usefulness. An extensive correspondence was instituted among the members and with the assistance of Mr. Sewell, afterwards Chief Justice of the State, a bill was drafted, which, somewhat modified, was enacted in 1803.

The Massachusetts Medical Society, as it now exists, was then instituted; and its plan of organization became a model for other State Societies. It was no longer a close corporation with a limited membership, but it was possible for every physician in the State to become a Fellow. It was only necessary that he should have been a student in medicine agreeably to the regulations of the Society, and pass a satisfactory examination before the censors, after which he received a license to become a practitioner of medicine or surgery; "and after three years of approved practice in medicine and surgery, and being of good moral character, and not otherwise," he became a member of the corporation by subscribing to the by-laws.

The medical graduates of Harvard University were made licentiates without passing an examination, since the right to confer degrees had been granted Harvard College long before the Massachusetts Medical Society was incorporated. "The only means of avoiding collision with that ancient and respectable institution was by the compromise which was adopted."⁵

A duly licensed physician in Massachusetts in 1804 was required to give satisfactory evidence of the following qualifications before being admitted to exami-

nation for the license: Some acquaintance with Latin and Greek, and with the principles of geometry and natural philosophy; three full years of study under the direction of some respectable physician or physicians whose practice he must have attended. During this time he must have read the most approved authors in anatomy, physiology, chemistry, *materia medica*, surgery, and the theory and practice of physic. He was examined in physiology, pathology, therapeutics and surgery.

There was still no obligation on the part of any practitioner to present himself for license; and the only privilege enjoyed by the licensed physician, apart from the right to attend the meetings of the Society and the use of its libraries, was exemption from service in the militia.

Notwithstanding the Act of 1803 made it possible for every properly qualified physician to become licensed and a member of the Society, it proved necessary to take further steps to bring them within the fold, and in 1806 a by-law was passed in the following terms:

"To promote the laudable design of the Legislature, in forming and incorporating this Society, to prevent as far as may be all unqualified persons from practising medicine or surgery, and in order to discourage empiricism and quackery: it shall be deemed disreputable and shall be unlawful, for any fellow of this Society, in the capacity of physician or surgeon to advise or consult with any person, who having been a fellow of the Society, shall be expelled therefrom, or with any person whatever, who shall thereafter commence the practice of medicine or surgery within this Commonwealth, until he shall have been duly examined and approved by the censors of the Society or by those of some district society," etc.

The object of this by-law was to guard the public against ignorant, designing and unscrupulous pretenders. The Society had provided the means by which physicians could give evidence of having followed a suitable course of study, and it was its duty to inform the public that if it employed unlicensed practitioners it must suffer the consequences.

Notwithstanding these attempts at compelling practitioners to become educated physicians, the standard was evidently too high for all to attain. Many could not comply with the requirements; others did not find a sufficient inducement in the honors and privileges bestowed by the Society. The Thomsonians, then beginning their career, required no education and no license. There was no law to prevent their entering practice; and Chief Justice Parsons⁶ had then made his famous decision in the case of the Commonwealth v. Thomson, "that if the prisoner acted with an honest intention and expectation of curing the deceased by this treatment, although death, unexpected by him, was the consequence, he was not guilty of manslaughter. . . . There is no law which prohibits any man from prescribing for a sick person with his consent if he honestly intends to cure him by his prescription; and it is not felony, if through his ignorance of the quality of the medicine prescribed or of the nature of the disease or of both, the patient, contrary to his expectation, should die."

The Chief Justice evidently felt that there was likely to be need of some legislation which should prevent the occurrence of such cases, for he closes his decision by saying: "It is to be exceedingly lamented

³ Dr. S. A. Green's Centennial Address, Med. Comm. Massachusetts Medical Society, 1876-81, xii, 639, 604.

⁴ Dr. James Jackson's Speech at the Annual Dinner, 1856.

⁵ Proceedings Massachusetts Medical Society, 1831, 26.

⁶ Massachusetts Reports, 1809, vi, 124.

⁷ Loc. cit., p. 142.

that people are so easily persuaded to put confidence in these itinerant quacks, and to trust their lives to strangers without knowledge or experience. If this astonishing infatuation should continue, and men are found to yield to the impudent pretensions of ignorant empiricism, there seems to be no adequate remedy by a criminal prosecution, without the interference of the legislature, if the quack however weak and presumptuous, should prescribe, with honest intentions and expectations of relieving his patients."

In 1811 an unsuccessful attempt was made to incorporate a rival society with the same privileges as those enjoyed by the Massachusetts Medical Society, under the title of the Massachusetts College of Physicians. The announced reason was that two Societies were better than one; the real object was thought to be the establishment of a new medical school.

The Massachusetts Medical Society strongly opposed the scheme, on the ground that it was unnecessary and would lead to the rejected candidates of the one society being accepted by the other, whatever might be their qualification, thus producing disagreements and animosities injurious to the profession and to the public.⁸

It is possible that in consequence of the recommendation of Chief Justice Parsons, certainly with the view of discouraging quackery which was rapidly increasing under the influence of Thomson, the legislature in 1818 passed its first "Act regulating the Practice of Physick and Surgery," which was supplemented in 1819 by "an Act in addition to an Act entitled 'an Act regulating the practice of Physick and Surgery.'"

According to the first of these acts, no person entering the practice of physic and surgery within the State could recover by law any debt or fees for his professional services unless he had received a medical degree from some college or university or had been duly licensed by some medical society or college of physicians or by three Fellows of the Massachusetts Medical Society, designated in each county by its councillors, with power to examine candidates and grant licenses. Copies of these licenses were to be deposited with the clerk of the town, district or plantation in which the licentiate resided.

In the Act of 1819, that the physician might recover his debts by law, it was necessary that he should be a licentiate of the Society or a Medical Graduate of Harvard. If the candidate for the license was educated out of the State, the censors might waive a new examination if they were satisfied that he had received an education agreeably to the regulations provided by the Society.

It is stated⁹ that this difficult trust was accepted with reluctance,¹⁰ that the law was not sought for by the Society, and that it was doubtful whether its action was not rather injurious than beneficial. Of this law Chief Justice Shaw said:¹¹

"It appears to us that the leading and sole purpose of this act was to guard the public against ignorance, negligence and carelessness in the members of one of the most useful professions, and that the means were intended to be adapted to that object. If the power of licensing were given to the Medical Society exclusively, there would be much more plausible ground, at least, to maintain that the power was conferred on a body who would have a temptation to abuse it, so as

to promote their private interests; but where the power is conferred equally on the university charged with the great interests both of general and professional education, and which cannot be perceived to have any such interest, that ground of argument seems to be wholly removed, and it seems difficult to perceive how a power which it is important to the community should be placed somewhere could be placed more safely. The courts are all of the opinion that the law in question is not repugnant to the Article of the Bill of Rights, above cited, and that its validity cannot be impeached on the ground that it is a violation of any principle of the constitution."

The licensing of physicians by the Society doubtless aided in restraining a certain number of practitioners from adopting some of the methods of the charlatan; but it did not interfere with the encouragement of the latter by the community. I am indebted to Dr. John Homans, 2nd, for the opportunity of quoting from a letter of Dr. George C. Shattuck to Dr. Homans, written July 26, 1828. It gives evidence of the fondness for quackery in Boston at that time.

"The city has 60,000 (inhabitants?) and seventy-one regularly bred physicians. About one-half, from either youth or age, have not much to do. The irregular physicians are numerous, at the head of which, in popular influence, we may place Thomson, who has formed his botanical society, who have individually learned his system of practice by hot drops and sweating, etc. The disciples of this system, perhaps, may embrace one-sixth of the population of Boston. The patent medicines are employed in about, I believe, another sixth of the cases."

In 1831 the Society had reached such a degree of success in carrying out the objects of its incorporation that it included in its ranks "nearly every educated practitioner of medicine or surgery in the State."¹²

The line of distinction was so strongly drawn between its members and irregular practitioners "that the profession is no longer made responsible in the minds of men for the consequences of their ignorance and malpractice, nor its harmony disturbed by their misconduct; and they are much less successful than formerly in diverting the confidence of the community from regular physicians to themselves."¹³

At this time, however, there were certain discordant elements within the Society which threatened its prosperity and usefulness. Some of the younger physicians were dissatisfied with the clause in the act of 1803, which demanded a period of three years of probation in practice before admission to full membership in the Society. The legislature was therefore requested to repeal this clause, which it did by a special act in 1831, and approved candidates became at once Fellows of the Society.

A more serious disturbance, which menaced the harmony and influence of the Society at this time, was the appeal to the legislature from the physicians of Berkshire County, in the western part of the State. They desired to be incorporated as an independent body, nominally on account of their distance from the headquarters of the Society, their limited privileges, and their dissatisfaction with the requirements of the censors. It was supposed that this action was largely planned in the interests of the Berkshire Medical Institution, a medical school incorporated in 1823, but without the authority to confer the degree

of Doctor of Medicine.¹⁴ It was situated in Pittsfield, and was practically a department of Williams College (not far distant), which had the power to confer degrees, but no medical faculty or medical school. Williams College sanctioned the degree of the candidates educated at the Berkshire Medical Institution. The conditions of this alliance proved important in the courts¹⁵ when the honorary degree of M.D. from Williams College was offered in evidence as a legal qualification. It was decided that it was invalid, since the defendant must have both the education and the degree to be a legally qualified practitioner.

In the year following the incorporation of the Berkshire Institution it had petitioned the legislature to be granted the same privileges as belonged to the medical graduates of Harvard University, the most important of which was that of being acknowledged and received by the Massachusetts Medical Society without examination as regular practitioners of medicine and surgery.

At that time this petition was successfully opposed, on the ground that the Berkshire Institution had no independent board of overseers like Harvard College, and therefore was not under the same restrictions and oversight. The petition to form an independent society was also successfully opposed; but in 1837, with the approval of the Society, an act was passed, according to which graduates of the Berkshire Medical Institution were "entitled to all the rights, privileges and immunities granted to the medical graduates of Harvard College."

The rights and privileges of the licentiates of the Massachusetts Medical Society had been somewhat extended by the Anatomical Law of 1834, according to which "the dead bodies of such persons as it may be required to bury at the public expense might be surrendered to any regular physician duly licensed according to the laws of this Commonwealth."

The State had thus definitely committed itself to the regulation of the practice of medicine by the Acts of 1818 and 1819, and had placed the duty of licensing practitioners in the hands of the Massachusetts Medical Society. It conferred but few privileges on the licensed, namely, exemption from militia service and jury duty, the right to obtain and dissect the unclaimed bodies of those to be buried at the public expense, and to collect fees by law.

But unlicensed physicians could take their pay in advance, and were not desirous of the privilege of consulting with the members of the Society. The Thomsonian movement was rapidly spreading throughout the country, appealing to the people by its simplicity and economy, its dogmatic assertions and reports of wonderful cures, its advocacy of vegetable remedies, and its cry of persecution.

The efforts of the Society to include within its ranks all educated practitioners, led in 1836 to the recognition of dentists as practitioners of medicine, since dental surgery was being studied and pursued scientifically by gentlemen of regular medical education.¹⁶

In the following year a further attempt was made in this direction by requiring that every licentiate or medical graduate of Harvard or Berkshire entitled to admission to the Society must enter within a year after being so entitled or be deemed an irregular practitioner.

This term was applied to all practitioners in the State who were not fellows or licentiates of the Society, or doctors in medicine of Harvard or Berkshire. The above regulation was repealed three years later, since it took away "the freedom originally intended to be allowed to all regular physicians to join the Society or not, as they pleased," and stigmatized "as irregular practitioners gentlemen who have been recognized as competent physicians merely for the exercise of this freedom."¹⁷

In 1836, the Statutes of the Commonwealth were revised, and the report of the commissioners (1835, Part I, 125) includes all the legislation previously enacted, placing the control of the licensing of physicians in the power of the Society.

But the legislature did not accept the first section, which read as follows:

"No person who has commenced the practice of physic or surgery, since the year one thousand eight hundred and eighteen, or who shall hereafter commence the practice thereof, shall be entitled to maintain any action for the recovery of any debt or fee accruing for his professional services, unless he shall, previously to rendering these services, have been licensed by the officers of the Massachusetts Medical Society, as hereafter provided, or shall have been graduated a doctor in medicine in Harvard University, or in the Berkshire Medical Institution, by the authority of Williams College."

It also negated a clause making the neglect to record a license a like disqualification to its non-possession.

The legislature approved this part of the report of the committee with the above exceptions, and it became Chapter 22 of the Revised Statutes entitled "Regulations Concerning the Practice of Physic and Surgery."

According to Dr. J. Mason Warren¹⁸ the first section was omitted in accordance with the wishes of the greater part of the (State Medical) Society, as being in its action adverse to their interests. It served merely to excite sympathy, especially for the Thomsonians, and could not prevent them from receiving fees for services rendered.

The Society continued in its work of licensing physicians without apparent disturbance until 1848. At this time its effect in controlling the conditions of medical practice in the State is thus expressed by Dr. A. L. Peirson, of Salem, in behalf of a committee of which he was chairman:¹⁹

"We have steadily elevated our profession, by improving medical education, encouraging the harmony and honorable intercourse of its members, and have protected from the mischief of quackery, by discouraging every show of it among regular practitioners. This simple and efficient plan of the Society has accomplished all that was ever intended by its organization in 1803. . . . It is to be regretted that from natural causes, no way to be attributed to the form of organization, the concentrated action of the Society has not been equally felt in all parts of this extended Commonwealth."

According to Dr. Z. B. Adams,²⁰ there were at this time 1,237 medical practitioners in Massachusetts, most of whom belonged to the Massachusetts Medical Society.

On the contrary, Dr. J. V. C. Smith presented the

minority report of the same committee, in which he states :²¹

"The Society was once eminently useful in protecting the community from the encroachment of ignorant pretenders, . . . and it must be obvious to all that circumstances have greatly changed, our legislative tables have been completely turned, and will probably ever remain so. A license, or medical degree, is no longer requisite for the practice of medicine in Massachusetts, and no laws of the State, or of the Massachusetts Medical Society, are of any avail in guarding the entrance into the profession, or regulating the conduct of its members. . . . Less than one-half of the regular practitioners of medicine now nominally constitute the Society. In Berkshire, there are one hundred; less than twenty belong to the Society. In Hampden, one hundred and thirty (about); and of this number only about twenty or twenty-five are members of the State Society. In some other counties there is doubtless a majority, while in others not one-half of the regular physicians are members. The number of Fellows of the Massachusetts Medical Society is not far from seven hundred, which is not probably one-half of the physicians in the State."

These reports were called forth by a resolution presented by Dr. Childs, of Pittsfield, involving a change in the organization of the Society for the purpose of advancing medical science, promoting harmony and good feeling in the profession, thereby contributing to the best interests of society.

Although the councillors largely favored the views expressed in the majority report, the existence of a considerable degree of dissatisfaction and the necessity of remedying it was apparent in the appointment of a committee to consider the question of altering the by-laws. This committee consisted of Drs. John Ware, A. L. Peirson, W. Lewis, J. Jeffries, J. V. C. Smith, H. H. Childs and John C. Dalton. The report of this committee is especially valuable from the character of the latter and the recognition of the necessity of the Society to increase and consolidate its strength.

They found²² that many members had often expressed the opinion that the Society as constituted did not accomplish all of the purposes of which it was capable—and failed to secure the favor of the profession in remote parts of the State. Consequently only a limited number of physicians found it for their interest to become members. They were called upon to obey laws which they had no voice in making and to contribute to the expenses of an organization in which they found it difficult to take part. The Society was but little known to those among whom they are thrown, thus has but little influence over them, and it was not necessary to their reputable standing among physicians nor to their success with the community that they should be connected with it.

The committee reported various amendments to the by-laws involving favorable action of the legislature which took place in 1850. By-law V permitted any reputable practitioner of medicine or surgery who had been in practice not less than fifteen years, to be admitted a Fellow, previously to 1852, by the District Society where he resides by a vote of two-thirds of the members present at any stated meeting.

The Society was thus endeavoring to increase its influence in the one direction by licensing as many educated and intelligent physicians as possible, and even without examination in certain instances.

This liberality, however, was to be controlled by

what many now see to have been an unwise policy, namely, the treatment of the homœopathists.

In 1846²³ an applicant for membership stated that he had great confidence in the efficacy of medicine "especially when prepared and prescribed agreeably to the directions of Hahneman." The councillors referred the application to the censors, with full powers to settle the matter, and they admitted the applicant to membership.

In the meantime the influence of homœopathy was increasing, and in 1850²⁴ it was moved "that all homœopathic practitioners are, or should be, denominated irregular practitioners, and, according to the By-Laws of this Society, made and provided, ought to be expelled from membership." This resolve was tabled on motion of Dr. Bigelow.

At the next meeting, Drs. Hayward, O. W. Holmes and J. B. S. Jackson were appointed a committee "to devise some course of action, to be pursued by the Society, in regard to all homœopathists." This committee reported as follows :²⁵

"(1) *Resolved*, That any Fellow of this Society who makes application to resign his Fellowship in consequence of having adopted the principles and practice of homœopathy may be permitted to do so on paying his arrearsages; but he shall not be entitled to any of the privileges of Fellowship, nor shall his name be retained in the list of Fellows.

"(2) *Resolved*, That a diploma from a homœopathic institution shall not be received as any evidence of a medical education; nor shall the Censors of the Society regard the attendance on the lectures of such institutions, nor the time passed at them, as qualifications which shall entitle candidates to an examination for a license from this Society."

This report was adopted. Three years later the question of homœopathy was again brought before the Society at the annual meeting.²⁶ The Essex North District Society there presented the following resolution :

"Forasmuch as there is no common ground of support or sympathy between homœopathy and allopathy;

"*Resolved*, That if the homœopathists are allowed to retain their regular standing in the Massachusetts Medical Society, and claim fellowship and counsel with allopaths, we, as consistent and conscientious individuals, request to be honorably discharged from our allegiance and connection with the parent society."

Dr. Spofford presented the following resolution :

"That, while we recognize the right of regular physicians to use medicine in any quantity or doses which they may consider useful to their patients, we consider all use of the name of homœopathy in public papers, on signs or otherwise, as quackish and disreputable, and that all persons who make pretensions to homœopathic practice ought to be excluded from the Society."

These resolutions, together with the whole subject, were referred to the councillors, who appointed the following committee to report upon them: Drs. Bigelow, Metcalf, M. Wyman, Spofford and Alden. Dr. Jacob Bigelow reported in February, 1854, and his report was laid on the table.

In the next year,²⁷ the censors of the Suffolk District Society rejected a candidate for admission who avowed himself practising upon the principles styled

homœopathy, on the ground that he was not "fitted for the practice of medicine." It was voted (February 7, 1855), on motion of Dr. Bowditch, "that the Councillors approve of the course adopted by the Censors of the Massachusetts Medical Society for Suffolk District."

In the following June this district society called the attention of the general society to defects in the by-laws concerning the expulsion of members, with reference to a remedy; and this question, together with that concerning the admission of members, was referred to a committee for a report. A few days later the latter reported. Their report was referred to the councillors for adoption. They, in turn, referred the report to a committee, which altered the recommendations; these were adopted by the councillors in February, 1856, and by the Society on May 29, 1856.

These alterations made it possible to expel a member for any breach of the by-laws, for which censure, expulsion or deprivation of privilege was a penalty, and for any conduct unbecoming and unworthy an honorable physician and member of the Society, in addition to causes hitherto deemed sufficient. A carefully arranged method of conducting trials for offences was also provided. The report of the committee of the councillors recommending these alterations stated that they had no definite measures to offer with regard to homœopathy, and submitted the subject to the judgment of the councillors. This part of the report was laid on the table without debate.²²

June 3, 1856, four days after the adoption of the amended report by the Society, the Homœopathic Medical Society was incorporated by the legislature. It was authorized to examine all candidates for membership, and, if qualified, give them the approbation of the Society. Its members were declared exempt from militia service.

In the following year, the motion that all candidates for the fellowship be examined by the censors was referred to a committee, reported upon favorably, and the legislature passed a special act March 5, 1859, making this method the law.

At this time the revision of the statutes was again under consideration, and the commissioners had made their report to the legislature, in which the existing laws concerning the regulation of the practice of medicine were included. This report was referred to a joint committee, which was subdivided into special committees. The general committee referred the chapter concerning the regulation of medical practice to one of these special committees on May 16, 1859. It instructed this committee, "by special order, to inquire into the expediency of omitting all that part of the chapter relating to the Massachusetts Medical Society and to the regulation of the practice of medicine; and on the 21st of May they reported to the general committee amendments striking out every section, and every line, and every word in that chapter which gave the Massachusetts Medical Society any power to examine or license physicians or surgeons, or to prescribe a course of study and qualifications for physicians or surgeons."²³

Four days later, the councillors appointed a committee, consisting of Drs. J. Bigelow, A. A. Gould, J. Jeffries, G. C. Shattuck, H. J. Bigelow, H. H. Childs

and J. G. Metcalf, and "instructed them to look after the interests of the Society in the legislature," and they were "authorized to take such measures to protect their interests as they may deem expedient."²⁴

But, in the words of Mr. Benton, "The general committee adopted these proposed amendments, with the addition of a change of title of the act from 'Regulations concerning the Practice of Physic and Surgery' to 'of the Promotion of Anatomical Science'; and that chapter now stands, with the same title as Chapter 81 of the Public Statutes. All the amendments were adopted by the legislature, and were enacted December 28, 1859. . . . The legislature then deliberately took out of the law of the Commonwealth every provision for the regulation of the practice of medicine or surgery, or for the examination or qualification of physicians or surgeons."

The committee of the Society appointed to look after its interests in the legislature recommended, October 5, 1859, that "no person shall hereafter be admitted a member of the Society who professes to cure diseases by Spiritualism, Homœopathy or Thomsonianism," which was adopted. As evidence of the state of feeling at the time, it may be said that at the meeting at which this resolution was approved, it was voted that the Society disclaim all responsibility for the sentiments contained in the annual address of the day previous. This had been delivered by Oliver Wendell Holmes, and was entitled, "Currents and Counter-Currents of Medical Science."

Thus we see that the Massachusetts Medical Society was organized in 1781 with the express purpose of making a just discrimination between duly educated and properly qualified practitioners and those who ignorantly and wickedly administer medicine. For many years its Fellows acted most judiciously in endeavoring to include within their number every educated and moral practitioner in the State. They accomplished this largely by the force of example, association and united encouragement. The State made them the sole source of licenses to practise. The progress of Thomsonianism left their responsibilities essentially intact. The advent of homœopathy found them weak where they should have been strong, short-sighted where they should have been far-seeing. The leaders were obliged to follow, and the reproval of the censors prevailed against the wisdom of the councillors.

Homœopathic diplomas and homœopathic certificates are now accepted by the Society. Homœopathic physicians have been found fitted to practise by the great public, which decides this question for all. Ten years of increasing intolerance destroyed seventy years of enthusiastic effort, devoted labor, tactful management and wise council in the public interest. The State revoked the control of medical practice, and the people have been the sufferers. The history of Massachusetts in this respect is the history of the country. She was one of the last of the States to lay down the control, and she will be one of the last to resume it.

Thanking you for the patience with which you have listened to an historical narrative which offers but little in the way of moral or example to our own Association, we will proceed to the business of the day.

MRS. HUMPHREY WARD, the novelist, is said to be suffering from writer's cramp.

METHODS OF TEACHING SURGERY.¹

BY JOHN S. BILLINGS, M.D., SURGEON UNITED STATES ARMY.

THIS paper has been prepared at the request of the Committee on Programme, to serve as an introduction to a discussion upon the best methods of teaching surgery, and is intended to ask questions rather than to answer them. We have to consider: (1) Who are to be taught? (2) What is to be taught? (3) How it is to be taught.

Those who are to be taught include two classes: (1) The average medical student, who is presumably to become a general practitioner; (2) The men who wish to specially fit themselves for surgical work. There is a third class, namely, those who wish to learn only the least possible amount of surgery which will enable them to get the degree of M.D., but these we need not consider to-day.

The surgical instruction to be given the average student depends on what he is required to know of anatomy and pathology before he begins his surgical studies, upon the amount of time which is allowed for surgical instruction, and upon the nature of the final examination which he must pass to obtain his degree, or license to practice.

In any case it should include the diagnosis, and best method of treatment, of the injuries and surgical diseases which the general practitioner is most often called upon to treat, including recent wounds and their complications, erysipelas, abscess, ulcers, etc.; fractures and dislocations, injuries of blood-vessels, strangulated hernia, urethral stricture, retention of urine and its consequences; obstruction of, or foreign bodies in, the air passages; and also the selection and administration of anesthetics, the details of aseptic and antiseptic methods, and of methods of performing the most usual amputations and ligations of blood-vessels.

Let us suppose that the instruction is to be given in a three-years' graded course; what other subjects besides those above mentioned ought to be fully treated of by the surgical teacher? Under such circumstances is it worth while to go into the details of cerebral and abdominal surgery, of lithotomy and lithotripsy, of excisions of organs or of the jaws and joints, of plastic and orthopædic surgery? Is it not enough to tell the average student what can be done in these directions, and refer him to special courses or to current literature for further information with regard to complicated and difficult operations requiring special instruments and apparatus? Of course, it is to be practically demonstrated that the teacher is the proper person to whom cases of this kind should be sent.

Deferring for a moment the consideration of the needs of the man who wishes to become a surgeon, we come to the question, "How are these subjects to be taught?" There are five principal methods: (1) Didactic systematic lectures; (2) recitations; (3) demonstrations and practical instruction by means of manikins, dummies, cadavers, and operations on animals, in the details of treatment of wounds, bandaging, dressings and operations; (4) theoretical clinical lectures, in which cases and operations are shown in an amphitheatre; (5) practical clinical instruction to small groups of students or ward classes, in which, as

far as possible, each student has something to do in the diagnosis or treatment or both.

The modern tendency is to reduce the time given to systematic lectures. In discussing the wisdom of this, we must bear in mind the different organization of the teaching staff in different schools, the increasing number of chairs or lectureships devoted to specialties, and the fact that the precise division of subjects among the instructors in a given school must depend to a considerable extent on local conditions, on the character, tastes and teaching-powers of the different men who make up the faculty, on the amount and character of the facilities for laboratory and clinical teaching present, etc.

In the old-fashioned type of medical school, in which the whole instruction was given by seven or eight men, the professor of surgery taught what was called surgical pathology, or the principles of surgery, gave considerable attention to surgical anatomy, and was the clinical as well as the systematic teacher. There was at least one advantage, namely, that the teaching was consistent and harmonious; the student was not much bewildered with the conflicting views of different professors. The professor of anatomy was in training for the chair of surgery and took very little interest in comparative anatomy or in embryology. There was no professor of pathology; and both the professor of surgery and of medicine lectured on inflammation, congestion, suppuration, etc., each from his own point of view.

At present, in a large and popular medical school, there are from twenty to thirty teachers of various grades; there is a professor of pathology, of surgery, of clinical surgery, of surgical anatomy, of orthopædic surgery, of genito-urinary surgery, etc., and the professor of gynecology takes a large share of the abdominal surgery.

Now how can the subject of surgery be subdivided among all these teachers in such a way that the whole field shall be covered, without involving useless repetitions, embarrassing contradictions, and the expenditure of an undue amount of time and labor by the student, or of the production of heart-burnings in some of the teachers? This is one of the most difficult problems in the organization of a large medical school which is to be really efficient and popular, and it is one to which no general and universal formula is applicable.

Theoretically, each professor being a thoroughly wise, unselfish, good-tempered man, desiring only the best interests of his pupils and of his school, and there being frequent consultations between them to secure harmony in their teachings, the desired result may be obtained. Practically there are usually two or three strong men in the faculty who settle what shall be done, and the rest find it expedient to submit, although they may not agree. When there are no sufficiently strong men, and all the professors are not perfectly good and unselfish, there may be trouble.

Let us consider details a little. A well organized medical school should have a professor of pathology and pathological anatomy, under whose direction a certain amount of laboratory instruction should be given — comparatively simple for the average student, extended and elaborate for post-graduates. The greater part of his teaching for the average undergraduate student must be by lectures, with demonstrations.

Given such a teacher, with the necessary facilities, why should the professor of surgery lecture on surgi-

¹ Paper read before the American Surgical Association at Washington, Wednesday, May 30, 1894.

cal pathology or bacteriology to the average undergraduate? The only really good reason I think of is, that he should be thoroughly familiar with the subject, and at times use experimental methods in devising improvements in surgical practice, and that teaching the subject greatly helps him to obtain, classify and retain his knowledge. But his teaching on this subject would be most valuable to a special class of advanced students, or post-graduates — who can devote themselves to it, and give the necessary time to that experimental work on animals which is absolutely essential to secure satisfactory results.

At all events, I think we can agree that the relations between the surgeon and the pathologist should be intimate and friendly, while each should be entirely independent of the other, and that the surgeon should go into details of practical application of principles in accordance with the more general teaching of the pathologist.

As regards the teaching of surgical anatomy, and of operations on the cadaver, by a teacher distinct from, and entirely independent of, the professor of anatomy on the one hand and the professor of surgery on the other, I believe that there are widely different opinions as to its expediency. Such an independent chair, or demonstratorship, is usually provided to make a place for some particular man, and its utility must depend upon who this man is.

While no general rule on this point can be laid down, might it not be best that attendance on such an independent course should be purely voluntary on the part of the class, and that it should be largely devoted to the instruction of those who wish to make a specialty of surgery? It appears to me that more use should be made of living animals than is now done, in teaching the results and treatment of wounds, including details of asepsis and antiseptics, and in special courses for advanced students who should be required to perform operations under the guidance of the surgeon.

The next question is as to the part which clinical surgery should play in a course of education leading to a medical degree. The great majority of students prefer clinical teaching and demonstrations to didactic lectures, and will go where this clinical teaching is most brilliant and varied; and, so far as it goes, we must admit that this kind of teaching is generally the most useful to them, because they remember it better. How far is it possible to cover the field of diagnosis and treatment of injuries and surgical diseases by clinical teaching alone to the extent that it is desirable for the average medical student? And how far is it desirable to vary and modify the didactic teaching so as to make it supplementary to the clinical teaching?

Evidently the answers to these questions must depend in part upon the amount and variety of clinical material that is available, and hence must differ for different schools. As a rule, clinical material is not available to cover the entire field for any school, no matter how large its hospital and dispensaries — hence there must be some systematic didactic teaching. Is it best that this should be a complete independent course covering the whole field, merely using for any particular subject such cases as may happen on that day to be available, thus leaving the greater part of the clinical teaching to duplicate that which has been given in the systematic course? This is, upon the whole, the easiest way, and in favor of it is urged that it is desirable that the student should be told the same thing

several times to ensure his remembering it. This is the argument which used to be used in favor of the old plan of not having a graded course but compelling the students to listen to the same course of lectures in successive years.

On the other hand, it can be seen that there would be certain advantages in deferring the systematic lectures until towards the end of the course, and then devoting them mainly to subjects which had not been illustrated in previous clinical teaching; but to make this plan a success it would be necessary that the systematic lecturer should either have given all the clinical instruction, or should be perfectly familiar with all that has been given.

A possible modification of this plan would be to let two professors divide the field of work, each taking a certain class of diseases and injuries, giving clinical instruction thereon and supplementing it with systematic teaching as above suggested, and then the two men exchanging fields of work each year. An objection to this is that a considerable part of clinical teaching is given in connection with patients who select their own surgeon, and who will not make such selection with reference to any curriculum. Undoubtedly the more clinical instruction of the right kind that can be given, the better for the students, and for the reputation and prosperity of the school.

But this phrase "clinical instruction of the right kind" brings up a new set of questions. How much does it profit the student to witness, from the rear benches of an amphitheatre, such operations as the ligation of arteries, the extirpation of tumors, lithotomy or nephrectomy? Undoubtedly the student is interested and learns something, and he will go where he can see — if not the operation itself, at least the heads of the persons who are busy about the patient; and it will not do to restrict his privileges much in this respect. At the same time, should not special opportunities be given to the few who are devoting themselves specially to surgery to see as much as possible of difficult and unusual operations? It appears to me that more than two hundred men cannot possibly obtain any special information from surgical clinics in an amphitheatre which they could not obtain equally well in a didactic lecture, and which could not be much better given with illustrations by means of lantern slides, than by using a patient as a means of demonstrating an operation. It is quite possible to show by means of lantern slides, as Dr. Kelly has proved, to several hundred men, every detail of an operation which can be seen by the immediate assistants of the operator.

Now with regard to clinical teaching to comparatively small sections, or ward classes, the members of which are to be brought as much as possible into contact with the patient, and even to assist in the operation of dressing. There is no doubt as to the utility and popularity of this mode of teaching, but in this connection a word may be said with regard to the relations of hospitals and dispensaries to surgical teaching.

While I believe that a hospital is not doing its fullest and best work if it is not increasing and diffusing knowledge, and that patients secure the best and most careful attention and treatment in teaching-hospitals, where the work of the staff is keenly scrutinized, yet it must be admitted that there is sometimes a danger that people will get the idea that in a teaching-hospital the interests of the patients are not as fully consulted

as they should be, and will avoid that hospital as much as possible. This danger arises mainly from two things: first, the allowing students to have anything to do with the treatment, and especially with an operation. The patient wants to be operated on by the most skilled man, that is, by the professor; and if he has a suspicion that after he is under the influence of an anæsthetic the professor may hand the knife to a student to make perhaps his first essay, he will avoid that place. All of us would do the same, and therefore in ward-class teaching a patient should never be deceived as to who is to perform the operation, for sooner or later the deception will be discovered and the news will spread.

The second danger to the popularity of a teaching-hospital is that patients are not unfrequently made to wait until their cases can be used for clinical instruction, sometimes for hours, sometimes for days. In most cases the patient knows when he is to be put off for this purpose, and after one experience of the kind he will go to another hospital the next time and advise his friends to do the same.

It is well also that the clinical surgical teacher should remember that his ability to obtain abundant clinical material depends to a very considerable extent upon the manners and on the good-will of some of his assistants, the resident physician, the nurses, etc., who are often the first to see the patient as an applicant, and who have much to do with subsequent treatment.

These assistants, residents, receiving-officers, case-takers and nurses, are not always possessed of the exquisite tact, kindly sympathy, and knowledge of human nature which it is to be presumed are invariably the characteristics of the clinical surgeon; and it is a part of his business to instruct them and perfect their manners as much as possible.

Recitations and quizzes are excellent methods of teaching for the majority of students, but are only well adapted to small classes or sections. At present they are, for the most part, conducted as a private enterprise by persons who may, or may not, be on the teaching staff. The question as to whether this mode of teaching should be made use of in the official course to a considerably greater extent than is now done is an interesting one and is commended for discussion. It appears to me more desirable that it should be applied to the clinical teaching than to the didactic lectures, and one good result of this would be to discourage the reliance on quiz compends, which I think invariably do more harm than good.

With regard to modes of lecturing, every man is, of course, a law unto himself; yet I will venture one or two suggestions. The teaching for a class of students should be definite, selective, and, to a considerable extent, dogmatic; and critical historical discussions should be used very sparingly.

What the student hears and sees during the first half-hour of a lecture is what he will remember best, and will have the best notes of; therefore, when there are several different ways of doing a thing, let the teacher describe first the method which he prefers, taking all the time required to fully demonstrate it and impress it on the student. After that is done the other methods may be referred to and so much history and criticism given as time will permit. If the reasoning is given before the conclusions are stated, the student is apt to get confused, and to characterize the teacher as a "wobbler."

If the lecturer will fix in his mind the half-dozen questions or so that he would ask to test the students' knowledge of the subject upon which he is going to speak, and will then make it his main object to answer those questions clearly, definitely and fully, he can hardly fail to give a good lecture.

In objecting to too much history in didactic or clinical lectures on surgery, I do not wish to be understood as underestimating the importance of giving historical instruction. I think that in every medical school a course of lectures on the history of medicine and surgery, combined with practical instruction in bibliographical methods, should be given; and if this is not done, then I would advise that the professor of surgery devote five or six lectures to the history and literature of his subject, which lectures will probably be most useful and interesting at the beginning of the last year of the student's course.

It was stated at the beginning of this paper that besides the average medical students, the needs of the man who wishes to specially fit himself to be a surgeon should be considered. These relate to post-graduate work mainly, for a broad foundation of medical knowledge is requisite for the man who wishes to become a surgeon. The technique of operative surgery, important as it is, is secondary in importance to skill in diagnosis, and to knowledge of therapeutical methods which do not involve the use of the knife.

The man who intends to be a surgeon should not only make a special study of surgical anatomy, but should do a considerable amount of practical laboratory work in bacteriology, pathological histology and experimental pathology and physiology.

It is quite true that the majority of our leading surgeons could not perhaps, by themselves, make a bacteriological diagnosis, or determine fine distinctions in new growths, and yet they do good work — having these points settled for them by younger men trained in the new methods. But the surgeon of the future should himself be trained in these methods, even though he may employ others to carry them out.

And in this connection I would remind you that bacteriology cannot be profitably studied for two or three days in a week, but that it needs at least three hours a day every day for three months for a man to learn how to begin readily to use its methods. In general, I think that all studies are best concentrated, and that the usual plan of dividing studies into an hour two days a week for this, and an hour three days a week for that, etc., is much more for the convenience of the professors than it is for the true interest of the students.

As for operating technique, much of it can be learned on animals, but much of it requires also work on the cadaver, the repetition over and over again, until, as Billroth said, a man could do it when he was asleep. The most important of all is residence in a hospital, the working as assistant to a surgeon, the seeing and handling cases, and not merely looking at them from a distance. The number of men who are able and willing to carry out such a course of study as that indicated is limited, and the teacher of surgery cannot do very much for them except give them opportunities for seeing his methods and results; but is it not possible to give them better opportunities than can be provided for a large class of undergraduates? Should they not be required to repeatedly perform the many operations which can be advantageously performed on animals

before they try these operations on man? It seems to me that in the last year of a four-years' course all students should be tested in this way; but it must be admitted that, with the present curriculum, there is not time to spare for this purpose, especially where the graduating class is a large one.

This leads to two final questions, which, though not directly connected with "the best methods of teaching surgery," have nevertheless, an important bearing on it. The first is: Are there not some subjects which occupy too much space in the undergraduate curriculum of our largest and best medical schools, such for example, as inorganic chemistry, and embryology? Ought not the student to be required to know so much as is required of inorganic chemistry before he begins his medical course? Is it desirable to make embryology and general morphology a part of the curriculum for all medical students, as a basis for the study of anatomy, or is it wiser to place these as elective studies in a post-graduate course, and to insist on more dissecting and a greater knowledge of practical anatomy than is now generally demanded? In this connection your attention is invited to the widely different opinions as to the best methods of anatomical teaching — as represented by Professor Macalister for the morphologists, and Mr. T. Cooke for the old school, which have appeared in the *Lancet* and in the *British Medical Journal* during the past year.

It appears to me that the teaching of anatomy should begin with a few lectures and demonstrations on general morphology, and that the first dissections should be made on cats and dogs until a good technique has been acquired, so that the supply of human cadavers, which is always insufficient, can be fully utilized to the best advantage. I also think that it is unwise to have the final examination in anatomy one or two years before the other final examinations; the anatomy should be kept up throughout.

My last question is: Would it not be good policy for a first-class popular medical school to limit the number of pupils which it will accept to its capacity to give them proper instruction in laboratory work, in practical anatomy, and in clinical medicine and surgery? Of course, each faculty is prepared to assert that its own school now does this, and will disapprove of fixing any limit to the number of its pupils; nevertheless, it appears to me, as an outsider, that there are at least two or three medical schools in this country which would act wisely if they would fix a limit to the number of students which they would receive either in the first or in the third year, or in both, and enforce this limit by competitive examination or by higher fees, or by both. It would bring the best men to them, and would enable them to do thoroughly good work.

A LAND WITHOUT A MICROBE. — The Spitzbergen group of islands, in the Arctic region, is said to be the most sterile place on the earth. Analysis of the air, water and soil of Spitzbergen shows an extraordinary poverty of these regions in bacteria. While the air of the streets of Paris contains on an average 51,000 bacteria, that of the Arctic Sea contains only three per cubic metre. The water of Spitzbergen not only is devoid of any pathogenic micro-organisms whatever, but is also entirely free from all kinds of bacilli.

CRYSTALLINE DEPOSITS IN THE URINE: THEIR CAUSATION AND RELATION TO RENAL DISEASES.¹

BY EDWARD M. GREENE, A.M., M.D.

THE object of this paper is to consider the conditions under which crystalline deposits are formed within the urinary tract, the injurious effects of these crystals on the kidneys, and the treatment. We will limit our inquiry to uric acid and calcic oxalate, which are by far the most frequent and important of the inorganic crystalline substances found in the urine.

Uric Acid. — This is present in normal urine and has also been found in the blood as well as in the liver and spleen, and, to a less extent, in the brain, pancreas and muscles. The amount excreted daily depends greatly upon the diet, varying from half a gramme on a vegetable diet to as high as even two grammes on an animal diet. It occurs only in traces in the urine of herbivora, and may be absent in that of carnivora. On the other hand, in the urine of birds and reptiles it is the chief nitrogenous ingredient. In various diseases the quantity in the urine is increased, and, at times, as in gout, uric acid accumulates in the blood and is deposited in the tissues. It is generally conceded that uric acid is formed in the tissues, and merely excreted by the kidneys. Experimental evidence points to the liver as the place of formation of uric acid, and it is probably formed by the synthesis of ammonia and lactic acid. Ebstein, however, thinks it is chiefly produced in the muscles and bone marrow.

Uric acid may be described as a less oxidized product of proteid metabolism than urea; but there is no evidence to show that the former is a necessary antecedent of the latter. On the contrary, all the facts known go to show that uric acid is produced by a somewhat different process of metabolism from that which results in urea formation. As pointed out by Foster, "We have no evidence to prove that the cause of this divergence lies in an insufficient supply of oxygen to the organism at large. On the contrary, uric acid occurs in the rapidly breathing birds, as well as in the more torpid reptiles." "Urea is the form adapted to a fluid, and uric acid to a more solid excrement."

Uric acid is extremely insoluble in water, one part of uric acid requiring about 15,000 parts of cold water and 18,000 parts of boiling water. It is insoluble in all dilute acids. It dissolves freely in weak solutions of the carbonates of lithia, potash and soda and in common phosphates of soda. The amount of uric acid capable of being held in solution in the blood depends on the degree of its alkalinity.

Calcic Oxalate. — Although widely distributed throughout the vegetable kingdom, oxalic acid occurs only in very slight amount in the animal organism, and then always in combination with calcium. Calcic oxalate is insoluble in water, ammonia and acetic acid. It is readily dissolved by mineral acids, and to a less extent by solutions of sodic phosphate or urate; chloride of sodium, sulphate of sodium, chloride of potassium, and even urea, aid in its solution, though in slight degree. It occurs in urine both in solution and in the form of octahedral crystals and dumb-bells. Neubauer has frequently found tolerable amounts of calcic oxalate in solution in the urine when no trace of

¹ Read before the Boston Society for Medical Observation, March 5, 1894.

It was discovered in the sediment; but he has also frequently tested normal urine for calcic oxalate with a negative result, so that it is doubtful whether this substance is to be reckoned among the normal or abnormal constituents of human urine.

The calcic oxalate found in urine is derived from two sources: (1) Articles of diet and drugs; (2) As a secondary product of the decomposition of animal, mineral, or vegetable substances.

The first class is composed principally of sorrel, rhubarb, tomatoes, oxalic acid when used medicinally, gentian, saponaria, etc.

The second source is illustrated by the formation of oxalic acid from the oxidation of uric acid, kreatin, leucin, etc., and from the imperfect oxidation of sugar, starch and salts of the vegetable acids, whereby these, instead of being wholly transformed into carbonates, become in part oxalates which contain less oxygen. It is, moreover, probable that oxalates may be formed from carbonates and bi-carbonates when a part of their oxygen is removed from them by a process of reduction. These facts in a measure explain why oxalic acid may be found in the human system under favorable circumstances; thus after taking carbonated drinks, as champagne and seltzer water, in disturbances of respiration where the supply of oxygen is diminished, and after eating sugar in excessive amount, although the special conditions under which this formation takes place are still undiscovered. [Neubauer.]

Oxalic acid, though insoluble in water, is kept in solution in the blood and enabled to pass through the walls of the blood-vessels in the kidney, and thus appear in the urine, through the solvent action of sodium phosphate, and, to a less degree, by that of chloride and sulphate of sodium and even of urea.

It is thus seen that uric acid and calcic oxalate result from defective processes of metabolism, and affect the kidney only by throwing upon it the labor of their excretion and by the formation of crystalline precipitates in the renal tubules and pelvis of the kidney.

It is extremely important to determine the conditions under which these substances crystallize in the urine, and to study the effect of their prolonged action on the kidneys. For this purpose I have tabulated the records of 600 analyses of urine made by me during several years past, in all of which careful microscopical examinations of the sediment were made. No hospital or dispensary examinations are included, as these were not all made with equal thoroughness. In many of these cases the urine was normal, although there usually were symptoms which suggested the advisability of an examination. In very few cases included in these records were there more than one or two specimens from the same patient.

Of the total number of 600 examinations

A crystalline sediment was present	180 times or 30 %
Uric-acid crystals were found	102 " 17
Calcic-oxalate crystals were found	108 " 18
Both calcic-oxalate and uric-acid crystals were found	30 " 5

In all the cases containing these crystalline sediments the reaction was acid in every case and usually strongly so.

Of 72 times in which uric acid alone was found,

Crystals were present in large amount	30 times
Albumen was present	45 "
Casts were present	36 "
Blood was present	20 "
Sugar was present	6 "

Of 78 times in which calcic oxalate alone was found,

Crystals were present in large amount	53 times
Albumen was present	44 "
Casts were present	38 "
Blood was present	16 "
Sugar was present	0 "

Of the 80 cases in which both calcic oxalate and uric acid were present,

Albumen was found	18 times
Casts were found	15 "
Blood was found	8 "

The specific gravity of 30 specimens containing much uric acid was

Below 1,015 in	6 cases
From 1,015 to 1,019 in	5 "
From 1,020 to 1,024 in	5 "
From 1,025 to 1,029 in	12 "
Above 1,030 in	2 "

Or, in other words, it was below 1,020 in 11 cases, and at or above 1,020 in 19 cases.

Of 53 cases in which calcic oxalate was present in large amounts the specific gravity was

Below 1,020 in	6 cases
From 1,020 to 1,025 in	19 "
Above 1,025 in	28 "

To summarize, then, a crystalline deposit was found in nearly one third of all the examinations which were made. Calcic oxalate and uric acid were found with very nearly equal frequency, each being present in about 18 per cent. of the examinations, although large amounts of calcic oxalate were twice as frequent as large amounts of uric acid.

Albumen was present in nearly two-thirds of all the cases containing a crystalline deposit, and was equally frequent with both kinds of crystals. In a little more than half the cases it was present only as a very slight trace; and in the others it very seldom exceeded one-eighth per cent.

The nitric-acid test, and boiling with a drop or two of acetic acid, were the only tests used for albumen; and the latter proved the more delicate. By a "very slight trace" is meant the smallest amount of albumen which caused very slight but distinct cloudiness when boiled.

Casts, usually of the hyaline or finely granular variety, were present in 89 of the 105 cases in which albumen was found, and were also present in four cases in which no albumen was detected. Usually the number of casts is small and they are associated with mucoid threads.

Blood was found in more than a fourth of the cases of uric acid, and in about a fifth of the cases of calcic oxalate. In only four cases was it present in sufficient amount to be suspected by its appearance to the naked eye. In all other cases a few or a moderate number of blood globules were found by the microscope alone.

Sugar was present in one-twelfth of the uric-acid cases, but was never found with calcic oxalate.

Acidity was almost always marked with uric acid, but less so with calcic oxalate.

Specific gravity was above 1,020 in two-thirds of the uric-acid cases, and in nearly nine-tenths of the calcic-oxalate cases.

The diagnosis of chronic parenchymatous or interstitial nephritis could not be made in more than 18 of the 105 cases in which albumen and crystals were present.

We may then fairly infer that the remaining 87 cases illustrate the considerable amount of irritation of

the kidneys produced by urine containing crystalline deposits.

In the entire number of 600 examinations, albumen was found 340 times from all causes.

Comparing this number with that of the cases of albuminuria due to crystalline irritation (87), we find that the latter cause accounted for nearly one-fourth of all the cases of albuminuria.

It is well known that both uric acid and calcic oxalate may be precipitated from the urine after it has been voided. All acid urines invariably deposit uric acid sooner or later. In perfect health the acid held in solution, by its combination with alkaline bases, does not deposit its uric acid, even after it has been voided, unless it stands for a considerable time. The precipitation of uric acid is caused by the acid fermentation of the urine, during which the extractive coloring-matter is decomposed with the formation of free lactic and acetic acids. Uric acid thus precipitated twelve to twenty hours after emission has no pathological significance. The crystals which separate in this manner are usually larger than those which are found in the urinary tract, and many of them will be found adhering to fibres of cotton or other foreign substances. The bulk of the uric-acid crystals is also found on the top of the natural sediment or adherent to the sides of the vessel. Crystals of calcic oxalate also may form slowly in the urine after it has been voided owing to the chemical decomposition of the acid sodium phosphate, which is the principal substance holding the calcic oxalate in solution. Such crystals are generally larger than those which are formed within the body. Indeed, the latter are often so minute that they appear hardly larger than bright points even under a powerful microscope. In case of doubt the presence of a slight trace of albumen, and especially of blood globules, would point to the formation of these crystals in the kidney or bladder.

The amount of crystalline uric-acid sediment cannot be taken as an index of the actual amount of uric acid excreted. On the contrary, Roberts frequently found that those days on which a spontaneous deposit occurred, showed less uric acid than those days on which no uric acid was spontaneously deposited. The amount of uric acid actually excreted presents considerable variations in the same individual from day to day.

The quantitative estimation of uric acid is a difficult matter and is of slight importance as uric acid in solution is comparatively harmless. Though urea may be decomposed into uric acid, both by artificial means in the laboratory and within the human body, exact observations have failed to show that there is any inverse correspondence between the excretion of the two substances; usually urea and uric acid increase and decrease together.

The conditions of the urine which cause precipitates of uric acid are stated by Roberts to be as follows: (1) high acidity, (2) poverty in mineral salts, (3) low pigmentation, (4) high percentage of uric acid.

The degree of acidity is probably the most important element.

Clinically the excretion of uric acid is markedly increased in the febrile state, in certain diseases of the liver, in tuberculosis, rickets, scurvy, leukæmia, and after an attack of gout. It is diminished during the paroxysm of gout. I have found a very large amount of uric-acid crystals in the urine of a rather delicate boy, six years old, whose father and grandfather both

had chronic, gouty joint-inflammations. Such a case illustrates the importance of hereditary influences. In the production of uric acid, especially, habits of luxurious eating and drinking combined with deficient muscular exercise are important factors.

Von Jaksch found uric acid present in the blood in all those disease processes in which oxidation was disturbed, either directly, as in affections of the lungs, such as pneumonia, or indirectly, as in anæmia, in which the oxygen-carriers are deficient.

In view of these practical observations, as to the relation of oxygen to uric-acid production, the theoretical inferences drawn by Foster (quoted above) from the formation of uric acid in birds are found not to apply to man. According to Haig, the amount in the blood rises and falls with the degree of alkalinity, as uric acid is soluble in alkalies, and all circumstances which increase the alkalinity are associated with an increase in the amount of uric acid in the circulation.

The conditions favoring calcic-oxalate formation seem to be somewhat different from those concerned in uric-acid formation. In the latter, we are more likely to find that the system is overloaded with nitrogenous material the oxidation of which is hindered by a deficient supply of oxygen. In other words, the organs concerned in the process of assimilation and oxidation are overcome by the excessive work imposed upon them. The formation of calcic oxalate depends rather upon a disturbance of function in these organs, so that we find that oxaluria is associated with dyspeptic and neurasthenic conditions in which the vital processes are at a low ebb. This opinion is somewhat strengthened by the result of examinations which I made of urine of fifty different patients, taken at random, at the McLean Asylum. Crystalline deposits were found in 28 cases—nearly one-half of the patients examined. Calcic oxalate was almost twice as frequent as uric acid. Albumen was found with the crystals 13 times; blood was found with the crystals 11 times; casts were found with the crystals 12 times. The specific gravity was over 1,020 in 16 of the 28 cases; and it was over 1,025 in 13, reaching 1,033, 1,040, 1,040 and 1,041 in 4 cases, without the presence of sugar.

Comparing these results with those previously given, we see that a crystalline deposit, especially of calcic oxalate, is much more common in the insane than in other patients. The latter generally took very little exercise, ate as little as possible, and often suffered with melancholia or nervous prostration—in short, were in a poor physical and mental condition.

The question then arises whether "lithuria," and "oxaluria" are themselves diseases, as some hold, or only symptoms of many diseased conditions. Many writers have described an "oxalic-acid diathesis" which is accompanied by all the symptoms met with in dyspepsia, hypochondriasis and neurasthenia, and corresponds with the condition attributed by some to spermatorrhæa. But all of these symptoms may be present without oxalate of lime; and, on the other hand, a large amount of oxalate of lime may be found apart from any of the above-mentioned symptoms.

We are forced to conclude, therefore, that the term "oxaluria" must be restricted to the narrow definition of the occurrence of a deposit of calcic oxalate in the urine. "Lithuria," likewise, simply implies a deposit of urates or uric acid. In this narrow sense the symptoms produced by deposits of uric acid or of calcic

alate are simply those of varying degrees of irritation of the kidneys and urinary tract.

A distinction should be made between slight, occasional deposits and large quantities occurring persistently. Almost every one has probably had at some time or another a few crystals in the urine, and these without particular significance. But where there frequently a considerable deposit an abnormal state must be recognized, and one which calls for treatment. The most obvious danger is the liability to the formation of calculus.

More insidious and harmful is the condition of long-continued hyperæmia of the kidney, due to irritation, which may end in chronic interstitial nephritis, the so-called "gouty kidney." In his description of the contracted kidney, Strümpell says: "In the pelvis of the kidney, which is often somewhat dilated, there are frequently a number of uric-acid concretions. Striated uric-acid infarctions in the pyramids are a very characteristic mark of the gouty, contracted kidney." He also says that "experience teaches us that there are three chemical substances which may favor the development of contracted kidney: alcohol, lead and uric acid. Chronic alcoholism is often to be regarded as the most probable cause of renal contraction, especially in people who have 'lived well' otherwise, and have become corpulent."

This latter condition is what we have just shown to be the most important factor in uric-acid formation, and it is not impossible that alcohol produces its harmful effect on the kidney partly through its influence in favoring the production of uric acid. Chronic lead-poisoning and gout, Strümpell also says, "often lead to the development of contracted kidney, in which we probably have to do with the noxious action of an abnormal amount of uric acid on the renal parenchyma." "Intense worry and strain of business" are causes assigned by Osler and others. These conditions also we have shown to be productive of calcic oxalate and uric acid by disordering the digestive and metabolic processes generally.

Professors Da Costa and Edward S. Wood, in recent papers, speak of the frequency with which albuminuria is produced by renal irritation caused by urine which is concentrated and contains uric acid or calcic oxalate. It is to this cause also, in many cases, that Professor Wood attributes the so-called albuminuria of adolescence.

The occurrence of albumen in these cases is often intermittent, and I have found that it is much more likely to be present in the early morning urine, as this is more likely to become concentrated and to contain crystals, owing to the necessary abstinence from food and drink during the sleeping hours.

In organic nephritis, on the other hand, albumen is much more abundant after the ingestion of food, the damaged condition of the renal capillaries allowing the albumen thus supplied to go directly into the urine.

This point is illustrated by the case of a young man who came to my office one morning last April to be examined for life-insurance.

He was twenty-three years of age, a clerk in a business office, well developed and apparently in very good health. He said he felt perfectly well in every way, and there was no prejudicial family history. On examining the urine, I was surprised to find one-tenth per cent. of albumen. The urine was highly-colored, specific gravity of 1,022, acid, without sugar, and con-

tained a considerable sediment. The latter, on settling, showed under the microscope much calcic oxalate, a little mucus and a few hyaline casts. A few days later he came in in the afternoon and brought a specimen of urine passed before breakfast, which proved, on analysis, to be the same in every respect as the above, except that there was not quite so much albumen and very little calcic oxalate. The specimen passed in my office the same afternoon was of normal color, specific gravity 1,020. No albumen, sediment slight, and found to contain nothing abnormal.

On June 22d, after he had been taking water and diuretics, a morning specimen showed a specific gravity of 1,010, no albumen, and a slight sediment which contained nothing abnormal. After this he neglected treatment, and I did not see him again until October 14th. On that day the early morning urine was high-colored, specific gravity 1,022, albumen one-tenth per cent., sediment slight, but contained a little calcic oxalate, a little mucus and a few hyaline casts. The afternoon specimen of the same day had a specific gravity of 1,012, contained no albumen, and I was unable to find either calcic oxalate or casts in the urine. He informed me that a few days previously he had been accepted for life insurance by another company, although he had informed them that he had been rejected by me in April for albuminuria. The medical examiner had had him call at his office several days in succession, and had found no albumen. On inquiry, I found that his calls had always been in the afternoon, and he was required, as is customary, to pass his water in the presence of the examiner, who became satisfied that the urine was normal. It would seem advisable in such cases with a high specific gravity for the medical examiner to contrive to secure a reliable specimen of early morning urine. I have seen the patient several times since, and usually find albumen and calcic oxalate in the morning urine. The only cause for this condition that I could discover was a habit of drinking very little water, and a disinclination to take any more exercise than he was obliged to take in walking to and from the office.

(To be continued.)

CASES OF ACUTE PNEUMONIA IN CHILDREN.

BY F. GORDON MORRILL, M.D.

THE tables given in this paper include a great majority of the cases of pneumonia which have been treated in the wards of the Children's Hospital, the exceptions being a few of which the records are not sufficiently complete to be useful.

The period of life (second to twelfth years inclusive) during which children are eligible for admission to the hospital must be borne in mind, as it undoubtedly influences the views which experience in this particular institution might lead one to adopt.

By "frank" pneumonia is meant a form of the disease which has been easily diagnosed from the far more serious broncho-pneumonia, and which (so far as our experience at the Boston Children's Hospital is concerned) differs from it as radically as any two acute diseases affecting the same organs can differ in their history, course and prognosis.

The term "frank" instead of "croupous" or "fibrinous" pneumonia, is employed in order to avoid the confusion which has arisen since the comparatively

recent discovery of the fact that there may be considerable quantities of fibrin in cases which are clinically, and (as recently proved) in their bacteriological pathology, broncho-pneumonia. The statement made that both forms and all grades of the disease may coexist in children is not warranted by our present knowledge, and has proved a most unwelcome addition to already existing perplexities.

That a frank pneumonia may terminate by prolonged lysis, that a bronchitis often accompanies it, or that a broncho-pneumonia may involve the whole (?) or nearly the whole of an entire lobe, are facts which when properly weighed do not invalidate the statement in the preceding paragraph.

Cases of prolonged absorption of the products of a frank pneumonia are by no means rare in adult life, and the same thing is occasionally observed during childhood. Cold is assuredly a factor in the causation of frank pneumonia; and a bronchitis giving rise to râles in any or all portions of the lungs may be naturally expected in 15 to 20 per cent of all cases. When a large portion of lung is involved by a broncho-pneumonia the history and predominant symptoms of the case have usually been such as to enable the attending physician to form an early and correct diagnosis.

The very small number of autopsies which have been obtained does not warrant the expression of an opinion concerning the post-mortem appearances of either form of the disease.

Clinically, the children who have been treated in this hospital, have taken their pneumonias almost "straight."

SUMMARY.

Mortality about $1\frac{1}{2}$ per cent. in 72 cases, of which 44 were boys, and 28 were girls.

Average age a little over five years.

Months when admitted: January, 4; February, 6; March, 6; April, 9; May, 7; June, 9; July, 2; August, 4; September, 5; October, 7; November, 3; December, 10. Spring and winter, 42 cases; summer and autumn, 30.

Highest temperature in any case while under observation 106.5° F. Lowest maximum temperature in any case while under observation 101° F. Highest average maximum temperature in 68 cases 104.2° F.

Terminating by crisis (the temperature dropping to normal or below within twenty-four hours) 34. Terminating in "short lysis" (temperature dropping to normal or below in more than twenty-four and less than forty-eight hours) 19. By prolonged lysis 12.

The average critical day in 54 cases was the eighth. In 31 of the cases terminating by crisis it was between the seventh and eighth. The lower lobes have been more frequently involved than any other portions of the lungs. In three cases the location of the disease was central — by which is meant that no signs of solidification could be detected, but the symptoms were sufficiently well marked to make it morally certain that the disease was frank pneumonia. Such cases as terminated in prolonged lysis, showed the physical signs of very slow absorption of inflammatory products with little or no redux crepitation. Pleuritic effusions in connection with frank pneumonia have been rare, and as a rule of small extent. But one case of empyema has been observed.

The disease certainly appears to be very benign so

far as concerns the cases here reported, and the treatment has been quite simple: milk diet; brandy, when indicated; digitalis or strophanthus in cases of irregular or very weak pulse; and occasionally phenacetin, in instances when a high temperature has not been well borne. Pretty free stimulation (two or three ounces of brandy per diem) has been used when a sudden fall of temperature was followed by signs of collapse. No cough mixtures of an expectorant character have been employed; but occasionally an opiate has been given to check troublesome night-cough.

The expectoration of rusty sputa has been exceedingly rare, and the main points upon which the differential diagnosis has been made are: sudden onset of the attack (history of cough accompanied by high fever, nausea, convulsions or delirium, and abdominal pain), the quiet type of the dyspnoea and detection of solidification giving rise to coarse (as a rule) crepitant râles, bronchial respiration and exaggerated vocal resonance.

The average age of the children admitted for frank pneumonia, five years ten months, as compared with the age of those entering with broncho-pneumonia (a little over three years) would seem to show pretty conclusively that in New England the latter disease is most prevalent among children who are of an age to easily shed and rapidly proliferate the epithelium of their mucous membranes.

The following table includes the cases of broncho-pneumonia which have been treated in the wards with the exception of five cases, in which the records are very incomplete. The total number of cases (33) when compared with the number of frank pneumonias (72) goes to prove which is the most common type of the disease between the second and twelfth years.

This hospital is a poor field for the observation of broncho pneumonia, which is essentially a disease of very young children and infants, and is apt to break out in epidemic form in institutions where large numbers of them are congregated. This epidemic type is infectious, and is characterized by its sudden onset. It is this form of the disease (particularly in cases where a large extent of lung is involved) which has given rise to conflicting views of both clinicians and pathologists. The children treated in this institution are of an age which usually exempts from this fatal form of broncho-pneumonia, and the non-admission of measles affords further protection. Many of the cases reported here might be more properly called chronic broncho-pneumonia, or phthisis following closely after the acute form of the disease. Cases in which an acute broncho-pneumonia is merely the death mask of a miliary tuberculosis are usually of an explosive type, and prove rapidly fatal. So far as I am aware, we have had but one example of this form of the disease in the hospital, and the diagnosis in this case was made at the autopsy.

A brief summary of the table shows that 14 of the cases were girls and 19 boys: and the average duration of illness from its commencement (as nearly as could be ascertained) in 29 cases has been between 10 and 12 weeks. There are so many types of the disease, varying from that which suddenly overwhelms a child (as in the epidemic and very infectious kind, such as occurs among children who are crowded together) to the long sickness which eventually kills by subacute or perhaps fibroid phthisis, that I think it quite impossible to fix any definite average of duration of cases which custom has sanctioned our calling

recent discovery of the fact that there may be considerable quantities of pyogenic organisms in the blood and (as recently proved) broncho-pneumonia in both forms and all children is not without exception and has proved an existing perplexity.

That a frank prolonged lysis, that is, that a broncho-pneumonia or nearly the whole when properly treated, is a precedent in the preceding.

Cases of prolonged frank pneumonia, and the same thing in childhood. Cold of frank pneumonia is rare in any or all usually expected. When a large portion of pneumonia the history of the case have usually tended physician.

"broncho-pneumonia." A very acute attack may prove to be merely the wind-up of a miliary tuberculosis; it may kill in a very few days without the aid of tubercle, or the child may recover quite speedily. On the other hand, a similar attack may be followed by a slow form of pulmonary phthisis; and the period of death, or possibly recovery, is quite indefinite. A mortality of 45 per cent. as in the cases here given, is perhaps what might be naturally looked for in the type of the disease which they represent.

I have been unable to discover in the records any case of so-called "capillary bronchitis," for the reason that when children have presented the symptoms usually attributed to this disease (as they have in one or two instances) they have been treated for, and recovered or died of, *broncho-pneumonia*.

Medical Progress.

REPORT ON THERAPEUTICS.

BY FRANCIS H. WILLIAMS, M.D.

THE UNTOWARD EFFECTS OF ANTIPIRYN, ACETANILIDE AND PHENACETIN.

DR. D. R. PATTERSON¹ states that circulars were sent out to the South Wales Branch of the British Medical Association asking for information as to the alleged ill effects following the administration of antipyrin, acetanilide and phenacetin, the nature and comparative frequency of their occurrence, and their relative importance. Twenty-five replies were received; and these were from men engaged in active practice, in some instances both hospital and private, and residing in different parts of the district. The writer also discussed the subject with many of the members who sent in reports, and thus learned their views at greater length than could be expressed in a circular reply.

Antipyrin. — It is as an analgesic that this drug is prescribed so largely by practitioners, and all are agreed that it is an invaluable remedy. Large doses depress the nervous system. Of the twenty-five reports, seventeen note positive results, varying from an unpleasant diaphoresis to severe collapse. Most of them may be referred to the action on the nervous system, producing exhaustion and collapse following the fall of temperature; and there may be disturbance of the circulation for the same reason or secondarily from the effect on the blood-corpuscles and the production of methæmoglobinæmia. Other symptoms, such as affections of the skin and pronounced psychical disturbance, are more rare. Depression with collapse has usually been noticed after doses given with a view to reduce fever. Thus, a dose of twenty grains was followed in a male adult in a short time by great collapse and fall of temperature, requiring hypodermic injections of ether and digitalis to tide the patient over the difficulty. The writer cites another case in which ten grains given to a lady convalescent from influenza led to extreme depression and collapse; the patient became deeply cyanosed, unconscious and pulseless, and required free stimulation before she was considered out of danger twelve hours later. A small proportion of results such

as these have been observed in children, where regulation of the dose is not so exactly carried out, although the amount borne by a child is often relatively much larger.

Several of the reports call attention to the frequency of depression in pneumonia, and express the opinion that the use of the drug should be very guarded in that disease, one member holding that it is positively harmful even in small amounts. Falk, in his *résumé* of the ill effects of recently introduced antipyretics, mentioned a case of pneumonia where death occurred one hour after the administration of antipyrin, which was regarded as the cause of the fatal result. The stage of collapse is not infrequently ushered in by a feeling of anxiety and great prostration, and the symptoms are sometimes relieved by vomiting. The intensity of depression that may follow even a moderate quantity of antipyrin is illustrated by a case, recorded by the late Paul Guttman, which was sent into the hospital as one of cholera. The patient, a well-developed man, had the symptoms and appearance of the asphyxial stage of cholera-morbus, except that the bowels were confined. On the chest and abdomen was a dull-red miliary rash. Five days previous to his admission, he had taken for headache a fifteen-grain powder of antipyrin twice a day, in all 150 grains, when he fell into this condition. Under stimulating treatment he recovered rapidly. Minor degrees of depression are represented by unpleasant diaphoresis, which may be so profuse as to prostrate the patient temporarily. Continued use of even small doses leads not infrequently to a condition in which the patient complains of loss of energy, is disinclined to exert himself and becomes depressed mentally, in short, there is established an antipyrin habit. Falk mentions headache, giddiness and other nervous symptoms as occasionally brought on by antipyrin.

One of the members report blurring of the vision along with blueness of the lips and finger-nails. Blueness of the lips and face is one of the commonest untoward effects, and was noticed in various degrees, from that which is just perceptible, to a deep cyanosis associated with profound collapse. It is to be explained by the action on the nervous system, and especially the blood by which methæmoglobinæmia is produced. In extreme doses the red cells are destroyed. The circulation of the altered blood through the medullary centres is responsible for many of the symptoms observed.

Several of the reports note cardiac depression. Cardiac failure in cases of pneumonia was frequent even with doses of ten grains. None of the members have apparently had any experience of the occurrence of hæmorrhages reported by Continental writers. Such an occurrence points to the necessity of great caution in the administration of antipyrin in phthisis and typhoid fever. In the former, the rather profuse perspiration produced by the drug is a serious drawback. Two of the reports mention the appearance of a rash after the use of antipyrin. The writers of these reports did not observe various symptoms observed by others, such as convulsions, rise of temperature instead of the anticipated fall, etc.

As to the frequency with which the ill effects are met, all the members agreed that they were very rare. Shortly after the introduction of the drug they were not uncommon, on account, no doubt, of the larger doses then in use. The reports of those who have not

¹ The Practitioner, 1893.

observed any unpleasant after-effects or signs of intoxication show that the doses they were in the habit of giving were, on the whole, smaller. A single dose of ten grains or five grains every three hours is the usual practice of three out of eight who report negative results; others give two ten-grain doses, with an interval of two or three hours between. Two members state that when giving antipyrin as an antipyretic, they always combine it with a stimulant, such as sal volatile, brandy, or tincture of digitalis. In this way large doses, even to the extent of twenty grains every four hours, until 120 grains had been reached, were administered without depression being felt.

Acetanilide (antifebrin).—Its action in lowering temperature is striking, but the disadvantages attending it have seriously limited its administration. The frequent occurrence of symptoms of intoxication, and the alarming appearance they sometimes assume, led many practitioners to abandon its use very early. Eight members report results after a considerable use of the drug; and among them a few speak of its great value when used with due care. The dose generally given varies between five and ten grains, but some give as low as three grains to an adult. The general experience seems to be that the larger doses are soon followed by symptoms of intoxication. Some practitioners combine the drug with a stimulant—brandy, or digitalis, or caffeine—with excellent results. The consensus of opinion gathered from the reports coincides with that generally expressed, that symptoms of depression and collapse are more readily produced and more marked than with antipyrin; and this may be explained by the fall of temperature being greater and more rapid. One observer, whose extensive use of acetanilide makes his opinion very valuable, states that there is less collapse in children than with antipyrin. In pneumonia, the depressant action on the heart renders it very unsafe. Most of the reports mention cyanosis, and to a greater degree than after antipyrin. Anæmia may be induced by the continued use of the drug, and become a grave condition. The anæmia is due to the action of acetanilide on the red blood-cells; minor forms of it are noticed after a few doses.

Phenacetin.—This drug is more free from ill effects than either of the other two drugs. It is generally given in doses varying from five to ten grains, and it is very useful in neuralgia of the fifth nerve, sick-headache, etc. Its depressant action on the nervous system and heart is manifest only when very large doses are given, small amounts taken frequently being borne without ill effects. It is not, however, absolutely free from unpleasant consequences, as is illustrated by a case of Eisenhart. An adult male was given for pain in connection with a carious tooth three powders, each containing fifteen grains of phenacetin, within three and a half hours; half an hour after the last powder palpitation and oppression of breathing came on; later, the palpitation and oppression increased, dulness of hearing came on, and then nausea and vomiting. With the onset of sickness, all traces of intoxication vanished, and the patient felt well. Skin eruptions, chiefly urticarious, are said to follow the use of phenacetin.

[It is not alone the immediate depression which may follow one or two doses of these drugs against which we should guard, but rather the more insidious depression which may follow their continued use in a long illness like typhoid fever but which may not be-

come apparent until the later stages of the disease. It is a good rule to avoid these drugs in serious illnesses where we need to husband the patient's strength. Acetanilide (antifebrin) is the most likely of the three to have an untoward action. — F. H. W.]

STRONG HYDROGEN PEROXIDE ACID SOLUTIONS LOCALLY IN DIPHTHERIA.

Dr. Francis H. Williams,² in an article on diphtheria, outlines in a few words the general treatment of this disease, speaking of the need of special attention to the food of the patient and of the service of alcohol in some cases, and adds that the cases of Behring treated with the blood-serum of immune animals, encourage us to hope that a feasible internal remedy may yet be found. He then goes on to say that at present local remedies are our best means for the treatment of diphtheria, and obviously they are best adapted to those cases that are seen early, before much of the poison has been absorbed, and in which the membrane is accessible. He then briefly touches upon various of the local remedies that have been used, but does not recommend any of them, citing three cases, the diagnosis of which was based on cultures, to show how the membrane may persist under the use of corrosive sublimate. Two of these cases entered the hospital on the third day of the disease and were treated with corrosive sublimate (1 to 10,000) in the one case, and with corrosive sublimate aided by the ordinary solution (7.5 volumes) of hydrogen peroxide in the other. In the first case, the patient was finally discharged on the one-hundredth day of the disease. The corrosive sublimate seemed to have inhibited the growth of the bacilli so that for a time none appeared in the cultures and treatment was therefore stopped; they were, however, apparent later. In the second case, the patient was discharged on the forty-first day of the disease. Both of these patients had weak hearts, and the latter had paralysis. The writer then discusses more in detail the special local treatment which he has found to be most efficient, namely, strong hydrogen peroxide acid solutions, by which he means strength of 25 to 50 volumes (old style 50 to 100); 7.5 volume solutions are weak germicides. He first proved, by experiments made in the laboratory, that the strong acid solutions were efficient germicides against the Klebs-Löffler bacillus; he lays stress upon the important part played by the acid contained in them, and shows that the hydrogen peroxide has the special quality of breaking up and disintegrating certain portions of the diphtheritic membrane without injury to the healthy tissue, thus rendering the bacilli more accessible. In stating his clinical experience, he describes two cases of diphtheria, the diagnosis of which was based on cultures where, although only partial use of the strong hydrogen peroxide solutions was made, good results followed. These two patients entered the hospital on the second day of the disease; in the first case, a final application of the peroxide was made on the fifth day after entrance and the patient left the contagious ward six days later. In the second case, a final application of the peroxide was made on the third day after entrance, on the fourth the throat was clear, and the patient was discharged after being kept under observation ten days longer. In neither case was there cardiac weakness, depression or paralysis.

The writer states that he has found nothing that

² American Journal of Medical Sciences, November, 1893.

will remove the membrane due to the diphtheria bacilli so well as the strong solutions of hydrogen peroxide, gives a general rule for using them, describes the instruments with which they should be applied, and then says that any local treatment must be frequently applied to be efficient, as the bacilli reproduce themselves in a very short period. The use of the strong hydrogen peroxide acid solutions reduces the number of applications to a minimum, as the more thoroughly the membrane is disintegrated and removed the less frequent is the necessity for treatment, and the shorter its duration. The usefulness of good local treatment is in direct ratio to the stage of the disease, the accessibility of the membrane, the age and strength of the patient, and the ability of the practitioner to apply it with the least tax on the patient's strength combined with the greatest destruction of the bacilli. The writer emphasizes the importance of early treatment, and says that the strong hydrogen peroxide acid solutions are the most efficient local treatment of which he knows.

[Further use of these solutions in cases of diphtheria, the diagnosis of which was based on cultures, shows good results, especially in those cases treated early. Over 90 per cent. of those which were treated within the first three days recovered.]

THE OBTAINING AND THE USE OF SERUM FOR THE CURE OF DIPHTHERIA.

Ehrlich, Kassell and Wassermann² in a very interesting paper state that the animals principally used to furnish serum in their experiments were goats, which they found especially adapted to the purpose. The manner of rendering them immune is alluded to and the method of testing the power of the antidote described. By an agreement with Behring the best of the serum made by them was used in several hospitals and the whole number of cases treated was 220, all of which were children. The cases were not selected. These injections of serum confirmed earlier observations in proving them to be perfectly harmless. At first, one injection only was used, but experience gained in the treatment of severe cases induced them later to use repeated injections in certain hospitals. Of the 220 cases treated, 168 recovered and 52 died; 67 of the 220 cases had tracheotomy performed; of these 37 recovered. A table given shows that the success of the treatment by serum depends essentially upon how early in the disease treatment is begun.

The writers noticed that the temperature and pulse were influenced only by the stronger injections. An immediate fall in temperature does not customarily follow the injections of serum, and this may be due to the fact that the pure Klebs-Löffler bacillus was only found in the very early stages of the disease in these cases, and even then it was proportionately rare. In the later days of the disease other bacteria were associated with the diphtheria bacilli, and the antidote for the poison of this bacillus does not counteract that of the other organisms. In some cases where the treatment was begun very early, the writers noticed an almost critical lowering of the temperature and of the very high pulse. They close by saying that the fate of the child is decided in the first three days of the disease and therefore the serum should be injected as early as possible; that according to their experience the initial dose in serious cases and in all cases of tracheotomy should be double that of the light cases;

that the treatment with serum should be continued according to the course of the fever, to the pulse, and to the local appearances; that the total amount injected should be according to the severity of the case.

THE TREATMENT OF ITCHING.

Dr. Edward Bennet Bronson,⁴ describes at some length the means that may be employed to remove this distressing affection, and groups them as follows:

Measures to Remove Local Excitants.—These will include, first of all, such as directly tend to prevent scratching. Irritating contacts of all sorts should be most scrupulously avoided. Attention should be given to the underclothing. Woollen is almost never tolerated. The clothing next the skin should be of the softest material—cotton, linen, or possibly silk. Of further importance is the avoidance of immoderate temperatures, whether of heat or cold, and especially of sudden changes, which are peculiarly apt to excite itching. The local excitants may not only be extracutaneous, but also intra-cutaneous. Often they are incidental to the trophic changes of one of the so-called pruriginous diseases, in which case the treatment of the pruritus is included in that of the disease of which the itching is a symptom. When they arise from the toxic materials conveyed to the skin by the blood, the endeavor is to eliminate these materials by depurative remedies, more especially diaphoretics and diuretics. These measures failing or proving insufficient to secure the desired rest, it becomes necessary to have recourse to certain sedatives.

Sedatives.—Used internally, these are apt to be disappointing. The degree of general sedation that is required to affect the nerves of the skin, in so intense a disturbance as pruritus often is, affords a sufficient reason why this method of treatment is usually objectionable. Further than this, the depressing and atonic after-effect on the nervous system tends to exaggerate the general hyperæsthesia, which is already essentially an atonic condition, and thereby increases the tendency to itching. Especially objectionable on this score are most of the narcotic sedatives. The bromides, on the other hand, are often indispensable, and may be required in liberal doses. To avoid the enervating effects of loss of sleep, sulphonal or some other hypnotic is occasionally needed. In connection with this class, two internal remedies, namely, cannabis indica and gelsemium, are worthy of mention. The latter has proved of benefit in some cases, more especially according to the writer's experience in protracted cases of urticaria, but the doses required are so large as to forbid their long continuance. Finally, the antipyretics, phenacetin and antipyrin, have some effect upon pruritus, though less than upon the sensation of pain. The local sedatives used in this disease are generally far more satisfactory in their effects than the remedies just considered, especially where the disease is limited in extent. They are for the most part agents that tend to retard vital action. The fact that many of them are antiseptics probably implies something more than mere accidental coincidence. Typical among the remedies of this class is the group which includes carbolic acid, salicylic acid, salol and thymol, all antiseptics, and all having undoubted virtues as antipruritics. Carbolic acid is, perhaps, all considered, the most reliable and most generally useful antipruritic. It is preferably employed in oils or oint-

² Deutsche Medicinische Wochenschrift, April, 1894.

⁴ Medical Record, 1892.

ment. The following has been largely employed by the writer:

R. Acid. carbolic	31-ij
Liq. potass.	3i
Ol. lini.	3j M.
Sig. Shake before using.		

Salicylic acid and salol, though less energetic in their effects, act similarly to carbolic acid. They may be used in combination with other drugs, or by themselves in oils or ointments, or sometimes alcohol, and also in superfatted soaps. Thymol is also useful in certain cases, but, on account of its irritating effect, cannot be used when the skin is very sensitive. Corrosive chloride of mercury also has a reputation as an antipruritic. Cocaine has proved disappointing for two reasons: first, because of the difficulty of making its action felt through the intact epidermis; and, second, for the reason that any tissue, when long or frequently subjected to its action, suffered a certain atony and enervation that seems to render it more predisposed after than before to the irritation or irritability the drug was intended to alleviate. These objections by no means preclude its use entirely. It is often resorted to with most satisfactory results in localized forms about the mucous orifices, upon raw or abraded surfaces, and sometimes with appreciable effect even where the epidermis is apparently intact. Hot water, to be effective, should be over 100° F., and the applications should be prolonged for several minutes.

Sensory Stimulants. — Electricity, whether in the form of galvanism or faradism, has sometimes proved of decided benefit. Strychnia, in those cases of pruritus which may be called atonic, is a remedy of value.

Substitutive Irritants. — One of the best palliatives of itching is menthol, together with the peppermint preparations generally. Menthol relieves itching as it relieves pain, not by direct inhibitory action on the molecular movements of the sensory nerves, but chiefly, if not solely, as the writer believes, by substituting an exaggerated temperature sense for the perturbed sense of contact, or for the sensation of pain. It is usually employed in alcoholic solutions (grs. v – x to ʒi), and may be used in ointment. It is also with advantage combined with salol or thymol.

Alteratives of Cutaneous Nutrition. — They include not only absorbent and anti-catarrhal remedies to remove the products and curtail the processes of incidental inflammations which may act as contributory causes of the itching, but such agents as tend to control blood-supply and overcome hyperæmia. In this way act diaphoretics, and possibly diuretics, as well as by their substitutive and eliminative or depurative action. Thus it is probable that jaborandi, which is recommended by so many writers, acts in all three ways. This drug is especially useful when the skin is hot and dry, and where it has become the depot of noxious materials deposited from the blood, as, for example, in the itching of icterus. The local remedies belonging to this class include certain resinous or tarry substances. Such are ichthyol (five to ten per cent.), occasionally tar, resorcin (three per cent.), and benzoic acid or benzoin. Hydrogen peroxide has also proved beneficial.

Motor Depressants. — Among the internal remedies already mentioned, gelsemium and jaborandi belong to this class. Another remedy, more especially recommended in urticaria, is atropia. The good effect of

this drug in urticaria, when used in full doses, such as are always required to produce this effect (from one-hundred-and-fiftieth of a grain upward) is probably due to its secondary action; in this action the muscles relax and the vessels are dilated. Hot-water applications take the first place in local remedies belonging to this class. Here, also, may perhaps be included such local sedatives as hydro-cyanic acid, cyanide of potassium, corrium juice, tincture of arnica and chloroform.

Dr. Bronson closes the article by illustrating the therapeutic principles laid down by means of special forms of the affection.

Recent Literature.

Anæsthetics and their Administration. A Manual for Medical and Dental Practitioners and Students. By FREDERICK W. HEWITT, A.M., M.D. (Cantab.). With illustrations. London: Charles Griffin & Co. 1893.

We have before alluded to the many advantages of the system of regularly appointed anæsthetists which prevails in English hospitals. This work of Mr. Hewitt is a proof of those advantages. He has put the careful experience of many years into a book which will stand easily at the head of all works on the therapeutic administration of anæsthetics. The data are well arranged under four parts: Preliminary Considerations; The Administration of the Selected Anæsthetic; The Management and Treatment of the Difficulties, Accidents and Dangers of General Anæsthesia; The Condition of the Patient after Administration.

Mr. Hewitt has given the question of "Chloroform or Ether?" careful consideration, and makes no hesitancy in advocating ether as the surest, safest and best anæsthetic for general use. The whole book is worthy of study by all who have to do with anæsthetics, either as surgical instructors, pupils or general practitioners.

The Johns Hopkins Hospital Reports. Report in Gynecology, II. Baltimore. 1894.

This volume of more than 400 pages is very interesting, not only as giving an idea of the amount of work done in this department in Johns Hopkins Hospital, but also as illustrating its thoroughness and its value from an educational standpoint. The material at hand has been so carefully worked over and utilized that it is full of suggestions for the practitioner. The result is a series of monographs, nineteen in all, most of them by Dr. Kelly, which are of varying importance and interest, but all of them well worth study. They are fully illustrated with figures and plates, which add much to their value.

Of especial interest may be mentioned the articles on operations for the suspension of the retroflexed uterus, urinalysis in gynecology, the importance of employing anæsthesia in the diagnosis of intra-pelvic gynecological conditions, and one hundred cases of ovariectomy performed on women over seventy years of age.

This series of reports would be a valuable addition to any gynecologist's library.

ARTERIO-SCLEROSIS AND ARTERITIS: MODERN VIEWS AS TO ETIOLOGY.

THE conception of arterio-sclerosis as a general disease of the arteries finding expression in interstitial inflammations of various viscera, originated with Lancereaux in 1871, and, independently, a year later with Gull and Sutton. The latter designated the condition as an "arterio-capillary fibrosis," and they supposed the capillary net-work to be invaded by a "hyaline degeneration"; while Lancereaux more correctly defined the disease as a generalized endarteritis, followed by renal, cardiac, or other endarterites, and subsequent interstitial inflammation.

This notion of a general idiopathic arterial disease with visceral manifestations has since been established as an irrefragable medical doctrine, has been fruitful in practical applications, and it has been shown that there is perhaps no more common disease of the age in which we live than arterio-sclerosis. "Longevity," says Osler (in quoting from a much older authority), "is a vascular question, for a man is only as old as his arteries. To a majority of men death comes primarily or secondarily through this portal."

Arterio-sclerosis and atheroma designate two distinct localizations of a slow morbid process, atheroma being applied to the inflammatory or degenerative changes as met with in the larger vessels. Arterio-sclerosis, according to Gull and Sutton, Mahomed, Huchard, and others, is the parent of atheroma and of all the fatty, fibroid and calcareous changes in both large and small vessels. The primary morbid process is an obliterating endarteriolitis of the vasa-vasorum or nutrient vessels of the artery; dystrophy, local infiltration and degeneration in the media and adventitia follow. "These lesions lead to a weakening of the wall in the affected area, at which spot the proliferative changes commence in the intima, particularly in the subendothelial structures, with gradual thickening and the formation of an atheromatous button or patch. A similar process goes on in the smaller vessels, and it can be seen on section that each patch of endarteritis corre-

sponds to a defect in the media, and often to changes in the adventitia."

According to this view, in this as in other dystrophic diseases where the nobler elements perish from lack of their nutritive supply, the connective-tissue elements proliferate and form an overgrowth which by its presence obstructs function and damages or destroys the surrounding structures; or, if fragile and of low vitality the new growth becomes necrosed and fatty, and may eventually be removed or undergo the calcareous transformation.

The question whether the visceral scleroses (being connective-tissue inflammations) are always primarily diseases of the arterial system, is answered differently. Mahomed, with Gull and Sutton, taught that the nephritis is but a manifestation of a diathesis or poison which affects synchronously the cardio-vascular system. In all cases, "the blood-poison, of whatever nature it may be, produces certain changes in the cardio-vascular system, at first functional and afterwards organic by inducing high arterial tension and subsequently hypertrophy of the heart and thickening of the vessels; and at the same time it affects not only the kidneys but also the other excretory organs which all alike become congested in their efforts to excrete the poison; hence in these organs certain changes occur — interstitial, if the disease be chronic, epithelial, if acute."¹

There is no doubt that this is a part of the truth, but it is not all the truth, and pathologists have recognized the fact that there is an interstitial nephritis that is primary, and may, at least in its early stages, be independent of general arterial disease — this is the case with the senile kidney and saturnine nephritis, according to Charcot. Certain chronic fibroid pneumonias, according to the same authority, may always remain local; so also a variety of syphilitic hepatic sclerosis, hypertrophic cirrhosis, and (according to Lancereaux) common alcoholic cirrhosis.

As to the nature of the poison, there is not entire agreement among pathologists respecting a disease which, according to Mahomed's estimate, affects to a greater or less extent seventy-five per cent of all persons who pass the age of sixty. Lancereaux, who has written much on arterio-sclerosis, is sure of but one causal agent, which he calls *herpetism*, which he regards as a "vaso-trophic neurosis, always manifesting itself by multiple affections of divers parts and systems such as hæmorrhoids, varices, dry and gouty and rheumatic arthritides, migraines, eczematous diseases, etc." As for alcohol, he denies its causal influence, except so far as it favors development of the peculiar diathesis; that the abuse of this poison causes local fatty lesions of the heart and arteries he as positively affirms.

Gueneau de Mussy also insists on the influence of herpetism in the production of atheroma, and includes gout and rheumatism as being the diathetic maladies *par excellence*. He prefers the term *arthritism*² to her-

¹ Lectures in Lancet, 1879.

² De l'Atherome Arteriel: Leçons de Clinique Médicale, t. 1.

petism. This author, whose contribution to the subject of atheroma will always possess great scientific value, concludes from twenty-five carefully tabulated clinical observations in which the autopsy was conducted with great care, that "the lesions produced in the arteries by alcoholic excesses, are earlier, deeper, more rapid and more pronounced than those produced under the influence of all other causes."²

It has been disputed whether syphilis is ever a cause of generalized arteritis; certainly the arterial lesions which it produces, in the tertiary stage, are frequently limited to arteries with prominent lymphatic sheaths as those of the cerebrum. The same may be said of malarial endarteritis, which always affects the large vessels, especially the aorta, taking the form of gelatinous or indurated patches (Lancereaux).

Over-eating, overwork of the muscles (by increasing the peripheral resistance and raising the blood pressure), and renal disease (by increasing the toxic quality of the blood and thus poisoning the vessels) have been reckoned as causes: and Huchard assigns a considerable rôle to mental emotion (worry and anxiety), which, he thinks, acts by producing spasm of the arterioles and vascular hypertension.

In senile arterio-sclerosis, complex causal factors exist which may be principally classed under the heads of dystrophic and toxic. This is really a diffuse arterio-sclerosis with extreme degeneration of the arterial coats, with nodular, beady indurations in the smaller and calcareous patches in the larger arteries. It is astonishing with what apparent good health many old persons will live, and to an advanced age, who have long had calcareous arteries and granular kidneys.

There is a close relationship between *plethora* and arterio-sclerosis, as Germain Sée has pointed out.⁴ Two causes, he says, favors its development: (1) physical causes, namely, intra-vascular obstacles which increase vascular pressure and owe their origin to disregard of hygienic laws, excesses or sedentary life; (2) chemical, autoxic and infectious agents; alcohol, gout, diabetes, syphilis. There are two classes of persons who early develop increased vascular tension: (a) those that take much food and little exercise and develop adipose tissue; (b) then, sometimes, anæmic individuals who are obliged to lead a sedentary life. Every copious repast determines a certain temporary plethora. If more food is ingested before the previous plethora has been disposed of, there gradually is established a permanent vascular repletion.

After showing how increased adiposity obstructs the abdominal circulation and raises the pressure in the aorta, he points out the fact that a considerable venous distention is also produced, showing itself in superficial varices, hæmorrhoids, predisposition to pulmonary catarrh. The development of sclerosis is always preceded by this stage of increased vascular tension. This abnormal pressure is the principal cause of the general endarteritis.

ANNUAL REPORT OF THE MASSACHUSETTS GENERAL HOSPITAL.

THE eightieth annual report of the Massachusetts General Hospital and McLean Asylum for the year 1893, while not showing any marked changes in this over recent years, describes enlargements and improvements already begun, which will increase the usefulness of the two institutions in the near future. The report opens with a clear and concise summary by a Committee of the Trustees, of the principal items of interest.

The year shows a deficit of over \$29,000, the largest in the history of the hospital, a great part of which, however, is owing to necessary repairs and alterations connected with the buildings. There was a falling off in the receipts in the second six months of \$6,741, while the increase in disbursements was \$8,470. This falling off is mainly due to the temporary closing of Ward B, also to the fact that the year has been one of great and exceptional financial depression.

On December 1st, the new office of examining physician to out-patients was made, the previous arrangements for examination and registration not having proved wholly satisfactory. The usefulness of this office in preventing the mingling of cases of contagious diseases with the out-patients in the waiting-rooms has already been proved.

In the hospital building some considerable and important changes have been made. The old Treadwell Library-room has been adapted to give a much needed addition to the work-room of the enlarged staff of house-officers, while the Treadwell Library itself has been transferred to a new room in the second story. Additional house-officers' rooms, with suitable bath-rooms, have been provided. Changes and additions to the amphitheatre building include an addition of one story, containing a new sterilizing-room for the preparation of surgical instruments and dressings. A new dressing-room for the surgeons has also been provided. A gift of \$50,000 has made it possible to erect a new isolated ward for contagious diseases; such a ward has been needed since the foundation of the hospital. A card catalogue of all the cases at the hospital from 1871 has been started. An appeal is made for a well-equipped laboratory; and for funds for the general expenses both of the hospital and of the asylum. The percentage of free patients at the hospital is enormous, while the subscriptions for free beds have diminished.

The buildings of the new McLean Asylum at Waverley have progressed steadily during the year. The description of four of them, not included in last year's report, appears in this one. Two interesting reports are printed; one upon the occupation of patients at the asylum, by the Superintendent; the second by a special committee on the case of W. H. King, a patient in the asylum, whose retention has been the source of much litigation.

In the hospital the total number of patients admitted was 3,524, an increase of 200 over the previous year. The number of out-patients was 26,527, with a total

² De l'Atherome Arteriel: Leçons de Clinique Médicale, t. i., p. 304.

⁴ Arterial Disease; Sajou's Annual, 1890; Medical Bulletin, March 17, 1894.

attendance of 86,579, about the same number as in 1892.

In the asylum, although the average number of patients, 177, was larger than in previous years, the number of admissions and discharges was less. The coming removal of the asylum from Somerville to Waverley will be an important epoch in its history; the buildings, roads, and other works at Waverley are now so far advanced that they may easily be finished before September 29, 1895, when the estate at Somerville is to be vacated.

MEDICAL NOTES.

THE NUMBER OF PATIENTS AT KING'S COLLEGE HOSPITAL.—During the year just closed there were 2,372 patients admitted to King's College Hospital, London, and 24,000 out-patients treated.

MR. GLADSTONE OPERATED UPON FOR CATARACT.—Mr. Gladstone was successfully operated upon for cataract by Mr. Nettlehip last week, and has been making an excellent recovery.

THE MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA. At the annual meeting held May 21st, Dr. John B. Roberts, of Philadelphia, was elected president for the ensuing year.

DR. PEPPER'S SUCCESSOR AS PROVOST OF THE UNIVERSITY OF PENNSYLVANIA.—Mr. Charles C. Harrison has been elected Provost of the University of Pennsylvania, to succeed Dr. Pepper. He has accepted provisionally.

SAD DEATH OF A BROOKLYN, N. Y., PHYSICIAN.—Dr. Charles James, of Brooklyn, died on May 22d from an accidental dose of tincture of aconite. He was twenty-seven years old, and a graduate of the Long Island College Hospital Medical School.

A SUCCESSFUL SPLENECTOMY.—Dr. James Murphy, of Sunderland, England, did a splenectomy upon a woman forty-five years old, on April 25th. The operation was undertaken for abscess and hypertrophy. The wound healed promptly, and at last reports the patient was making a satisfactory progress.

A LEPER HOSPITAL FOR LOUISIANA.—At the request of the Senators and Representatives from Louisiana, the Secretary of War has given New Orleans and the State of Louisiana the right to use the Government military reservation, at Fort Pike, for a hospital for lepers and patients with contagious diseases.

THE THIRTEENTH INTERNATIONAL MEDICAL CONGRESS.—Dr. Baccelli has written to Señor San Martín, the delegate of the Spanish Government to the International Medical Congress at Rome, that there is a generally expressed desire that the Thirteenth Congress, the one following that in Russia, should be held in Madrid.

CONGRESS OF THE FRENCH SURGICAL SOCIETY.—The French Surgical Society will hold its annual meeting this year at Lyons, probably in the early part of October. This is the first time the meeting will have

been held outside of Paris. The matter was decided by a *plébiscite*, and the result is regarded as a victory for the advocates of decentralization.

PLAGUE AT HONG KONG.—A serious epidemic of disease is reported from Hong Kong. Since the middle of April over a thousand deaths have occurred. The disease is said to be similar to the plague which decimated the population of Hochow ten years ago; but as the cholera is at present reported to be general in Canton, the disease at Hong Kong is not unlikely to be of the same character.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—During the week ending at noon, May 30, 1894, there were reported to the Board of Health of Boston the following numbers of cases of acute infectious disease: diphtheria 37, scarlet fever 65, measles 24, typhoid fever 12. There were no cases nor deaths from small-pox during the week. There are no patients at the Canterbury Street Hospital. The last case of small-pox was discharged from Gallop's Island this morning.

THE MASSACHUSETTS MEDICAL REGISTRATION BILL.—The Medical Registration Bill was passed by the House on Monday May 21st, and now awaits the Governor's signature before becoming a law.

COLLEGE OF PHARMACY COMMENCEMENT.—The twenty-sixth annual commencement exercises of the Massachusetts College of Pharmacy was held in Association Hall, Boston, May 23d. Seventeen men received degrees.

THE SOMERVILLE, MASS., HOSPITAL.—The annual report of the Somerville Hospital shows that 325 patients were cared for during the past year, the average number being 14. The total running expenses were \$9,482.08, the average cost of each patient being \$12.72 per week.

PHYSICAL TRAINING AT WELLESLEY COLLEGE.—The Committee on Health and Physical Training of Wellesley College calls attention to the urgent necessity of improved facilities for both in-door and out-door exercise, and systematic hygiene and physical training for the young women of the college such as are abundantly provided for colleges for young men.

THE CONNECTICUT SCHOOL VACCINATION LAW CONSTITUTIONAL.—The Superior Court, at Hartford, Conn., has decided, in a suit brought against the New Britain School Board to compel them to admit unvaccinated children to the public schools, that the law giving the school board authority to order all school children vaccinated, and to exclude those not vaccinated from the schools, is constitutional.

THE NEW CATALOGUE OF THE MASSACHUSETTS MEDICAL SOCIETY.—A new and attractive Catalogue of the Officers, Fellows and Licentiates of the Massachusetts Medical Society from 1781 to the close of 1893 has just been prepared by the Treasurer, Dr. E. J. Forster, and issued by the Society. A special effort was made to give full names and to eliminate all

initials; and this has been done in nearly every instance, there being but thirty-five Fellows whose full name is not known. The total number of Fellows since the foundation of the Society has been 4,905, of whom 1,927 are living. In addition to these there were 178 Licentiates who never became Fellows of the Society. There have been 145 Honorary Members, of whom 7 are now living. In addition to the statistical tables and lists there is an interesting chapter of historical memoranda.

NEW YORK.

NEW YORK COUNTY MEDICAL ASSOCIATION AND THE CODE. — At a meeting of the New York County Medical Association held May 21st, a resolution was unanimously adopted to the effect that the Association re-affirms its adherence to the code of ethics of the American Medical Association, and instructs its delegates to the approaching meeting of the latter in San Francisco to unite with other delegates from the State of New York in maintaining the code as it now stands.

THE MEDICAL DEPARTMENT OF THE NATIONAL GUARD OF NEW YORK. — At this meeting Dr. Joseph D. Bryant, who has been Surgeon-General of the State for the last ten years, read a valuable paper on "The Medical Department of the National Guard: Its Status in Two Decades." In it he spoke of the general inefficiency of this department of the militia up to 1884 and of the radical reforms that have taken place since that date. It is only due to Dr. Bryant, as was clearly brought out in the discussion on his paper by regimental surgeons, that these reforms have been instituted and carried out by the Surgeon-General himself, who has devoted much time and attention to the matter.

PUBLIC HEALTH. — The reports of the Bureau of Vital Statistics still continue to show an excellent state of the public health. In the week ending May 26th there were reported 721 deaths, which represents an annual death-rate of but 19.28 per thousand of the estimated population. The mortality from pneumonia has diminished to a considerable extent, but is still larger than that from consumption. During the week the deaths from the former numbered 89 and from the latter, 82. Diphtheria continues by far the most fatal of the zymotic diseases, and caused 56 deaths. The deaths from scarlet fever were 16, from measles, 8, and from cerebro-spinal meningitis, 5. A considerable number of cases of small-pox are still reported every week, and there were four deaths from it during the week named. There is but little typhoid fever in the city, and only three deaths were caused by it.

THE TENTH ANNUAL MEETING OF THE FIFTH DISTRICT BRANCH. — The tenth annual meeting of the Fifth District Branch of the New York State Medical Association was held in Brooklyn on May 22d. The address of the President, Dr. J. D. Rushmore, of Brooklyn, was on "The Prevention of the Disagreeable and Dangerous Symptoms produced by Ether as a General Anæsthetic." A number of eulogistic addresses were made on the late Dr. Alfred L. Carroll, and bio-

graphical sketches were read of other members deceased during the past year. Among the papers read were the following: "The Dietetic Treatment of Consumption," by Dr. T. J. McGillicuddy; "Report of a Case of Chronic Peritonitis with Intestinal Fistula — Celiotomy, Enterorrhaphy, Recovery," by Dr. F. H. Wiggin; "The Treatment of Chronic Oöphoritis by Electricity," by Dr. Edward Sanders. The meeting was closed by a discussion on "Vaccination," which was opened by Drs. F. A. Jewett, S. E. Jelliffe and H. H. Morton, of Brooklyn.

PHILADELPHIA.

RESIGNATION OF DR. EDWARDS. — Dr. Jos. F. Edwards has resigned from the State Board of Health.

THE HOUSE-TO-HOUSE VISITATION, which accomplished so much good last summer in improving public health, has again been ordered by the city authorities on general sanitary grounds.

THE ESTABLISHMENT OF SECTIONS IN THE COLLEGE OF PHYSICIANS. — The establishment of Sections in the College of Physicians has proved very profitable, the meetings being well attended and the discussions valuable. A plan is under consideration whereby the papers and discussions shall appear in their proper position as contributions to the annual volume of Transactions of the College.

NON-VACCINATED CHILDREN MAY ATTEND THE PUBLIC SCHOOLS. — Owing to a conflict of authority between the City Board of Health and the Board of Education, the latter has withdrawn its prohibition recently issued, against non-vaccinated children attending public schools. In view of the fact that no epidemic is threatened at present, they were not willing to resort to extreme measures.

JEFFERSON MEDICAL COLLEGE APPOINTMENTS. — The Trustees of the Jefferson Medical College discussed the proposed plan of re-organization which included the establishment of the office of Provost, and concluded to postpone further consideration of the subject until next fall. Dr. S. MacCuen Smith was elected Clinical Professor of Otolaryngology, and Dr. W. Joseph Hearn, Clinical Professor of Surgery, and Dr. E. P. Davis, Clinical Professor of Obstetrics.

THE AMERICAN MEDICO-PSYCHOLOGICAL ASSOCIATION. — This Association held its semi-centennial meeting in Philadelphia at the Continental Hotel May 15th to 19th. Dr. John Curwen of the Pennsylvania State Hospital for the Insane at Warren, presided and delivered a very valuable address. Governor Pattison delivered an Address of Welcome in which he reviewed the progress of the treatment of the insane in this State since 1844. An address, by invitation, was delivered by Dr. Weir Mitchell, who pointed out many flaws in prevalent methods of treating the insane and described an ideal hospital. At the closing session the society elected Dr. Mitchell to honorary membership. Dr. Edward Cowles, of Somerville, Mass., was elected President and Denver selected as the next place of meeting.

Miscellany.

A CLASSIFICATION FOR INFECTIOUS DISEASES.

At a recent meeting of the New York Academy of Medicine, Dr. W. H. Thomson read a paper on the need of a more accurate nomenclature for infectious and contagious diseases, and offered the following classification:

(1) Infectious diseases are due to the presence of their respective living micro-organisms in the body.

(2) Infectious diseases are divisible into three classes: *a*, communicable, *b*, non-communicable, *c*, septic.

(3) The communicable diseases are those whose origin is from an animal body, examples of which are small-pox, Asiatic cholera and tuberculosis.

(4) The non-communicable infectious diseases are those whose origin is not from an animal body, but from a place or thing, examples of which are ague, yellow fever and miasmatic diseases in general.

(5) The communicable diseases are divisible into two classes, according to the ordinary modes of their communication: *a*, into the contagious, *b*, into the non-contagious communicable diseases. The contagious communicable diseases are those in which simple proximity to the sick is sufficient to communicate the infection; examples of which are scarlet fever, measles, small-pox, diphtheria, mumps, etc. Isolation of the sick in these cases is, therefore, needful to prevent infection. The non-contagious communicable diseases are those in which the communication is not by simple proximity to the sick, but through intermediate means of communication. Isolation of the sick with them, therefore, is neither needful nor effective in comparison with measures directed against intermediate means of infection; examples are typhoid fever, Asiatic cholera and tuberculosis.

(6) The septic infectious diseases are those in which infection is introduced through a wound or abrasion; examples are erysipelas, hydrophobia, tetanus, etc.

THE SYMPTOMATIC TREATMENT OF DISEASE.

In a recent address before the Harveian Society, Dr. Samuel West said:

"The treatment of symptoms is often spoken of with some contempt—not, I think, by clinical physicians, who are not prepared to discard remedies because they cannot explain their action. It is sufficient for them that experience proves the value of the drugs they use. It is true that we have so far no remedies which will kill disease germs in the body, and therefore directly cure any germ disease; but the germs produce poisons, and these by their action on the body, in all probability cause the symptoms of the disease. These poisons we may be able to neutralize or destroy, if we cannot kill the germ. What the poisonous substances produced are we do not know, and for antidotes to them we are, and have long been, groping in great darkness, it is true; yet I think it is not unlikely, when these poisons are isolated and investigated outside the body, that among the old and once-trusted remedies, which empiricism has discovered and fashion discarded, will be found some of the true antidotes we want, and thus the symptomatic treatment of disease, now regarded as so unscientific and irrational, be discovered to rest upon a truly scientific foundation."

Correspondence.

THE MEDICAL REGISTRATION BILL.

Boston, May 28, 1894.

MR. EDITOR:—Is the health of the people of this Commonwealth as safe in the hands of ignorant "practisers" of medicine as it is in the care of educated physicians? If so, then our calling is the only profession or vocation of which such a statement can truthfully be made.

Granted, that the more knowledge the doctor has, the better care he will be able to give the sick and wounded, is it desirable and possible to raise the standard of medical education? How shall this be done? The various medical schools, as a rule, are doing what they can in this direction.

Can anything be done to protect the innocent and ignorant sick and wounded from these pretenders, who have never studied in any school, or anywhere else, and who are destitute, not only of knowledge and experience, but of character and good repute? Is it desirable, that any aid or protection should be extended to the unfortunate victims of disease, when seeking for help in their distress, or shall they be left to the tender mercies of the medical bunco-steerers of the community?

It is assumed by the writer, that there are not a few sensible people in this State, who think and feel strongly, that some light, as to the qualification of doctors, should be given the people through legislation. This is the object of the medical bill. It is designed to benefit the people and not the doctors. The educated physicians of Massachusetts ask for no protection and no legislation for themselves, or for their business against quackery. They are abundantly able to take care of themselves. But as no class in the community sees the evil results, the needless suffering, both mental and physical, and great waste of money, arising from the unlimited license of quackery, as do the physicians, upon them falls the duty of calling attention to the matter.

The medical bill undertakes in no way to say who shall practise medicine, or what "school" or "system" any one shall practise, or what sort of a physician or doctor or "healer" any one may or may not employ. It simply says, that every one in this State, who puts the title of "Doctor" to his name in public, shall be possessed of a reasonable amount of knowledge of his business. That is all. It is not a great step in the right direction, but it is something.

It is here authoritatively stated that, "the medical member of the senate" is the author of the bill, and that, of all men, he is the one most responsible for its origin, and present status. His great regret is, that it could not have been made more complete.

Very truly yours,

GEORGE W. GAY, M.D.

METEOROLOGICAL RECORD.

For the week ending May 19th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Deaths reported 2,254: under five years of age 849; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fever) 348, acute lung diseases 327, consumption 241, diphtheria and croup 152, diarrhoeal diseases 63, scarlet fever 35, whooping-cough 25, measles 23, typhoid fever 17, cerebro-spinal meningitis 13, small-pox 7, erysipelas 6.

From whooping-cough Brooklyn 7, New York and Pittsburg 4 each, Philadelphia and Cambridge 3 each, Cincinnati 2, Cleveland and Nashville 1 each. From measles New York 7, Brooklyn and Cleveland 6 each, Philadelphia 4. From typhoid fever Philadelphia 6, New York 3, Brooklyn 2, Washington, Cincinnati, Pittsburg, Lowell, New Bedford and Holyoke 1 each. From cerebro-spinal meningitis New York 6, Cleveland 4, Holyoke, Taunton and Fitchburg 1 each. From small-pox New York 5, Brooklyn 2. From malarial fever New York 6, Brooklyn 1. From erysipelas New York and Brooklyn 3 each.

In the thirty-three greater towns of England and Wales with an estimated population of 10,458,442, for the week ending May 12th, the death-rate was 18.2. Deaths reported 3,649: acute diseases of the respiratory organs (London) 272, measles 232, whooping-cough 139, diphtheria 74, scarlet fever 56, diarrhoea 40, fever 31, small-pox (Birmingham 6, London 4, Bradford 2, Manchester and Oldham 1 each) 14.

The death-rates ranged from 9.5 in Derby to 25.2 in Birmingham; Blackburn 17.0, Bradford 15.4, Cardiff 16.1, Halifax 14.6, Leeds 16.5, Leicester 14.6, Liverpool 23.8, London 18.4, Manchester 20.6, Newcastle-on-Tyne 17.3, Norwich 16.3, Nottingham 19.4, Portsmouth 12.6, Sheffield 17.9.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 19, 1894, TO MAY 26, 1894.

Leave of absence for four months, is granted MAJOR PETER J. A. CLEARY, surgeon.

CAPTAIN WILLIAM G. SPENCER, assistant surgeon, having been found by an Army retiring board, incapacitated for active service, will proceed to his home.

CAPTAIN ALONZO R. CHAPIN, assistant surgeon, is relieved from duty at Fort Hancock, Texas, and ordered to new Fort Bliss, Texas, for duty.

FIRST-LIEUT. FRANCIS A. WINTER, assistant surgeon, is re-

lieved from duty at new Fort Bliss and from temporary duty at old Fort Bliss, Texas, and ordered to Fort Hancock, Texas, for duty at that post.

CAPTAIN GEORGE MCCREERY, assistant surgeon, will, upon the abandonment of Fort Sidney, Nebraska, report in person to the commanding officer, Fort D. A. Russell, Wyoming, for duty at that post.

CAPTAIN ROBERT B. BALL, assistant surgeon, is relieved from temporary duty at Fort Monroe, Virginia, and ordered to Fort Adams, Rhode Island, for duty, relieving CAPTAIN WILLIAM C. BORDEN, assistant surgeon.

CAPTAIN BORDEN, on being thus relieved, is ordered to Fort Snelling, Minnesota, for duty at that post, relieving CAPTAIN CHARLES F. MASON, assistant surgeon.

CAPTAIN MASON, on being thus relieved, will report in person to the Superintendent of the U. S. Military Academy, West Point, N. Y., for duty at that post.

LIEUT.-COL. FRANCIS L. TOWN, deputy surgeon-general, is relieved from temporary duty in the office of the medical director, Department of the Missouri, and will report in person to the commanding general, Department of Texas, for duty as medical director of that Department.

CASUALTY.

COLONEL JOSEPH C. BAILY, assistant surgeon-general, died May 16, 1894, while en route from El Paso to San Antonio, Texas, in the line of duty.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING MAY 26, 1894.

B. R. WARD, assistant surgeon, detached from Bureau of Medicine and Surgery and to the "Vermont."

C. A. SIEGFRIED, surgeon, ordered to the U. S. S. "Cincinnati."

MAINE MEDICAL ASSOCIATION.

The forty-second annual meeting will be held in Common Council Chamber, City Building, Portland, Me., Wednesday, Thursday and Friday, June 13, 14 and 15, 1894.

WEDNESDAY, JUNE 13TH.

"Typhoid Fever, with Some New Notions Regarding its Treatment." By E. M. Fuller, M.D., Bath. Discussion by A. K. F. Meserve, M.D., Portland; S. J. Bassford, M.D., Biddeford. "An Interesting Obstetrical Case." By Geo. Goodwin, M.D., Millbridge. President's Address. "Treatment of Hemorrhoids by Clamp and Cautey." By B. B. Foster, M.D., Portland. Discussion by S. H. Weeks, M.D., Portland. "Puerperal Eclampsia." By H. B. Palmer, M.D., Phillips. Discussion by Alfred Mitchell, M.D., Brunswick. "The Artificial Feeding of Infants." By W. B. Small, M.D., Lewiston. Discussion by B. F. Bradbury, M.D., Norway; Geo. H. Brickett, M.D., Augusta. "The Principles of Antiseptic Surgery." By W. L. Dana, M.D., Portland. "Surgery of the Ovary." By A. Palmer Dudley, M.D., New York. Discussion by Alfred King, M.D., Portland. "A Unique Case of Urinary Calculi." By S. H. Weeks, M.D., Portland. "The Code Question from the Standpoint of a General Practitioner." By D. A. Robinson, M.D., Bangor.

THURSDAY, JUNE 14TH.

"The Surgical Demands of a Country Practice." By W. P. Giddings, M.D., Gardiner. Clinic at the Maine General Hospital at 11.30 o'clock, with special reference to the illustration of Surgical Dressings. Election of officers for the ensuing year. "Symphysectomy with Report of Case." By J. B. O'Neill, M.D., Portland. Discussion by Stanley P. Warren, M.D., Portland; F. E. Small, M.D., Portland. "The Chemistry of Decomposition." By Prof. F. C. Robinson, M.D., Brunswick. Report of Cases: "Caesarian Section," "Extra-Uterine Pregnancy." By S. C. Gordon, M.D., Portland. Report of "Cases of Abdominal Section." By Wallace K. Oakes, M.D., Auburn. Business. Annual Oration. By Henry H. Smith, M.D., Machias, at 8 P. M.

FRIDAY, JUNE 15TH.

Reports of delegates to other medical societies. Voluntary papers or reports of cases. Report of the Board of Censors. Unfinished business.

The Business Committee desire that members will come prepared to contribute the results of their experience and observation, by reports of cases, with clinical notes or queries upon diagnosis, treatment, action of remedies, etc.

DR. JOHN A. DONOVAN, President, Lewiston.

DR. CHAS. D. SMITH, Recording Secretary, Portland.

RECENT DEATH.

GEORGE J. ROMANES, Fullerian Professor of Physiology in the Royal Institution of London and Rosebury Lecturer on Natural History in the University of Edinburgh, died in London, May 23d, aged thirty-six years.

Addresses.

SUPRAPUBIC HYSTERECTOMY:

THE ADDRESS OF THE CHAIRMAN OF THE SECTION OF OBSTETRICS AND DISEASES OF WOMEN, OF THE AMERICAN MEDICAL ASSOCIATION, SAN FRANCISCO, JUNE 5, 1894.

BY JOSEPH EASTMAN, M.D., LL.D.,

Formerly Professor of Anatomy and Professor of Gynecology and Abdominal Surgery, Central College of Physicians and Surgeons, Indianapolis, Ind.

MR. CHAIRMAN, LADIES AND GENTLEMEN:—It seems best on this occasion to turn aside from the usual custom of reporting progress in the department of obstetrics and gynecology, a subject which has been so often and ably presented by my predecessors, and call your attention to the present status of suprapubic hysterectomy as viewed from the standpoint of personal observation and clinical research, with the hope that I may contribute in some small measure to the profitable discussion which I am quite sure will follow the reading of the valuable papers on your programme.

It is not my intention to report a series of operations made for the removal of symmetrically formed pear-shaped tumors, with well-defined broad ligaments; with uterine arteries easily accessible and seen pulsating in their anxiety to be ligated; tumor ligaments and arteries dealt with by some definite method; each operation made in exactly so many minutes, and all the patients making uneventful recoveries. The literature of the subject is already cursed with such productions. Therefore I would rather suggest such means and methods as experience has taught me will furnish the best possible results in dealing with tumors by no means symmetrically formed; with broad ligaments displaced and disorganized by nodular masses interfering with the ligation of arteries and the easy formation of pedicles.

Despite the efforts of some to name a distinct method of operating because a flap is made here, or a ligature placed there, the problems of suprapubic hysterectomy are rapidly nearing their solution. Those engaged in the work are divided into two classes: first, those who have been and are yet satisfied with forming a pedicle and fixing the same in the abdominal wound; second, those who were not satisfied that this method was the best that could be devised, and who have been earnestly endeavoring to reach some method which shall disregard morphology of tumor, of broad ligaments and the location of uterine arteries.

On February 3, 1887, knowing full well that abdominal fixation of the pedicle in suprapubic hysterectomy had at that time given the lowest rate of mortality, I decided not to operate in that way, but planned and executed an operation which in every essential feature was an extirpation of almost the entire cervix. A large cautery passed three times down through the cervix in reality destroyed a large portion of what little cervix I had left. A rubber drainage-tube was inserted for vaginal drainage. In a recent discussion in the *New York Journal of Obstetrics and Gynecology*, the operations by Stimson, Krug, Baer and myself are spoken of as if they were all operations of total ablation of the uterus. If these operations are to be considered, then the operation by Stimson in Novem-

ber, 1888, was antedated by my determination to secure something better than the abdominal fixation of the pedicle on February 3, 1887.

It is not my purpose to occupy time in discussing questions of priority in making an operation, although the operation, including the use of my hysterectomy staff, as I demonstrated it at the International Medical Congress in Berlin, has since been made many times by Krobak, of Vienna, and numerous American operators, with great satisfaction.

I concede the fact that where a given fibroid tumor has no nodular masses in the region where we would form a pedicle or imbedded in the broad ligaments, and where the abdomen is not exceedingly fat, the abdominal fixation has given results, in the hands of expert operators, in a very high degree satisfactory. So far as I have been enabled to read the writings of its warmest advocates, none of them have mentioned the very strongest point in its favor; namely, that in this method we have practically one wound; whereas, in the total or partial extirpation method we have two wounds, the one in the abdomen, the other in the pelvis, the latter extending through connective-tissue, rich in lymphatics, down to the vagina—an incubator for many varieties of bacteria which cannot always be sterilized and maintained aseptic during an operation.

I became well convinced a number of years ago that the use of the clamp of Keith or the serre-neud of Kœberle for controlling hæmorrhage from the neck of the uterus was based upon the idea that the spiral or curling branches given off from the uterine arteries really penetrated the tissues of the uterus, including its cervix. Some seven text-books on anatomy which I have examined state that these branches penetrate the uterus. I have a number of times, with fingers on the broad ligaments and their contained vessels, cut directly through, seizing the spurting vessel and securing it later. I have also peeled off the uterine arteries from the sides of the uterus and then cut off the cervix with little or no hæmorrhage.

These studies were for the purpose of reducing the number of ligatures,¹ long or short, to become incapsulated or slough off, through the vagina, and also to economize the time for their thorough application.

Here is a nodular mass fed and nourished by a capsule—a capsule containing the venous and arterial papillaries. It is well known to every gynecic surgeon that these nodules can be peeled out of the capsule without ligating a single artery. What I have stated regarding the nourishment of this nodule by its network of capillaries and not by the penetration of the arteries, for surgical purposes, holds true with reference to a uterus disorganized by a fibroid tumor or tumors no matter how large or how small; not only of the fibroid uterus, but the normal uterus as well; not only of the uterus but its entire cervix down to the external os.

I here present a specimen (see p. 554); and to my mind it marks a new era in the removal of fibroid tumors by hysterectomy, for the reason that the uterine arteries were not ligated at all. I went down between the uterine arteries and the uterus. The uterine arteries were absolutely left within the pelvis of the woman, not a single ligature being used except those

¹ A ligature to secure the uterine arteries will often secure a certain amount of muscular and connective tissue, and is one of the possible sources of infection of the wound; hence the importance of having as few ligatures constricting tissue in this work as possible.

which tied off the ovarian arteries and a small section of the upper portion of the broad ligaments.²

Then in addition to solving the problem as to what to do with the pedicle, by deciding not to have any, we also solve the problem as to what to do with the broad ligaments and especially their contained uterine arteries by simply leaving them in the pelvis of the patient.

In this case I simply controlled the circulation in the ovarian artery by ligating the upper portion of the broad ligaments with a strong ligature, then, cutting the broad ligaments above the ligature, began with this serrated gouge (see cut) to peel down the broad ligaments, keeping the gouge close to the tumor, being especially careful in the interspaces between the nodules not to puncture or tear the uterine artery, or any of its branches. From time to time nicking the edges of the peritoneum with these button-pointed scissors, with the serrated cutting edge, I pushed it forward under the peritoneum anteriorly and posteriorly so as to make anterior and posterior flaps. Then pushing with the serrated gouge, I carefully worked around the tumor until I had reached the uterine cervix, and then proceeded with still greater caution not to cut the cer-

vix nor its capsule, but to push it down, as I now slip my cuff toward my elbow with the fingers of my right hand. The enucleation of the lower portion of the uterus, including its cervix, reminds me of Professor Sayre's admonition when removing the head of the femur for hip-joint disease. He says, "I take this oyster knife and work my way past the trochanters major and minor, then make sure to get beneath the periosteum close to the bone." "Then," he used to say, "d—n the anatomy, stick close to the bone," and proceeded in peeling off the periosteum until he had the entire head of the femur out of the acetabulum.

As I reached this lower part of the cervix, my hysterectomy staff was passed up the vagina. I then removed the entire cervix, cutting a little opening on to the staff, slipping a strip of gauze in the fenestra of the staff. When the staff was withdrawn, this was brought down in the vagina, the upper portion of the gauze being packed into the pocket from which the cervix had been enucleated. The flaps which I had dissected off from the tumor and cervix were brought together by buried suture over the ligatures which had included the ovarian arteries, so that their raw ends also came into the wound. Several rows of buried suture were used, so that all raw edges made by peeling out the cervix were deeply buried so as to prevent leaking into the peritoneal cavity, the gauze being dragged down into the vagina a little each day, facilitating perfect drainage in that direction. This operation is the realization of the ideal. Heretofore, all of us had simply been idealizing the real. In a lecture delivered in July, 1893, I closed with a series of conclusions. From them I quote the third, to wit: "Where the neck of the uterus remains small, abdomen not too fat after the ovaries and tubes have been tied off, the pedicle may be fastened in the lower angle of the wound and give satisfactory results." To this conclusion stated at this time I have this to add: Where such anatomical conditions exist, enucleation of the cervix can be done in less time than the manufacturing of a pedicle, the adjustment of the serro-nend and elastic ligature. Furthermore, abdominal fixation of the pedicle cannot be accomplished, in all cases.

It is to the class of cases where no pedicle can be formed to fix in the abdominal wound that I would invite the best-directed efforts on the part of those who have a heartfelt interest in this class of suffering women.

One's per cent. of recoveries would undoubtedly be much better if, after making a careful examination which discloses a tumor deeply imbedded in the pelvis, we would discourage operative procedure; but in my first 100 hysterectomies I found a number of cases were gangrenous tumors and tumors containing gangrenous nodules, causing slow death in some cases and rapid death in others from septicæmia. Within the last six months I have operated on seven women who had either gangrenous fibroid tumors or fibroid tumors with gangrenous nodules. In five of the cases the nodular masses were deeply imbedded in the pelvis, and two of the cases were operated on within one week. In each case a nodule as large as a coconut was completely imbedded in the broad ligaments, having been developed from low down on the side of the uterus, and in both cases the nodular masses were in an advanced state of gangrene, they having caused temperature ranging from 100° to 103°. In two other cases the subserous tumors had become gangrenous

² Sauter, of Constantine, Germany, three-quarters of a century ago removed the uterus by the vagina without clamp or ligature (See article by Dr. Guido Bell, *Indiana Medical Journal*, February, 1894). Further, the enucleation of the cervix by the vagina was made by Langbeek in 1813, by Recamier in 1829, and by Malgaigne at a later date (See article by Dr. Robert Rayborn).

from small twisted pedicles. In each case rapid and well-pronounced septicæmia threatened the life of the patient. Surely, the technique of suprapubic hysterectomy is not complete until guided by sound surgical principles. We have methods and means for this class of cases. I am pleased with the rapidity with which we can ligate the upper portion of the broad ligaments, cut the same loose from the tumor, peeling the peritoneal covering off from the tissue, leaving a little subserous tissue beneath it, enucleating nodular masses, and directly find ourselves down on the uterine cervix close to the external os, with only an occasional bleeding from some enlarged arterial twig.

The most serious question in my mind in these cases is how to properly drain the cavities from which these nodular masses have been enucleated. In a recent case I packed the cavity in the broad ligament, from which I had enucleated a gangrenous mass as large as a cocoanut, with iodoform gauze, bringing the same out at the side of the pedicle which I had fixed in the abdominal wound. In addition to the gauze, I placed a metallic drainage-tube well down into the pocket. I wished to be absolutely certain that this cavity was thoroughly drained, believing that in other cases where I had trusted to gauze alone for drainage it was not satisfactory. In the first forty-eight hours we pumped out of this drainage-tube fully a pint of black blood, which, coming from the cavity occupied by this gangrenous nodule, gave a considerable odor, notwithstanding the thorough washing of the cavity through the drainage-tube. I believe it would be better in such cases to secure the most thorough vaginal drainage—not only through the opening made by the enucleation of the uterine cervix, the same being packed with gauze surrounding a drainage-tube, but by making a free and direct opening from the bottom of the cavity in the broad ligaments into the vagina. It has been taught that the danger of removing cysts or fibroids from the broad ligaments lies in the disturbance of important plexuses of nerves. My observation leads me to believe that the shock is not materially great in such enucleation, and that the bad results following such operations are due to the use of drainage which does not properly drain. But while I secured the most perfect drainage in the case referred to by bringing the drainage-tube up to the side of the pedicle, I would not advise abdominal fixation of pedicle in cases where nodular masses are enucleated from the broad ligaments and even imbedded in the region of the cervix, where we would form a pedicle, believing that these cases can be treated more successfully by removal of the entire cervix, with free vaginal drainage.

As I suggested at the beginning of the paper, one of the great objections to the total extirpation of the cervix and vaginal drainage is that we make an additional wound and have a possibility of vaginal infection. I concede, further, that it is not always possible to render the vagina surgically aseptic. . . . In a large per cent. of cases, however, a thorough washing of the uterine cavity, packing the same with iodoform gauze and then stitching the external os will prevent any purulent fluid from escaping into the vagina during our handling of the tumor. Then, thoroughly washing and even scrubbing the vagina with a brush and packing the same (including all its cul-de-sacs) with iodoform gauze, will give us a reasonable assurance that this tube has been made aseptic and reduces

the dangers of infecting the peritoneal cavity to the minimum.

In a conversation with Dr. Bantock, of London, I expressed the hope that in the near future we would be able to remove fibroid tumors with the same low rate of mortality which follows our work in removing ovarian cysts. He replied: "This can never be done, for the reason that the anatomical conditions are essentially different." Carefully reflecting over this statement, I have become thoroughly convinced that a more thorough study of the essential anatomical conditions which exist in an abdomen containing an ovarian cyst would enable us to bring the rate of mortality of the two operations to something approximating equality.

I have a number of times left the greater portion of the uterine arteries to remain in the pelvis of the patient; but from the results I had, I was thinking that the possibility of infection through the rich chain of lymphatics at the side of the uterus was greater in such cases than where broad ligaments were thoroughly constricted by ligature all the way down to the opening in the vagina. This led me to prefer cutting around the cervix to enucleating it. But carefully reflecting over the statement of Dr. Bantock that the anatomical conditions were essentially different in fibroid tumors from what they are in ovarian cysts, I have become convinced that we often find fault with the technique which we have used in treating the pedicle when the cause of death ought to be explained in some other way. For example, when the parietes of the abdomen are rendered thin by pressure of an ovarian cyst, the blood-supply is reduced so that all the intra-abdominal viscera are more or less anæmic. This condition is in marked contrast with the hypernutrition often present in and about the pelvis which contains a fibroid tumor. I am quite sure that deaths occur in consequence of our almost losing our heads in the determination to make the pedicle and all pertaining thereunto as perfect as possible, and neglecting perfect approximation of the abdominal incision, always as long as the tumor, including its peritoneum. I have many times cut through two inches of fat to reach a fibroid tumor, and unless such a wound be thoroughly closed by three rows of sutures, the internal one being fine silk with stitches not more than one-fourth of an inch apart, and then making absolute serous approximation, there is danger of infecting the peritoneal cavity by the wound leaking into the abdomen. Too often we take extreme precautions to nicely adjust the outer integument when it would be better, if any leakage from the wound is to occur, that it shall pour outward, and not inward. Again, the more vascular condition of the peritoneal cavity and its contained viscera in cases of fibroid tumors, as compared with ovarian cysts, warn us of the greater intolerance of rough manipulations, making it necessary to protect intestines and viscera as much as possible during operation by hot sterilized towels or sponges, by temporarily bringing the wound together over the intestines with a temporary stitch or vulsellæ, and, above all and over all, by the most thorough irrigation of the peritoneal cavity with water at a temperature of not less than 110°, not only after the work has been completed, but at intervals during the work, so as to undo the harm we do to the vaso-motor nerves distributed to the pelvic and abdominal viscera. Half-a-dozen pitchers full of water are none too many; and if we

have produced material shock, as evidenced by the pulse, a few pitchers of water poured through the drainage-tube and allowed to pour out again has at times, as I believe (permit me to say, I absolutely know), saved lives that otherwise would have been lost. The operator of to-day who seeks to do away with the "wash-out" and the drainage-tube on all occasions, on theoretical grounds, is rolling the wheels of progress backward. The skilful management of a patient during shock is of very great importance indeed. The use of opium to put the disturbed tissues at rest has the genuine ring of surgical wisdom. The use of strychnia to keep up the tone of the nerves distributed to the intestinal tract, and thereby counteracting the tendency to gaseous distention of the bowels, is one of the precious comforts to the anxious abdominal surgeon when his patient is low in shock.

When Ephraim McDowell made his first ovariectomy, the citizens surrounded his house threatening his life because he was about to "butcher a woman." The sheriff of the county interfered. At first they refused to listen to his pleadings for the doctor's life. Finally he struck a compromise, the mob agreeing to let the doctor alone if the woman recovered, the sheriff agreeing not to interfere if the woman died. This was a crucial test of the doctor's heroism. Other heroic surgeons for years did not hesitate to remove ovarian cysts, but allowed women to pass on to their graves if the diagnosis convinced them that it was a fibroid tumor. Still later surgeons removed fibroids if they were pear-shaped and a pedicle could be easily formed, allowing women to pass on to their graves if the examination showed the tumor deeply imbedded in the pelvis by nodular masses. Even the great and noble Dr. Thomas Keith, after battling with fibroid tumors with as good a percentage of recoveries as any one at that date, finally abandoned fibromectomy, resorting to the use of electricity, and only wished that he had back from their graves the patients that had died from his operations for fibroids. Thank God there were others to take up the work when he became discouraged. The old adage that the qualifications of a surgeon were "the head of an Apollo, the eye of an eagle, the heart of a lion and the hand of a woman," is eminently true, especially as regards him who would seek to be successful in removing fibroid tumors. The head to plan and to meet the surprises which spring on us during such work; an eye to see quickly the exact constriction of every ligature and adjustment of every suture; the lion heart to forge forward in this aggressive work when our percentage of recoveries might be better if we would let fibroids alone, especially bad ones; the nimble wit in the end of the fingers, backed by an indomitable will to skilfully and speedily perfect the last suture with the same precision as the first, make a combination of qualifications suggesting that the surgical type of a man is not to be found thirteen times in a dozen.

No operation so thoroughly demands that the trinity of surgery be carried out—thorough preparation of the patient, thorough operating, and skilful after-treatment. As American surgeons we have a right to be proud that no other nation leads us in the originality of methods or successful results in removing fibroid tumors. Almost every State of our Union has operators who would venture to give a woman with a fibroid tumor the chances of life which surgery offers. With a more thorough and perfect understanding of the

essential anatomical conditions which make an abdomen containing a fibroid tumor different from one containing an ovarian cyst, with the realization of the ideal method applicable alike to all fibroid tumors regardless of their morphology, a method as successful in the hands of the many skilled operators as the few, may we not hope to say with all sincerity that fibroid tumors can be removed with the same low rate of mortality which has placed ovariectomy among the brilliant triumphs of the century? Then shall the torch lighted by McDowell in the midnight darkness shine forth with resplendent glory in this brilliant noonday of abdominal surgery. The century which in a few years will have rolled on to the eternal past, has placed in the magnificent temple of medicine many pillars of surpassing beauty and grandeur, while its surgical columns have risen high toward Heaven, where as gilded towers, they fain would vie with the God-given sunshine in dispelling the chill and gloom of human agony.

Chirurgia's tower, thy lights resplendent blaze,
Dries woman's tears and lengthens out her days.
McDowell and Sims, of our Columbia's clime,
Began the work moved onward high sublime.
To woman then, these blessings shall be given,
Queen of the home and home the type of Heaven.

Abdominal surgery is proud of her past because it is prophetic of her future. Even now in the vital present it shall stand forth unchallenged as the crowning glory of all science and of all art.

ABSTRACT OF PRESIDENT'S ADDRESS

BEFORE THE AMERICAN LARYNGOLOGICAL SOCIETY,
AT ITS SIXTEENTH ANNUAL SESSION, WASHINGTON, D. C., MAY 30, 1894.

BY D. BRAYSON DELAVAN, M.D., NEW YORK.

In opening our Sixteenth Annual Congress let me heartily welcome you to what gives every promise of being a most useful and enjoyable meeting. The support which you have given it, both by your presence and the scientific contributions provided, has been spirited and generous; and I am assured that you will still further co-operate with me in carrying it through to a harmonious and successful close. Surely the experiences in sixteen years should give light to illuminate for us the present and enable us to look forward somewhat into the future. In trying to forecast the future it is eminently right that we should indulge in retrospect, particularly for the benefit of many who may have but recently come among us and to whom our early history may be unknown. I shall aim therefore to go back with you to the early history of this Association.

[The President then gave a detailed account of the various factors which led to the formation of the Association. Special honor was paid to the preceding work of Horace Greene, who was the pioneer specialist in this country in diseases of the throat, and whose works now prove that he led the world. He died, however, before this Association came into existence; but he left behind an able and brilliant successor in Elsberg, under whose presidency the Association was formed at Buffalo in June, 1878.]

THE SOCIETY'S AIM.

The labors of Elsberg and his contemporaries in the formation of this Society were a preconceived move-

ment in the direction of a higher and broader education, and were an intelligent and vigorous effort to advance and disseminate the knowledge of our special work. How faithfully this primal aim has been carried out our history attests by its annual meetings, publication of transactions, encouragement of special literature of our department by the bringing forward of youthful aspirants for laryngological fame, and by the practical study of the best methods of instruction in our schools. New York city was the place, the autumn of 1873 the time, and Dr. Clinton Wagner the promoter of the first society ever founded for the exclusive study of laryngology and rhinology.

[Attention was directed by the President to the formation of various special foreign societies and the vast increase in the number of organizations in this country whose attention is entirely devoted to these branches.]

It is a great satisfaction that this strong onward movement should have been headed, and at so great a distance in advance, by this country; and it is surely not unpardonable that we should in the enthusiasm of the time express ourselves as the occasion warrants. But if we are still to be an example to the world, we must still strive for superiority. The place which we have won must be held, not through vain-glory, but through increased diligence on our own part and an ever-broadening receptivity to the ideas of others.

GROWTH OF SPECIAL LITERATURE.

Our Association is intimately related also to another important educational factor. Special journals have now become quite numerous, and our own work receives a generous and constantly growing appreciation in the columns of our general medical journals. The establishment of the bibliography of the earlier laryngology was largely the work of several of our Fellows.

THE ASSOCIATION'S MOTTO.

"Docendo discimus — by teaching we learn."

If we are to reach the higher usefulness, we must ourselves be teachers. The question of education as related to our own department is by far the most opportune by which our attention could possibly be engaged. Therein lies the hope of the future as to our own reputations, and, what is still more, as to the beneficent ends to which we fondly hope our specialty may attain. The problem of instructing undergraduates may be said, in this country at least, to have been squarely met and fairly solved. One of our institutions particularly is of conceded superiority, both as to its plan of instruction, equipment and general discipline. But other schools as well are doing creditable work. All the problems, however, can never be solved by undergraduate institutions, and to meet the new needs there have sprung up the various so-called post-graduate schools. The task of the teacher in this field is more difficult, for the needs of his classes are far more varying than is the case with the undergraduate. His students are men of some experience in general practice, of a wide diversity of preliminary education; and they are frequently hampered by preconceived ideas. They often have much to unlearn before they can grasp fully the salient points as to what the science of laryngology really is; hence the greater difficulties of the teacher's task. But the theory of graduate instruction in this country is an established and triumphant success, and it may well be the province of this Association to discuss how we can best

infuse the ferment of sound learning into the unleavened but well-promising mass of students who come to our graduate schools. Three things seem demanded to bring about this desired result: first, a higher and more thorough general medical education on the part of the student; second, more careful selection in the choice of instructors; third, a modification of the best undergraduate methods to satisfy the needs of the older men.

A FINAL WORD.

When this Society was formed laryngology was in the hands of a few men, who, under the stimulating influence of the earliest enthusiasts, formed a veritable aristocracy of learning. Now it is changed. The spirit of socialism has been among us; that noble and generous socialism of science which, having acquired a rich and rare possession, desires to spread it broadcast and with lavish hand to the four quarters of the earth. The old order of things under which our specialty was held in the hands of a few has passed away.

THE OBSCURE ORIGIN AND INDETERMINATE COURSE OF ACUTE INFECTION, AS ILLUSTRATED BY A CASE OF MALIGNANT ENDOCARDITIS.¹

BY J. S. GREENE, M.D., OF DORCHESTER, MASS.

In the near past, when the theory of infection now in vogue was first authoritatively set forth in its full and fascinating proportions, it seemed as if there could no longer arise cases of doubtful nature or uncertain origin. The so-called spontaneous development of infectious maladies in man apart from any ruling epidemic was artificially paralleled by Bouchard when he provoked in healthy animals, without wounding, the rapid appearance of microbes in the blood, by the application of depressing causes such as cold, fright, fatigue.²

By the action of such commonplace influences the pathogenic bacteria which inhabit our cavities, and which ordinarily remain harmless, are enabled to penetrate into and multiply in the fluids. It is thus that infectious diseases become generalized or aggravated in the system, and set up the phenomena of septic fever.

Some of these phenomena are headache, pain in the back and limbs, secretory disturbances, coma, convulsions, delirium; and perhaps there must be added to this already formidable train, paralyzes, both of peripheral nerves and of nerves proceeding from the bulbar centres on the integrity of which the instant life depends.

We are no longer permitted, as in the beatific past, when bacteria were not in sight and ptomaines were not even suspected, to talk of brain fever when the septic process is chiefly determined to the cerebral functions, nor of rheumatic fever when the back and limbs receive the rebound from the shock of poison dealt to the trophic nerve centres. Still traces of what was our state of blissful ignorance remain, and in the light of later knowledge show as black spots on our sunshine. Cases yet arise where a disease ultimately determined to be of infectious origin masks

¹ Read before the Boston Society for Medical Observation, March 5, 1894.

² *Theorie de l'infection, verhandlungen des x internationalen congresses*, s. 1. 49.

itself behind groups of symptoms capable of being quite otherwise interpreted. The infectious agent, whatever microscopic form it takes, induces a septic fever, which acts with varying intensity and by multi-form combinations on the nervous system and on different organs and functions. Soon or late, the integrity of some important organ may be steadily invaded, or an acute inflammatory process may be localized in some tissue; and whether these complications occur or not, the phenomena of septicæmia, pure and simple, may dominate to the end. Again, the infection rather than the localization may have had the minor rôle, proceeding without the ranges of temperature commonly associated with septic processes. Nervous disturbances apparently or manifestly functional may prevail over either thermic or adynamic, to that degree that when the disease finally becomes localized by signs or symptoms ordinarily unmistakable, these signs and symptoms are misinterpreted because disconnected from their customary relationship.

Material for cultures is not always attainable during the course of the disease; and when a fatal issue has not been averted, and when the pecuniary or vital wants of survivors combine with the scientific interest of the physician to seek what of verity autopsy may reveal, the early solicitude of the funeral undertaker to preserve the integrity of the mortal remains by the injection of poisonous chemicals will probably have interposed an effectual barrier to the inquiries of the bacteriologist and the microscopist.

A fatal case of disease of infectious origin simulating multiple neuritis, but proven by autopsy to have been acute endocarditis, supplies the clinical material to illustrate the foregoing remarks.

The case was that of a man thirty-four years of age, by occupation a letter-carrier, and thus exposed to the influences of cold and fatigue. His father died of typhoid fever; his mother survives in impaired health, with signs of cardiac trouble. There is no family history of rheumatism. The patient was about five feet four inches in height, spare in flesh, nervous temperament, good habits. At the age of thirteen, after the shock of a fall and exposure to wet, he had a prolonged attack of inflammatory rheumatism with cardiac and pleuritic complications; but recovery, though slow, was complete, and for twenty years thereafter he had no illness requiring medical attention. A less satisfactory state of health dates from about a year ago, when he yielded for part of a week only to an attack of gripal influenza. Following that came annoyances of nasal catarrh and anal fissure, for which troubles he sought relief as a hospital out-patient. These ailments, and a cold pain, as he termed it, above the left hip, accompanied noticeable diminution of strength. Early last November a widowed sister living with him died after a brief illness, leaving two orphan children to his charge. Soon after this event, prodromic symptoms began, and for two months continued to accumulate. These symptoms were lessened appetite; frequent perspirations; pains in shoulders, legs and soles of feet; cold throat; stiff and tired ankles, worse in morning. His urine had been remarked habitually thick.

During the week previous to the final yielding to illness, his nights were marked by sweats, and by cold, restlessly-moving feet; and he remained in bed two days before going again upon his route. In the night of Sunday, January 14th, he aroused the family by a scream of pain, and said it was as if his two feet were

cut off. Pain lasted all night, yet he went to work Monday, but ate no dinner. While delivering, pains caught him, first in chest from side to side, passing to back of legs below knees; and he returned home with stooping shoulders and limping gait. Nevertheless, that evening he walked half a mile and back to consult a doctor, and got a tonic. Tuesday, the 16th, he put his last day's work between two restless nights. Wednesday morning, the 17th, at 3 o'clock, he arose and went down stairs, unable to rest from pains in sides and chest, in legs and in feet. That day a physician was summoned. The patient complained of stiff cords around ankles and numbness of soles. Thursday, red streaks were seen on the feet. The hands and arms had become painful, and the abdomen was hard. Friday, the jaws and the back of the neck were involved in the suffering. The history to this point is gathered from patient and his mother.

I first saw him on the evening of Saturday, January 20th, in consultation; and at the joint request of physician and patient, I became associated with the former in the guidance of the case. The patient was lying on his back, with an aspect of helpless unrest, talkative and moaning; his countenance expressive of anxiety. The pulse was 104, fair quality; respiration 26; temperature 101.2°; tongue clean, but dryish; thirst. He complained of shooting pains down the thighs and legs, of burning tenderness of the outer and inner aspects of thighs, and of numbness of the soles just anterior to the heels — all dating from Wednesday; of pains in the arms (especially about the elbows), with numbness of the two outer fingers of each hand — from Thursday; of pain in the lower jaw, below articulation on each side — since Friday; of concurrent pain about the region of the lower ribs on each side, especially the right. On examination, there was no redness nor swelling of joints nor elsewhere. The tenderness elicited by touch was regional, not following the course of large nerves nor in joints; especially noted at the upper portion of the calves and at the anterior surface of the soles, including toes, especially of right foot. Other points or patches of tenderness to touch were over the ramus of the jaw on each side. Moving or flexing the toes caused pain. There was a degree of rigidity of the lower limbs, and of resistance to passive motion, and such motion caused pain; but the pain was vaguely localized, and not in joints. Hands and arms showed less rigidity and little tenderness. He moved the jaw with difficulty, complaining of pain below articulations. It was noted that the apex beat of the heart was in the mammary line in the sixth interspace; but there was no diffused nor heaving impulse, and the heart sounds were clear, unaccompanied by murmur and of normal rhythm, and so remained throughout. The plantar and patellar reflexes were absent. Albumen was absent from the urine, which was heavy with amorphous urates. The patient lived for ten days longer, and died the 30th of January.

During this period of daily observation, there was gradual abatement of numbness, of localized tenderness, and of muscular rigidity; no restoration of tendon reflexes; muscular wasting rapid and extreme.

On the 24th, it was noted that pains had appreciably abated within two days, and none remained in sides of chest. Patient could move limbs more easily, and open jaws more readily. He still shrank from touch at the plantar surface of the toes and adjacent part of the soles, and still kept the limbs rather rigid, espe-

cially his hands and arms, with fingers spread apart, moving and flexing like one slowly scratching.

On the 25th, he sat on the edge of the bed a few minutes after passing urine.

On the 26th, there were painful and unsuccessful attempts at micturition, a resort to the catheter, and (later) successful voluntary effort. This day tenderness to touch and numbness were all gone. A few petechial spots were seen on the legs. He still kept a certain rigidity of joints on passive movements, as if fearful of hurt, but could relax and move painlessly. The type of fever became more and more distinctly typhoidal, the tongue more dry and furred; no sordes. Delirium of sufferings and of travel, active at first, became somewhat more quiet. He wandered all over the country and encountered all kinds of trouble; he never knew where he was, but was sure he was not at home, though he got almost there; yet he knew every one about him. He had occasional "wild spells," when he wanted to get up and off, but had little strength to exert. There were moments of quick, labored respiration, but not often; scarcely any cough.

His temperature had no regular oscillations, but ranged oftenest from 100.5° to 101.5°; but the morning of the 23d it reached 103.5°, and the evening of the 24th and the following morning it was 103°. The pulse generally went with the temperature, though not invariably; it varied between 104 and 120, reaching (exceptionally) 130.

The last day I did not see him; but there was choking on attempts to swallow, collapse with cold sweat, and he died with gradual heart-failure.

Dr. Wm. T. Councilman performed an autopsy, Thursday, February 1, 1894: "Anatomical diagnosis, acute endocarditis of aortic and mitral valves. Body of medium size, slightly built, somewhat emaciated. The body had been injected by an undertaker, so that little could be told of the degree of congestion, etc., of internal organs. The peritoneum was smooth, and there were no lesions in any of the abdominal organs. The spleen was large and rather soft. Both lungs slightly adherent. On section, a slight muco-purulent secretion in some of the smaller bronchi. The heart was of ordinary size, the cavity of the pericardium obliterated by adhesive pericarditis. Myocardium pale and easily torn. The valves of the right heart were normal. On the aortic valves, just along the line of closure, there were numerous projecting granulations. The valve about the seat of these vegetations was thickened. Similar vegetations were along the free edge of the mitral valve, and in one place extended over the auricular surface of the valve up to the auricle. The tissue here was thickened, infiltrated, and small ecchymoses were here and there visible. The nerves of the lower extremities were removed for examination. Owing to the injection of the undertaker, bacterial cultures which would probably have thrown much light on the case could not be made. I think there is little doubt from the character of the lesions in the heart that there has been an infection with either the *diplococcus pneumoniae* or the *streptococcus*."

The result of this autopsy was the revelation of an unsuspected seat and form of localized inflammation. True, the chief signs and symptoms on which a diagnosis of infectious neuritis was founded had gradually abated during the week which followed my introduction to the case. On the other hand, the group of symptoms representing septic infection had kept their

unrelenting sway, dominating and supplanting, while no signs were detected nor symptoms intruded to draw attention to a lesion of cardiac valves.

Thus, prior to the autopsy, there still remained the possible alternative that death was wholly due to the effect of the toxins of infection acting on the higher nerve centres. The inference that such was partly the case, that the cardiac lesions were in fact subordinate in determining the manner of death, derives support from the symptom of occasional rapid, labored breathing, and from the paralysis of muscles of deglutition noted some hours before death.

The temptation is here presented to follow to their natural conclusion these observations on the uncertainty attending the origin and course of acute infection, by some reference to like uncertainties in the fatal ending.

This final point can be illustrated by a case of possible multiple neuritis comparable to the foregoing one, but introduced here only in synopsis. It was the case of a young man of remarkably neurotic constitution by inheritance, whose father and two paternal relatives had died suddenly in acute agony — two of them with precordial pain, the third (a girl of sixteen) of toothache, so-called. An autopsy on the father showed no disease of brain, heart nor kidneys. The son had been pushed to the verge of nervous break-down by overwork and use of tobacco; still further depressed in his vitality by two illnesses supposed to be *la grippe* — one marked by semi-stupor, numbness and bad head, the other by vomiting, headache, pain of back and limbs, and rigidity.

He is out for an evening's enjoyment, perhaps gets chilled, has next morning a convulsive seizure, nearly or quite unconscious, some fever and transient albuminuria; five days of disability with spinal and lumbar pains. Another seizure; nine more days of suffering, involving legs as well as back. Another seizure; pains more torturing, and involving arms and somewhat chest, as well as back and legs. After six more days an agonizing pain in head aroused by a trivial cause; a distressful, restless, but not usually painful head throughout; and finally a sudden snap, and death after twenty-two days' illness.

No autopsy was permitted. The outset of the illness was very peculiar, some of the indications during its course equivocal, one period reassuring and thereby misleading — other periods absorbingly distressing, and the termination unexpectedly sudden.

It was undoubtedly a case of acute infection, and its phenomena can perhaps be explained either on the theory of multiple neuritis or through the action of toxins on the nerve centres, without the existence of localized microscopic lesions. What concerns us here is the question how death was induced.

In the *Revue de Médecine* of February 10, 1891, Dr. Havage, of Paris, reports a case of alleged acute infectious neuritis, in the course of which, and following the abatement of fever, there occurred numbness and pricking, and then extensive paralyses involving not only the limbs but the facial muscles and some of those concerned in articulate speech, and finally the right external muscle of the left eye, inducing strabismus and diplopia. Nevertheless, in a month from the onset of the disease recovery from these paralyses was nearly complete, and the entire restoration to health was not delayed to the end of the second month. Those who cannot share the sanguine belief of Dr. Havage that the case was one of multiple neuritis —

a belief that seems scarcely consistent with the general observation of the length of time needed to effect repair and restoration of function in nerve tracts which have been the seat of an inflammatory process — must necessarily regard these formidable paralyses as transitory effects of the toxins of infection.

If, then, such toxins can cause extensive paralyses of peripheral nerves without the aid of inflammation, there is little difficulty in perceiving how they may also, by their depressing, irritating, or paralyzing influence on nerve centres, determine death in various forms, by heart-failure, by asphyxia, and even by pain and shock. Also it is obvious how important must be the influence of family constitution and personal idiosyncrasy in shaping the fatal issue. A single sharp agony sometimes ushers in an attack of localized neuritis; and pain in the head or chest or elsewhere was a notable feature at the critical points in the history of the family to which I have referred. Was there a correlation between these two facts, or did ptomaines alone cause pain enough to kill? What changes do toxins effect in the nerve elements, to induce now lingering, and again sudden, death?

The questions may not be answered; but the asking serves its purpose of illustrating the obscurities still so often attending the termination, as well as the origin and course, of acute infection.

CRYSTALLINE DEPOSITS IN THE URINE: THEIR CAUSATION AND RELATION TO RENAL DISEASES.¹

BY EDWARD M. GREENE, A.M., M.D.

(Concluded from No. 22, p. 541.)

CASES of oxaluria and uric-acid crystals, associated with more or less dull pain in the lumbar region, are familiar to all, and require no further comment other than to emphasize the importance of a microscopical examination of urine, in order to differentiate them from lumbago, muscular strain or uterine disease. There are rare cases, however, in which there occurs a sudden precipitation in the kidneys of a large amount of crystals, causing agonizing pain fully as severe as that produced by calculus. In these cases it has been supposed that a stone was actually passed, but was not found on account of careless observation. This, I am convinced, is not always the case. I have had an opportunity to study this interesting condition in two cases, which I will relate.

Mr. R. F., a chemist, age thirty-one — pale, of a nervous temperament, rather below medium weight, but of good muscular development, of good habits, family history negative — had previously passed two life-insurance examinations, but recently had been under considerable mental strain from family troubles, and suffered considerably with dyspeptic symptoms. In August, 1891, he had been taken suddenly, for the first time, with severe pain in the abdomen and lumbar region, but recovered after one day's treatment with morphine and cathartics.

The physician who had charge of him at that time did not examine the urine, but thought that the colic was connected with constipation. In the next two months he had similar, but not very severe attacks.

I saw him first on November 19, 1891, three months

after the beginning of this trouble. The pain in this attack began while he was at work in his laboratory, and rapidly increased in severity, so that he had barely time to get home and into bed before calling me. I found him groaning apparently in intense agony, and at once gave him one-quarter of a grain of morphine hypodermically, repeating it about an hour later. Pain was most severe in the right lumbar region, extended down the abdomen in the direction of the ureter to the bladder. There was considerable pain also in the left lumbar region, and tenderness on pressure on both sides. The skin was moist and pale, and the pulse about 60. Expression was worn and anxious, and he was constantly nauseated and had severe vomiting. Morphine was continued as necessary, and the pain gradually wore off and disappeared entirely in four days. There was no increased frequency of micturition. The first urine passed after the pain began was of a high, slightly smoky color; acid; specific gravity 1.028; one-tenth per cent. of albumen; sediment considerable in amount, and consisted of considerable altered blood, excess of mucus and leucocytes, and numerous calcic-oxalate crystals. Under the use of alkalies and a large amount of water the calcic oxalate disappeared in a few hours, and the blood and albumen two or three days later.

On November 28th the urine was alkaline; specific gravity 1.025; free from albumen, blood or casts, but there was a slight increase of leucocytes and mucus. December 2d, urine was high-colored, strongly acid, specific gravity 1.027, no albumen, but a considerable sediment consisting of calcic oxalate and mucus shreds. December 5th, there was no albumen, and a few leucocytes only in the sediment. The urine was all saved and examined before being thrown away, and never contained calculi or even gravel large enough to be seen by the naked eye.

December 29th, I was summoned by a carriage to come at once to his place of business, and found him in another severe attack. He had not had time to get home, but was lying on the floor in great pain, vomiting, and almost dazed. I injected morphine subcutaneously, and drove at once with him to the Massachusetts General Hospital, where he arrived almost in a state of collapse, rolling about with the pain, in spite of one-half a grain of morphine given subcutaneously. Pain was located principally in the back, just below the twelfth rib on the right side, from which it would shoot occasionally down to the right testicle in a line corresponding with the ureter. There was less severe pain in the left loin, but both sides were tender on palpation. There was no evidence of floating kidney. Pulse was 50, small and weak, but regular. He was given one-eighth of a grain of morphine every two hours and a poultice applied. The pain became gradually less, and almost disappeared after two days. Unfortunately, the first urine passed was not preserved, and in the hospital history there is no record of the urine, except that on December 31st it is stated that the "urine shows no constant crystalline sediment." On January 9th, an examination of the urine was made by Prof. E. S. Wood, as follows: "Color normal, acid, 1.019, urea and uric acid normal, albumen very slight trace, sediment slight, and showed a few hyaline and finely granular casts, some of large diameter, probably from the straight tubules." During his stay in the hospital no calculus was found, nor any gall-stones in the stools. The pulse ranged from 50

¹ Read before the Boston Society for Medical Observation, March 5, 1894.

to 60, but during the last four days from 60 to 70, and the temperature from 98° to 99°.

As there was no evidence of stone in the kidney, he was discharged well January 9th.

I did not know the secret of the patient's mental and physical condition until he asked me to testify in divorce proceedings on July 1, 1893.

It seems that some six months before these attacks began he had married a young woman on only two weeks' acquaintance. She was a public singer, and, according to her own admission, she never once allowed her husband any sexual connection, on the ground that pregnancy would spoil her figure and hurt her voice. She slept with her husband constantly. I testified that this state of affairs had brought on neurasthenia, melancholia and dyspepsia, which predisposed to the formation of calcic oxalate, and that his constant ungratified sexual desire tended to increase the hyperæmia of the kidneys. No contest was made, and the judge granted absolute divorce.

He did not return to his wife after leaving the hospital, and never had another attack. He has also gained ten or fifteen pounds in weight, and now feels perfectly well.

The second case I had a good opportunity to watch, as he was under observation at my own house during two of his attacks. The patient was a young business man, aged twenty-nine, married, of good family and personal history, strong and well-developed, of average weight.

His first attack occurred without any previous warning at 6.30 A. M. on July 3, 1891. This pain, which was severe, was in the left lumbar region, and lasted all day. The treatment was morphia injections.

The second attack was milder, lasting only a few hours, and occurred some six or eight months later. The physician then in charge was said to have been puzzled how to account for the attacks. The third attack occurred under my observation December 3, 1892. The patient had been at work as well as usual during the day, but about the middle of the afternoon began to have a dull pain in the lumbar region. The pain gradually increased in the course of an hour, when the patient came to consult me about it.

Almost as soon as he reached the office the pain became severe, and I gave him one-eighth of a grain of morphia by the mouth. In a few minutes the pain was so severe that I gave him one-quarter of a grain of morphia subcutaneously.

This had no effect, and he was soon shrieking with pain and tossing about in agony. The skin was blanched and covered with perspiration, the pulse was 62. Pain was referred mostly to the right lumbar region over the kidney, and, to a less extent, to the region of the left kidney. The pain did not especially follow the course of the ureter, and there was no desire to micturate.

Both flanks were tender on pressure. Ether was then given and pushed to complete anæsthesia. On removing the ether after a few minutes the patient complained again, and more ether was given. In about half an hour the ether was again removed. The patient was very hilarious and happy in coming out of the ether, and said he had no pain at all.

He soon began to pass urine in large amounts. The first specimen passed after the attack was pale, acid, 1,018, albumen a slight trace (one-fifteenth per cent.), sediment considerable, and consisted of clumps

of small calcic-oxalate crystals imbedded in mucous shreds, a little blood, epithelial cells (probably from the pelvis of the kidney), and a few hyaline casts, some of which contained small calcic-oxalate crystals. The urine passed the next forenoon was perfectly normal, except for a few blood-globules.

Specimens examined occasionally for several weeks showed nothing abnormal. The entire amount of urine passed for several days after the attack was saved and examined by me, but no trace of calculus was found. In the previous attacks the patient is positive that he never passed a stone, although he watched for one constantly. There was apparently no exciting cause in this case, such as exposure to cold, over-exertion or over-eating. He never ate rhubarb.

On September 22, 1893, this patient had another similar attack. He suffered severely for nearly two hours before I could get to him and give him ether. The ether was kept up most of the time for four hours, when the pain entirely disappeared. During the next night the pain returned in a mild form for about an hour. The next forenoon he went to business at about ten o'clock, although he "felt as though he had been on a spree." The first urine passed after the pain was high-colored; specific gravity of 1,020; very slight trace of albumen; a considerable sediment, consisting of a large amount of calcic-oxalate crystals, singly and in microscopical concretions; considerable blood; and a moderate number of hyaline casts. No stone was passed, and a day or two later the urine was normal. The only cause I can find for oxaluria in this case is an habitually concentrated urine from drinking too little water. There was no evidence of floating kidney.

The treatment of these two cases during the paroxysms suggests to me the almost uselessness of morphia injections, in addition to their danger, and the remarkable success of ether in relieving the pain entirely and cutting short the attacks. The attacks in which morphia had been used were prolonged and painful.

The secret, it seems to me, is this: opium, according to Lauder Brunton, frequently lessens the quantity of urine; while, according to H. C. Wood and Brunton, ether stimulates the heart at the same time that it dilates the blood-vessels, increases very markedly the blood-pressure, and thus renders the peripheral circulation very vigorous. The abundance of urine and its low specific gravity after ether, in the second case just reported, indicate that by this means a large amount of water is at once poured through the renal tubules. Thus we get instant relief of pain and remove its cause at the same time.

The remarkable thing about these cases is the suddenness with which the crystals are precipitated and their rapid disappearance, together with albumen and blood. I have not been able to find any good account of similar cases. Dr. G. W. Allen read before the Suffolk District Medical Society in April, 1891,* a report of three cases of renal colic in which the pain exactly simulated that caused by calculi, but none were found. In his first and third cases no report as to the urine was made, and, in the second case, the urine was said to have been passed in very small amount during the attack, "not enough in all to furnish a specimen for examination, but it looked perfectly normal."

* Boston Medical and Surgical Journal, June 25, 1891.

During the next two weeks the urine was carefully examined, but nothing found to account for the attack. He was unable to make an exact diagnosis, but raised the question whether the symptoms might not be due simply to renal neuralgia.

Edes, in an article in "Pepper's System of Medicine," recognizes the possibility of the occurrence of renal colic not caused by calculi. He says: "Most physicians have seen cases when the same set of symptoms has not been followed either by the discharge of the stone per urethram or by the evidence of its continued sojourn anywhere in the urinary organs. They may occur in persons of a neuralgic tendency in connection with the uric or oxalic diathesis. If, after careful watching, no stone appears, and, on the other hand, the pain does not continue, and no pus gives evidence of pyelitis, it is highly probable that no stone is, or has been, present. A true neuralgia may undoubtedly exist."

My own opinion is that while neuralgia of the kidney is possible, that it is not a sufficient explanation for the very severe cases of sudden onset, short duration, and sudden termination. The five cases reported by myself and Dr. Allen were all in men, while it is in women that we are most likely to get neuralgia and hysterical pain. These cases I believe to be more commonly due, as Edes hints above, to irritation by crystals. In my cases it was only the first specimen passed that gave the clue to the true condition. The pain in these cases is usually in both kidneys, rather than in one, as is usually the case with calculi. It can be distinguished from the pain due to sudden obstruction of the ureter, as in movable kidney, by the fact that we get no evidence of movable kidney by palpation, by the presence of the crystals and by the occurrence of more or less pain in both kidneys. In gall-stones the pain is not exactly in the same position, and we soon get a jaundiced urine. It is a singular fact that in jaundice calcic oxalate is likely to be very largely increased. Fagge quotes Schultzen as having found as much as seven and a half grains of calcic oxalate in twenty-four hours in cases of jaundice. In other conditions which might be confounded with renal colic the onset of pain is not sufficiently sudden.

TREATMENT.

Bearing in mind the etiological factors considered above, the treatment required to prevent these crystalline deposits obviously consists in preventing the formation of uric acid and calcic oxalate in the system, and, secondly, in preventing their precipitation in the kidneys. The first result is to be gained by hygienic and dietetic measures, while the second requires medicinal treatment.

The hygienic measures consist of an out-of-door life, as far as practicable, exercise, and baths. The plethoric, high living, uric-acid victim, with his tissues crowded with waste material, evidently requires all the out-of-door exercise he can stand and warm baths to stimulate the eliminative action of the skin. The other class of debilitated, anæmic, neurasthenic subjects of uric acid or calcic oxalate are equally in need of fresh air to assist their feeble oxidizing powers, but we must be careful not to overtax their weak constitutions with too much exercise and bathing. In the consideration of diet it is especially necessary that digestion should be perfectly performed, failure in this respect causing more defective metabolism than could possibly arise

from a little more or a little less of some particular article of food.

Most persons are able to digest lean meat more easily than starchy, saccharine, or fatty substances. In the three latter classes of foods, if digestion is slow, fermentation is sure to occur and the resulting acids are taken into the blood, thus lessening its alkalinity and solvent power and interfering with all the metabolic processes. In the majority of cases, therefore, a diet containing a considerable proportion of albuminous material, supplemented by succulent vegetables, will be more easily digested than one in which the starchy and saccharine elements predominate. The diet must be carefully suited to each individual case. Stimulants of all kinds must be avoided. In cases of oxaluria we must avoid the ingestion of vegetable substances containing oxalic acid, such as tomatoes, sorrel, rhubarb, onions, turnips, cauliflower, and asparagus. The free use of pure water and of milk is extremely important. As we have already seen the urine containing crystalline deposits is almost always concentrated and highly acid. Water at the same time dilutes the urine and renders it relatively less acid.

Drinking hot water at bedtime acts very beneficially as a diuretic and gives a copious flow of urine in the morning—a point of importance, as Roberts and others have shown that uric acid is largely precipitated in the urine in the early morning hours.

The medicinal treatment to prevent the formation of crystalline deposits of uric acid differs from that required in oxaluria and will be considered separately.

We can, as pointed out by Roberts in his recent Croonian lectures, effectually prevent by medicinal treatment the occurrence of those conditions of the urine under which alone the formation of uric-acid crystals is possible. The immediate determining cause of the precipitation is excessive acidity of the urine and the essential indication of preventive treatment is to diminish the acidity.

Chemically it is impossible for uric acid to be deposited from an alkaline urine and not at all likely in a neutral or feebly acid urine. A study of the normal variation of the urine at different periods of the day and night leads to the inference that the liability to uric-acid gravel rises to a dangerous intensity only during certain limited portions of the twenty-four hours. The character of the urine has been shown by Roberts to be most affected by the digestion of food, by prolonged fasting and by sleep.

A meal, whether composed of ordinary mixed food, or of purely animal, or purely vegetable substances, produces two constant effects. It lowers the acidity of the urine and increases its volume. Conversely, prolonged fasting raises the acidity and diminishes the flow of urine. During the hours of sleep which are also hours of fasting, the acidity of the urine reaches its highest point and the flow of urine reaches its lowest point. The proportion of uric acid in the urine is highest during the time of sleep, but the hourly excretion is highest during the hours following a meal.

Obviously, therefore, the period when there is most risk of precipitation in the kidneys is during the time of sleep, and especially in the early morning, during the two or three hours before breakfast. In sleep, also, the horizontal position and the bodily repose make the urinary stream more sluggish and predispose to crystalline precipitation. On the other hand, during the day and the waking hours the recurrence of the

meals keeps the urine at a low degree of acidity, or even renders it for a time neutral or alkaline, while the renal stream is comparatively full and rapid, and its descent from the kidneys is favored by the force of gravity. It is, therefore, only during the critical period of the latter part of the night that medicinal treatment is required. In the milder cases a single full dose of one of the alkalies taken at bedtime suffices to prevent the formation of uric-acid concretions. For this purpose the citrate of potash is, perhaps, the best preparation to employ. The dose for an adult is from forty to sixty grains, dissolved in a few ounces of water. In severer cases a second but smaller dose should be taken during the night.

Haig has shown also that salicylate of soda has a decided influence in increasing the excretion of uric acid. Phosphate of soda is at the same time a good alkalizing and laxative agent. It is also, as we have seen above, the principal natural solvent of uric acid in the urine. Roberts also points out that salines exercise a protective influence against the precipitation of uric acid. People who take very large quantities of common salt with their food experience a practical immunity from stone. On the other hand, it is very frequent among the children of the poor who are fed very largely on farinaceous articles and among the natives of India who feed on rice. Acids and iron interfere with the solubility of uric acid and with its elimination.

A fact of great practical importance mentioned by Haig and quoted by Osler, is that "lithia, although a beautiful solvent of uric acid in a test-tube, yet when given by mouth never reaches the uric acid at all because it at once forms an insoluble compound with the phosphate of soda in the blood, thus removing from that fluid one of the natural solvents of uric acid and diminishing its power of holding uric acid in solution." Lithia waters, then, have been found useful because the beneficial effect of the water itself exceeds the harmful effect of the lithia contained in it. This is directly opposed to the prevalent idea of the value of the lithia compounds in the uric-acid diathesis.

For a plethoric habit the free use of alkaline mineral waters, such as Carlsbad and Vichy, is important.

In the treatment of oxaluria much less is accomplished by chemical agents. The usual tonics suitable for cases of debility are often required. Dilute mineral acids, especially nitro-muriatic acid, are considered by many as almost specifics. Their beneficial action is probably accounted for by their power to correct digestive disturbances. Phosphate and chloride of sodium have a distinct solvent action on oxalate of lime. It has also seemed to me, in a few cases, that sodium salicylate has caused the crystals to disappear.

The treatment of calculus in the kidney will not be considered here, as the so-called "solvent" remedies have been found entirely unreliable, and the final resort must be to surgical methods.

LORD ROSEBERRY ON LANDSCAPE ADVERTISING.
—Lord Roseberry, amid the cares of office, has yet been moved to ask: "What is to become of our English landscape if it is to be simply a sanitary or advertising appliance? Think of the feelings of the illustrious Turner, if he returned to life, to see the luggers and the coasting ships which he made so glorious in his paintings converted into a simple vehicle for the advertisement of a quack medicine."

BOSTON SOCIETY FOR MEDICAL OBSERVATION.

J. G. MUMFORD, M.D., SECRETARY.

REGULAR Meeting, Monday, March 5, 1894, DR. J. FOSTER BUSH in the chair.

DR. J. S. GREENE read a paper on

THE OBSCURE ORIGIN AND INDETERMINATE COURSE OF ACUTE INFECTION, AS ILLUSTRATED BY A CASE OF MALIGNANT ENDOCARDITIS.¹

DR. PUTNAM: I have been very much interested in Dr. Greene's case. It is a very striking one, and the account he gives opens a great many questions which we all wish with him we were better able to discuss. Some years ago I had a case similar to this in some respects. It was a case of infection causing death in one week or a little more and with lesions of parenchymatous neuritis. The patient had difficulty in swallowing and then difficulty in breathing, before his death. The patient was a man of nervous temperament, otherwise in good health, but had weakened himself very much by excessive sexual intercourse. Otherwise there was no apparent cause for the disease, except that he rode home one night in a open horse-car and was exposed to a severe wetting and chilling. The symptoms came on that night, and he died at the end of ten days. It is rather unfortunate that the discoveries which we make in pathology sometimes chain our knowledge and even our imagination to a considerable degree. We felt we had learned a great deal when multiple neuritis was first discovered, and when the cases began to pour in they seemed to be covered by that term; but, as a matter of fact, as Dr. Greene has pointed out, I think when it comes to a case of rapid death of that sort, the term multiple neuritis, even where we can establish the existence of manifest changes in the peripheral nerves, is often inadequate to cover the whole condition which is present. In my case there was a considerable amount of parenchymatous degeneration, swelling of axis cylinders, and great injection, with escape of leucocytes into the surrounding tissue in the nerves, and a few changes of the muscle. I examined the diaphragm and the phrenic nerve with considerable care; and although changes were present there, it did not seem as if that could have been sufficient for death. It seems more probable that death was due to poisoning of the nervous centres; and in my case that was in a measure borne out by the discovery of changes at the root of the vagus nerve, although there was nothing in the actual nucleus of the vagus which could be called pathological as far as I could tell. I should think it might be still open to doubt whether in Dr. Greene's case there may not possibly have been alterations in the peripheral nerves, for the reason that these alterations sometimes occur at the very extremity of the nerve and not in their course or at the roots. The question of the cause of death in these cases is very interesting; and, as far as I know, the bacteriologists do not pretend to say why patients with diphtheria die, or why patients with tubercular meningitis die. The information at our disposal seems inadequate to account for the result. In an interesting disease more or less allied to one of the many forms of multiple neuritis, — acute ascending

¹ See page of the 557 Journal.

paralysis — the patients apparently die from some poison before the changes are established in any portion of the nervous centres, so far as we are able to detect them.

DR. ERNST: I have but little to say. Of course, from the scientific point of view it would be well for some protest to be entered against the immediate injection of cases where autopsy is likely to be held, because it is not uncommon that the ultimate examination is very much injured by the preparations of undertakers.

DR. E. M. GREENE read a paper entitled,

CRYSTALLINE DEPOSITS IN THE URINE, THEIR OCCURRENCE AND SIGNIFICANCE.²

DR. PUTNAM: I should like to ask whether the high specific gravity generally indicates increase of the total solids, and also whether Dr. Greene can throw any light on the controversy with regard to the symptoms of the uric-acid diathesis?

DR. GREENE: The high specific gravity was indicative of diminution in the amount of water. I did not consider the subject of uric-acid diathesis, on account of the length of the paper. Uric acid has been injected into animals without doing harm. I have seen the explanation where there were severe headache and uric acid, that it was similar to precipitation in the joint, precipitation in the meninges of the brain — a mechanical cause and not uric acid in solution.

DR. AYER: I should like to ask Dr. Greene in regard to the effect of irritation of oxalate of lime or uric acid upon the kidneys, as he states that some authors are of the opinion that it may cause chronic nephritis of serious character. I wonder if he has followed along cases to be certain of that. I have been following five or six years a case where the irritation of the kidneys was probably started by a renal calculus, and since then the urine has generally contained quite a trace of albumen, with casts of different kinds, and almost always oxalate of lime. The patient is no worse. I have been puzzled to know whether it was chronic nephritis or a persistent irritation from oxalate of lime and uric-acid crystals, which might continue many years and be of no consequence.

DR. GREENE: The points I brought out in my paper were chiefly these, that constant irritation of the kidney, producing hyperæmia with blood in the urine and albumen, must do harm if kept up long. I have not been able to follow any case long enough to see it run into a chronic interstitial nephritis. That is a condition which may go on years and years. I know of one case in which a considerable amount of albumen and casts has been present ten or twelve years, and the woman has had several children without bad effect.

AMERICAN SURGICAL ASSOCIATION.

ANNUAL MEETING, WASHINGTON, D. C., MAY 29, 30, 31 AND JUNE 1, 1894.

FIRST DAY. — TUESDAY.

THE Association was called to order by the President, DR. J. EWING, of Philadelphia, who delivered the

PRESIDENT'S ADDRESS.

In this was considered only matter of interest to the Fellows of the Association, referring to the previous work of the Association, and the method of best carry-

² See page 560 of the Journal.

ing on the work of the Society. The Secretary, Dr. J. R. Weist, presented, for the President, the Association with a gavel which had been made from a portion of the office chair of Prof. S. D. Gross, the founder of the Association. This was accepted with the thanks of the Association.

The first paper was entitled

THE SURGICAL TREATMENT OF EMPYEMA,

by JOHN ASHHURST, JR., M.D., of Philadelphia.

The following summary was presented:

(1) No operation is justifiable unless the presence of pus is certain; unless thorough treatment by medicinal agents, blisters, etc., has failed; or unless the symptoms, dyspnoea, etc., are so urgent as to demand immediate relief.

(2) The first operation should consist of simple aspiration, with antiseptic precautions.

(3) When the fluid has partially reaccumulated, as it almost certainly will do, if purulent, incision and drainage should be practised.

(4) Drainage is best effected by making two openings, one at the lowest point, and carrying a large drainage-tube through the cavity from one opening to the other.

(5) Drainage should be supplemented by washing out the cavity with mild antiseptic fluids; when the lung has expanded and the discharge has nearly ceased, the tube should be shortened, the upper opening being allowed to heal, and the tube then being gradually withdrawn through the lower opening.

(6) When the lung is so bound down by adhesions that it cannot expand, resection of two or more ribs should be practised (Estlander's operation, so-called), in order to allow collapse of the chest-wall and to promote healing by bringing the costal and visceral layers of the pleura into contact.

(7) The more extensive operations of Schede and Tillmans, while probably justifiable in exceptional cases, are not to be recommended for general employment.

DR. CHAS. B. NANCREDÉ, of Ann Arbor, did not see the advisability in cases where pus was shown to be present by aspiration, of limiting the treatment to this operation. It is held that in a few cases this will be followed by cure, but he had never seen such a case. Where pus is present, he preferred to immediately provide for its permanent evacuation. He called attention to the danger of the drainage-tube becoming occluded by the pressure of the ribs, and he believed that in empyema of long standing some form of excision of the ribs should be employed.

In irrigation, if the pus is not too much contaminated, sterilized water is sufficient; but, if necessary, an efficient antiseptic solution may be used, and if there is fear of absorption, the chest can afterwards be flushed with sterilized water.

If provision is made for the free escape of pus, he had seen no necessity for the removal of large segments of ribs.

DR. T. F. PREWITT, of St. Louis, thought that the rule that no operation is justifiable unless the presence of pus is certain, needed modification. As a rule, we can determine only that fluid is present and cannot be sure that it is pus. He thought it advisable to aspirate even when serous fluid is present. If thorough antiseptics is maintained, this can do no harm. He had never seen it result in the formation of pus, and this

method greatly shortens the duration of the disease. In empyema in children he had seen several recoveries follow aspiration, but never in adults. In children the pus does not seem to possess that thick clotting character so common in adults, and which requires a free opening. In empyema in adults he invariably resects a rib, sometimes two ribs.

Attention was called to the great necessity of caution in the administration of anesthetics in cases of this affection.

As to washing out the cavity, he always does that, using a weak solution of bichloride of mercury.

DR. DEFOREST WILLARD, of Philadelphia: It seemed to him that the whole question was one of thorough drainage of an abscess cavity. Whether or not the ribs should be excised was to be determined by the question of securing free drainage. In children the ribs were so close together that removal of a portion of the ribs was usually required.

In the early treatment he favored the use of a clean aspirator rather than to compel nature to cause the absorption of a large quantity of fluid. Such operation did no harm and saved several weeks in time.

He believed that washing, as a routine measure, did more harm than good. If the pus was decomposed it indicated that freer drainage was needed. If strong antiseptic solutions were employed there was danger of renewed inflammation.

DR. JOHN E. OWENS, of Chicago, called attention to the necessity, when evacuating pus from the chest or washing out the pleural cavity, of changing the position of the patient during the process, in order that all the pus might be removed.

DR. CHRISTIAN FENGER, of Chicago, considered that there were certain cases in which Schede's operation was required. Its place was after milder measures such as incision, drainage, and Estlander's operation. He reported a successful cure where this operation was performed after other measures had been resorted to during seven years.

DR. ROSWELL PARK, of Buffalo, N. Y., thought that the treatment of empyema should be based upon the same principles as are applicable to other abscesses. In acute cases, where we have to deal with streptococcus and staphylococcus forms of suppuration, it may be sufficient in a few instances to simply aspirate. A large proportion of cases of empyema, however, are essentially cold abscesses, — tubercular abscesses. In these cases free incision, free drainage and excision of a rib is required. In certain cases he had resorted to scraping with the sharp spoon, and in some had cauterized the diseased surface with a fifty-per-cent. solution of chloride of zinc. He reported several cases where death would have occurred had it not been for some such radical operation.

DR. W. H. CARMALT, of New Haven, Conn., asked how far it was justifiable to go in the way of resection of ribs in these cases. He reported a recent case in which he had removed portions of five ribs, the longer piece excised being four and a half inches. In these cases it was necessary to remove enough of the chest wall to permit of obliteration of the cavity. He had also used the sharp spoon in order to secure a fresh surface.

DR. M. H. RICHARDSON, of Boston, Mass., said that the questions that arose in the treatment of empyema were different from those in ordinary abscess, for in the former we have an abscess with rigid walls.

With regard to drainage, he had used double tubes provided with valves, but considered them inapplicable and liable to cause increased trouble, for when air or pus is forced out through the tubes by coughing, a vacuum is established and the valve is held against the chest wall, preventing drainage. He believed that Estlander's operation was applicable only to certain forms of cavity, and that there were certain cases where the cavity involved a large portion of the thorax. The operation of Schede is the only one applicable after a failure of Estlander's operation.

DR. STEPHEN F. WEEKS, of Portland, Me., thought that the rule of Dr. Ashhurst, to aspirate, especially in children, was a good one. Sometimes that will result in cure. The tuberculous cavity is to be treated differently from the cavity where this condition does not exist. Thorough drainage is sufficient in many cases. He called especial attention to drainage by packing the cavity with sterilized gauze. In twenty-four hours he removed the gauze and washed out the cavity.

DR. L. McLANE TIFFANY, of Baltimore, Md., considered that the treatment of acute empyema was of more importance than that of the chronic form as it was the more common. The most important point as bearing upon treatment and prognosis was the character of the pus and its bacterial cause. The reason that the child's empyema often yields to aspiration was that in many of these cases the pus was simply a pure culture of the pneumococcus. In the adult we rarely have the pneumococcus form. Here we had a mixed infection. If the empyema was of the amoebic form the patient died. If empyema was due to the streptococcus, the odor was offensive and the cavity needed to be carefully washed out. If empyema was due to the staphylococcus, washing out was not required. Where there was time he preferred to withdraw some of the fluid with the hypodermic syringe and have it submitted to bacteriological examination.

While he used ether in general work, in these cases he preferred the use of a few whiffs of chloroform which appeared in these cases to have a peculiarly happy effect. Only a very small quantity was employed.

The employment of respiratory gymnastics was of much benefit in favoring the expansion of the contracted lung.

DR. JAMES MCFADDEN GASTON, of Atlanta, Ga., referred to the natural tendency of the empyemic cavity to open spontaneously in the anterior part of the chest. He reported two cases in which this spontaneous opening had occurred, followed by recovery.

W. W. KEEN, M.D., of Philadelphia, read a paper on

AMPUTATION OF THE ENTIRE UPPER EXTREMITY (INCLUDING THE SCAPULA AND CLAVICLE) AND OF THE ARM AT THE SHOULDER-JOINT,

with especial reference to methods of controlling hæmorrhage, with the report of one case of the former amputation and four of the latter.

In this paper were considered, first, those amputations which allow of simple disarticulation at the shoulder-joint itself; second, those cases in which the axilla is invaded, yet only to such an extent as to allow of its being thoroughly cleaned out, followed by amputation at the shoulder; and, third, those in which removal of the entire upper extremity, including the scapula and clavicle, is required.

Simple amputation at the shoulder-joint. — Here the

control of hæmorrhage is the key to the situation. The methods for the prevention of hæmorrhage are, first, those applicable to the subclavian vessels; and, second, those applicable to the axillary.

Most text-books recommend compression of the subclavian by the thumb or a well-padded key. Dr. Allis has modified this method by substituting a stick eighteen inches in length, with a pad of sterilized gauze at its extremity. This pad obviates the danger of slipping, and can be applied without fatigue on the part of the operator. The author had suggested compression by means of a solid pad held in position by an Esmarch bandage passing over the perineum; but on trial in the case of a child, this had proven unsatisfactory. A third plan consists in ligation of the subclavian artery. This is objectionable on account of the prolongation of the operation, also on account of the necessity of resecting the clavicle in order to ligate the vein, and if the vein is not ligated there is danger of the entrance of air.

The axillary methods are, first, those in use prior to the introduction of Esmarch's tubing, and, second, the different methods of using Esmarch's tubing.

Under the first head we have: (a) compression of the inferior flap by the fingers, which seize the vessels before they are cut; (b) Harvey's method, by compression of the vessels by means of a padded ruler thrust into the axilla; (c) ligation or seizure of the vessels with hæmostatic forceps before they are cut; (d) Gross's compressor (but practically this is never used); (e) Furneaux Jordan's method, by making a circular amputation at the surgical neck, securing the vessels as in a hip-joint amputation, the blood-vessels having been compressed by an Esmarch band or other method, followed by disarticulation of the upper end of the humerus.

Under the second head are:

(a) After making the antero-external flap, a stout pin is passed through the postero-internal flap between the vessels and the bone, and elastic tubing wound over the ends of the pin. In this method there is danger of the vessels retracting above the constricting band.

(b) Esmarch's method, in which an elastic tube is placed in the axilla and drawn tight over the shoulder, where it is grasped by the hand of an assistant. This is open to the danger of slipping of the bandage after disarticulation of the bone.

(c) Morre's method. In this method the tubing is applied as in the Esmarch method, but is held in place by a bandage passing around the chest and under the tubing in front and behind.

(d) Wyeth's method, by pins and elastic tubing. In this method the operation is performed as follows: The arm is held at a right angle to the body. The sharp-pointed cylindrical pins, eleven inches long and one-fourth of an inch in diameter, are used. The anterior pin is introduced through the middle of the anterior axillary fold at a point a little nearer the body than what may be called the centre of the fold transversely. The point of emergence is of much greater importance than the point of insertion; this should be one inch within the tip of the acromion. The second pin is introduced at a corresponding point through the posterior-axillary fold, emerging an inch within the tip of the acromion. The point of emergence is of importance, for if the pin emerges near or at the tip of the acromion, the moment the head of the humerus

is removed, the tubing is apt to slip downward and compress the two flaps against each other, thus hiding the cavity and permitting the vessels to retract. The pins being in position, a piece of rubber tubing is wound around the axilla and shoulder on the higher side of the pins. The disarticulation having been effected, the main vessels and all visible vessels are tied and the tubing removed, the vessels spurting being grasped with hæmostatic forceps. The author considered this the most satisfactory method of controlling hæmorrhage, and he felt confident that any one who adopted it would abandon all other methods in its favor, except possibly in emergency cases.

Amputation at the shoulder-joint in cases in which the axilla is invaded so high that Wyeth's pins cannot be used.—In 1812, Dalpech proposed to make "an oblique incision extending from the external third of the clavicle to an inch above the inferior border of the great pectoral muscle. We thus discover, and can cut near to its origin on the coracoid process of the scapula, the lesser pectoral. The index finger is then carried through the cellular tissue along the serratus magnus, then the subscapular, and is used as a hook in order to draw outward the mass of vessels and nerves. The artery is found in the anterior portion of this mass." The artery and vein are then ligated. The advantages of this method are that it gives wide access to the axilla; that we can determine with ease how far and how great is the invasion of the axilla, and if thought advisable, the operation can be abandoned at this point, or if it is decided to proceed with the operation, the incision already made serves as the inner part of the deltoid incision. The author had employed this method with great satisfaction in a case where a sarcoma of great size had invaded the axilla nearly to the clavicle.

Control of hæmorrhage in cases in which it is necessary to remove the arm, the scapula and the clavicle.—The methods which have been employed in these cases have been the following: (1) Simple compression of the subclavian artery. (2) Compression of the artery after resection of the clavicle. (3) Ligation of the subclavian prior to beginning the amputation. (4) Resection of the middle half of the clavicle and ligation of the subclavian. (5) Wyeth first tied the artery, then formed his flaps; and when the arm, clavicle and scapula were only connected with the trunk by the veins and nerves, secured the veins and cut the nerves. (6) The artery and vein have both been tied after resection of the middle portion of the clavicle. This seems to be by far the preferable method. The advantages of this method are that it prevents hæmorrhage from division of the axillary and its branches, diminishes the amount of blood lost during the operation, prevents the entrance of air into the veins, permits of a large opening of the space between the upper extremity and the chest, and enables us to divide the posterior attachments of the upper extremity, where the arterial circulation is still going on, at the end of the operation.

As a rule, recovery from this operation follows in from two to three weeks. The mortality in the more recent operations has been extremely low, one in fourteen. Again, by this method we can often amputate wide of the disease, in consequence of the relative smallness of the flaps required. In view of these facts, the author urged that in all cases of malignant disease of the upper end of the humerus, or even of the lower end when it is already diffused, we should not content

ourselves with mere amputation at the shoulder-joint, but should at the same time extirpate the scapula and clavicle.

The author reported a case in which the arm, scapula and clavicle were removed for myeloid sarcoma, occurring in a woman aged twenty years. The operation was done November 29, 1893. The patient recovered, and is still perfectly well.

DR. ROSWELL PARK, of Buffalo, N. Y., said that he had had two cases of total removal of the upper extremity, both which had been successful. One was for railroad injury and the other for extensive epitheliomatous ulcer. In the first case the clavicle was already broken, and the subclavian vessels were secured at the point of fracture. In the second case the clavicle was divided and the vessels tied.

DR. CHARLES B. PORTER, of Boston, Mass., as an illustration of the rapidity with which a malignant disease may advance, reported the case of a patient with sarcoma of the radius where the arm was amputated above the elbow. The disease soon recurred, and amputation at the shoulder-joint was made; and again the disease (sarcoma) recurred so high up that no operation could be employed. The whole history of the case extended over only one year after the first operation. A case was also reported where the arm had been torn off in a railroad accident, where he had subsequently removed the scapula and outer portion of the clavicle by an osteoplastic resection, and the wound was closed by skin grafts. Three months later a hard plate of bone had formed, very similar in shape to the scapula.

DR. JOHN ASHHURST, JR., of Philadelphia, said that he had once used the Wyeth pins satisfactorily in an amputation at the shoulder-joint. Another device to which he had resorted in several cases was to make the incision in the lower flap from without inwards, and secure the vessels in the wound.

(To be continued.)

CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

THIRD TRIENNIAL MEETING, WASHINGTON, D. C.,
MAY 29, 30, 31 AND JUNE 1, 1894.

GENERAL SESSIONS.

TUESDAY AFTERNOON, MAY 29TH.

The Congress was opened with a brief address by DR. LANDON CARTER GRAY, of New York, Chairman of the Executive Committee. Dr. Gray then introduced the President of the Congress, DR. ALFRED L. LOOMIS, of New York, who in a few remarks thanked the Congress for the honor that it had conferred upon him by electing him to the presidency; but as the time allotted to the session was so short, he refrained from making any extensive address.

This session was under the direction of the Association of American Anatomists, and the subject selected for consideration was

MORPHOLOGY AS A FACTOR IN THE STUDY OF DISEASE.

The discussion was opened by DR. HARRISON ALLEN, of Philadelphia.

It has often been asserted that anatomy is a finished subject, that nothing new can be said of it; but no true anatomist would be content for a moment with a

science thus limited. The science of anatomy is awaiting important advances to be brought about by new readings in the infinite book of Nature. The anatomical text-book assumes an ideal which is properly described. The facts that exceed this ideal or otherwise disturb it are ignored unless they are needed by the surgeon. Three sciences have appeared since the days of Vesalius and of Hunter, sciences so vast as to command the time and energy of distinct bands of workers. These are histology, embryology and general morphology, the most important of the three. Morphology is anatomy writ large. Within it is to be placed the subject of descriptive anatomy as a conventional and unimportant part. The author regretted that anatomy was still taught pretty much as it was a century ago. The demands of the surgeon still dominate the lecture-hall. The forces for the education of the medical scholar are unused; the powers of observation of the practising physician are not stimulated; the outlines of methods by which the science of morphology can be extended, unthought of; while the opportunities of accumulating at the hands of physicians, materials to be used in the explanation of phenomena of organic structure acting perversely, or serving as the causes of diseased action, are neglected. While such knowledge is in the possession of advanced clinical workers it has been obtained after their academic education has been completed. Is it not entirely proper that they should be carefully educated in these points before graduation? Empirical knowledge never leads to true conceptions. Diseases are not related to one another but to their causes. Etiology is the single factor that yields conditions which can correlate. Tissue changes furnish truer guides than function changes. In medicine, elaborate experimentation combined with anatomical observations on the dead, are worth all that is possible from empirical observations on the living. The physician should refer more problems than he is inclined to do to the morphologist.

Reference was then made to the chemical conditions that underlie texture and this was illustrated by the growth of the teeth particularly as influenced by gout.

In like manner the nails show the effect of the gouty diathesis. If among wild animals varieties were found to vary as much among themselves as do gouty and non-gouty persons, zoologists would be justified in defining therefrom subspecies. Why should not gout be defined as well by the results of the chemical compositions of the fluids as by these compositions themselves. Morphological data are the most reliable.

So long as we study diseases as distinguished from their causes and effects, we are empirical. The theories of the humorists, the solidists, or any one of the many theories which have agitated the profession would have been impossible had the system of medicine been broadly based on morphological data.

The changes in the shape and composition of a part of an organism constitute a variation, and the detection of these variations and the propositions on which they are based, constitute one of the chief occupations of the morphologist.

The value of minute knowledge of muscle fibres was illustrated by reference to the causation of œsophageal pouch and heart-failure.

In an exact sense, the structure of an animal may be said to express the resultants of certain forces. In a sense less exact, the work of the anatomist can be said to be that of analyzing the results of these forces.

Disease in a morphological sense is the expression of forces operating inordinately or eccentrically, but yet our systems completely fail when we attempt to explain them by the tests of nutrition or of heredity. The reason of this lies in the inadequacy of knowledge of the causes of which structures are simply the effects. In the study of anatomy it is not so much the fact as the import of the fact that is essential.

The author called attention to the fact that the anatomical material coming under our observation is almost always that of a highly domesticated nature and that in order to study it with advantage we must recall what is in common between man and the animals (both in a wild and domesticated state) about him. Our acquaintance with man as a domesticated animal, as a degenerate animal, and our ignorance of him as a wild and primitive animal, causes the morphologist to regard human structure with the same sort of interest as the botanist entertains for those plants which have been cultivated so long that he has lost knowledge of the typical form of the species. Can the anatomy of such an animal be said to be closed?

Degeneration while a phase of specialization, is one which portrays structures that fail to subserve the highest possible use in the economy. Illustrations were drawn from alterations in the shape of the crown of the teeth and also from the phenomena of polycuspation in the molars. Reference was also made to the proportionate size of the face as compared with the brain-case. The short-faced specimens of the skull of civilized man are the result of some profound impression on the nutritive forces rather than a reversion brought about by natural selection.

To what extent structures which are degenerate become on that account predisposed to disease it is difficult to say, but taken as a whole the animal economy resists the inroads of disease in proportion as its vitalities are maintained at high levels of efficiency. It may be asserted without fear of contradiction that the skeleton of civilized man differs from the skeleton of uncivilized man. In the crania of the wilder types of man, there is usually a disposition for one part of the skull to be in harmony with another part. This is largely absent in civilized types.

Perhaps the best single conclusion to be drawn from the study of morphology as a factor in the study of disease, is its value to humanity. The scientific study of race in connection with diseased action is almost an unbroken field. When this comparative phase of anatomy shall have been formulated, we shall for the first time have a reasonable hope that the subject of human acclimatization, the geographical study of diseases, the causes and motives of migration, and thus indirectly, the history and destiny of man himself, may be in shape for elucidation.

He was followed by DR. THOS. DWIGHT, of Boston.

Dr. Allen defines morphology as anatomy writ large. The underlying idea of his paper is to plead for a longer, broader, deeper course in anatomy. The tendinous heart-strings of every anatomist will vibrate in sympathy, producing a chorus of musical murmurs. Perchance in some of us one of the factors will be the moderator band of the ruminant which has left its normal place near the apex of the human heart to cross near the middle of the right ventricle. The expert auscultator can recognize this cord. It is good for his patient that he should know from anatomy that have these things pointed out rather than pursued. I

such a band may be present and that its sound is no sign of even functional disturbance. The ophthalmologist is none the worse that embryology teaches him the whereabouts of the hyaloid artery which may persist throughout life. Anomalies, therefore, as well as slighter variations are of practical importance. The surgeon needs to know of the fibrous or muscular band which may cross the axillary artery, that the brachial artery may divide high up the arm (very rarely in the lower third), and that the diverging artery, be it radial or ulnar, almost always runs superficially. A third trochanter, which seems much larger than it is, when felt through the soft parts, must not be mistaken for an exostosis, nor a deltoid tubercle of the clavicle for an old fracture.

Before removing the kidney, the surgeon will do well to be sure that it is not the only one. I, myself, within a few months have seen a case of complete absence of one kidney, the other being of about the usual size and in its proper place.

But it is not necessary to turn to anomalies to support the need of a deeper knowledge of anatomy for the practitioner. The statics and mechanics of the skeleton, the action of the muscles are becoming daily more important to the orthopædic surgeon and to the neurologist.

The anatomy of childhood is still almost in its infancy. Though not quite helpless it has not yet made its way into text-books, but hides itself bashfully in scattered papers and monographs. A more thorough knowledge would be of great value to the practitioner in children's diseases. How interesting and how practical in view of infant feeding is the story of the rate of growth of the stomach in the first months of life, and how few know it.

My views of the esteem in which anatomy is held are far less pessimistic than Dr. Allen's. It is but too true that we have many in high places absolutely ignorant of anatomy themselves, who look on its progress with a jealous aversion, but they are mostly on the wrong side of fifty, and they belong to a school of thought that is doomed. On the other hand, I look with confidence to the rising lights. I see in the better class of our young practitioners, a great respect for anatomy. They have a clearer vision of its sphere. One of the most gratifying incidents of my professional life is the constantly increasing number of those who come to me for information on anatomical problems or for the means of solving them.

Surely, from what I have said, I shall not be suspected of indifference to the cause if I do not quite agree with Dr. Allen as to the remedy. He would have students thoroughly instructed in the highest anatomy before graduation. I reply that there is no time. As a practitioner myself of twenty-five years' standing, I am appalled at the amount of knowledge of all kinds which is now necessary for the simplest practice of the profession by any one who would not fall behind his colleagues. I heartily agree with Buxley's saying, that any one who adds one tittle that is unnecessary to medical education, is guilty of a very grave offence. I would leave the matter to the good judgment and tact of the professor of anatomy. While his teaching should be eminently practical in the ordinary sense of the word, I would have him incidentally point out the explanations of structures from comparative anatomy and embryology, and still more insist upon the application of morphology to disease. But I would

would have him show the possibilities of anatomy which unfortunately are impossibilities in the regular course. Thus he will enlarge the student's horizon. It is not necessary to have followed a certain line of research to know that it gives promise of great results. The mind of a student so trained will be in a very different state from that of his comrade who has been crammed with facts from a compendium. Advanced students and graduates are those to whom the highest anatomy will be most profitable, and the more so that they can see for themselves its value, which the beginner must take on trust.

DR. F. BAKER, of Georgetown, D. C., spoke next.

The study of the human organism, of its structure, its functions, its diseases, of the effects that various agents have upon it, therapeutically and otherwise, must necessarily be a study of life and its manifestations; it is a biological science. The study of morphology as a preliminary to the study of disease is a necessity. The great impulse given to the study of anatomy by Vesalius and his followers in the 16th century has not yet exhausted itself. The error in the Vesalian anatomy which has prevailed up to the present time consists in considering the body as an essentially fixed organism. From this view arises the notion that anatomy is a fixed science, but even a cursory view of the history of the science shows this assumption to be baseless. To the modern biologist the human body is by no means fixed and invariable.

The human body has been studied far more than any other organic form. There is no lack of knowledge of details, but for the ordinary student these details are not classified and arranged as the results and sequences of morphological laws. It may even be said that inflammation itself cannot be properly understood without a knowledge of the morphological character of the tissues involved. The whole subject of tumors has, since the investigations of Virchow, been studied from a morphological standpoint, and it has become evident that in order to understand their causes and their history, we must know more about the laws that control cell formation and the growth of tissues.

The human body is built up of cells, and the gross variations in form must depend upon these minute cell activities. These variations may be of all grades. The morphologist studies these variations as indicating slow modifications of the form of the human body. It is well known that the body of man is slowly changing, that adaptations are going on within slowly fitting it more and more to its environment. In this process there are constantly left structures which have ceased to be of value and may properly be termed vestigial. Among such may be noted the vermiform appendix, Meckel's diverticulum of the intestine, the thyroglossal duct, hypospadias and the persistence of the choroidal fissure of the eye producing coloboma.

The erect position of the human body was gradually acquired, and in many respects the body has not yet become perfectly adapted to this posture. The shape of the pelvis has necessarily become modified that it may support the weight of the viscera, yet with all this, that weight is often a cause of hernia. As a result of these changes the pelvis of the civilized woman is less adapted for easy parturition than that of her savage grandmother of the Stone Age. Many of the abdominal viscera show signs of maladaptation. The cæcum and ascending colon are not favorably situated. The liver, instead of being supported from the spine, is

slung from the diaphragm, which to support the weight must receive strong connections from the pericardium and the fascia which supports the heart. This must interfere with the growth and expansion of the lungs. The heart itself works at great mechanical disadvantage. The valves of the veins are not adapted to the erect posture.

As the science progresses there is no doubt that many important generalizations will be made. Some, already, seem almost ready for statement. Among those may be mentioned what may be called the law of stability. It is this: that the stability of a structure varies directly according to the time it has been functionally active in the ascending series of animal life. The structures most readily attacked by disease are those at either end of the scale of activity. The original elementary tissues, epithelium and connective-tissue are the most stable, their derivations, nerve-tissue, muscle-tissue, glandular-tissue are the least stable.

Morphology is throwing light upon a vast variety of subjects connected with the domain of medicine, not only upon the causes of disease, but upon the action of cells, the problems of therapeutics, the very springs of life that underlie heredity, development, training and education. It is a growing science, one that is destined to a great future, promising much for the elucidation of the highest problems of medicine.

DR. BURT G. WILDER, of Ithaca, N. Y., regretted that he had been unable to prepare a formal paper, but he wished to express his agreement with the statement of Dr. Baker, that the human body is not to be regarded as a completed structure. It is by no means completed. The physician should consider very seriously whether it is not his duty to improve the human body in the direction in which it has been moving, namely, by the obliteration of that most frequent source of trouble, the appendix of the intestine. It is the unanimous consensus of opinion among surgeons that the removal of the appendix, if not gangrenous, presents no great likelihood of mortality. It is now four years since he proposed that we should not only do vaccination but also de-appendicize the child at a period of life when time was not very valuable, and thus improve his chances of existence.

Dr. Dwight had alluded to the impossibility of putting more into the curriculum of the schools, and to this the speaker partly agreed; but he held that there should be more morphology taught in the preliminary school education, and he predicted that it would not be many years before most children prior to leaving the ordinary college will know as much anatomy, physiology and morphology in the broad sense as can now be obtained by the average physician.

WEDNESDAY AFTERNOON, MAY 30TH.

The first portion of the session was under the charge of the American Climatological Association. The subject discussed was

SEWER GAS.

DR. ALEXANDER C. ABBOTT, of Philadelphia, presented the first paper, entitled,

CHEMICAL, PHYSICAL AND BACTERIOLOGICAL STUDIES OF AIR OVER DECOMPOSING SURFACES, WITH ESPECIAL REFERENCE TO THEIR APPLICATION TO THE AIR OF SEWERS.

A study of the literature of this subject leaves the impression that many of the opinions advanced are not

based on exact methods of investigation. We are now tolerably well acquainted with the nature of the air of sewers, and we know that as ordinarily found it does not differ conspicuously from the air that we are accustomed to breathe. Studies in bacteriology demonstrate the comparative poverty of sewer gas in bacteria. The general impression is that the air of sewers is under an active pressure and tends to force its way into houses, but numerous experiments with pressure gauges show that such is not the case. The studies upon the chemical, bacteriological and physical side of the subject, together with observations on the health of those constantly exposed to the emanations of sewage, are not of a nature to warrant the opinion that sewer air is the dangerous factor that some believe it to be. There does not seem to be a single conclusive demonstration that the air of sewers stand in causal relation to the diseases for which it has been held accountable.

Among the problems which the author had endeavored to solve experimentally in the laboratory was whether or not it was possible to demonstrate on animals that the gases arising from sewage or from other decomposing substances, have any direct effect upon the health of the animal or its ability to resist infection. The method of experimentation was given in detail. The teaching that because materials containing organisms capable of producing disease are constantly gaining access to the sewers, the air of these sewers must of necessity also contain such organisms is simply an opinion. It is not supported by observations that lead us to accept it as a fact. The more conservative of those who believe in a causal relation between the air of sewers and pathological conditions are coming to the opinion that it is not directly concerned in the production of disease, but that its continuous respiration in some way interferes with the normal vital resistance of the tissues, and thus renders them more susceptible to infections to which they may be exposed.

The author detailed his experiments on animals, and concluded that if experiments upon animals are of any value in demonstrating the positive or negative effect of air saturated with the gaseous products of decomposition, it does not seem reasonable to suppose that the air of a sewer or cesspool, in the enormous dilution in which it exists at the time that it reaches an individual in a house to which it has access, can be of much importance either in the direct production of the diseased conditions or in influencing the vital powers of the resistance of the individual who inhales it.

THE EFFECT OF SEWER GAS IN THE PRODUCTION OF DISEASE,

by DR. A. JACOBI, of New York.

The author presented the following conclusions:

The atmosphere contains specific germs both living and dead. They are frequently found in places which were infected with specific disease.

In sewers, fewer such germs have been found than in the air of houses and school-rooms.

Moist surfaces, such as the contents of sewers and cesspools and the walls of sewers, while emitting odors, do not give off specific germs even in a moderate current of air.

Splashing of the sewer contents may separate some germs, and then the air of sewers may become temporarily infected, but the germs will sink to the ground gain.

Choking of the sewer, the introduction of hot factory refuse, leaky house drains and the absence of traps may be causes of sewer air ascending or being forced back into houses, but this complication of circumstances certainly will be rare.

Whatever arises from the sewer under these circumstances is offensive and irritating. A number of ailments, such perhaps as sore throat, may originate from this cause, but no specific disease will be generated by it except under the rarest of conditions; for specific germs are destroyed by the process of putrefaction in the sewers, and the worse the odor the less is the danger, particularly from diphtheria. The causes of the latter disease are very numerous and the search for the origin in an individual case is often unsuccessful. Irritation of the throat and naso-pharynx is a frequent source of local catarrh. This creates a resting-place for the diphtheria germs, which are ubiquitous during an epidemic, and thus an opportunity for diphtheria is furnished.

Of the specific germs, those of typhoid and dysentery appear to be the least subject to destruction by cesspools and sewers. These diseases appear to be sometimes referable to direct exhalations from privies and cesspools. Fewer cases, if any, are attributable to sewer air.

A simple outlet from the sewer would be dangerous to the general health because of the density of the odors (not germs) arising therefrom. Therefore a very thorough and multiple ventilation is required.

The impossibility or great improbability of specific diseases arising from sewers into our houses protected by good drains and efficient traps must, however, not lull our citizens and authorities into indolence or carelessness; for the general health is suffering from the chemical exhalations, and the vitality of cell-life and the power of resistance are undermined.

SEWER GAS A CAUSE OF THROAT DISEASE, OR THE EFFECT OF BAD DRAINAGE ON THE THROAT.

by DR. BEVERLY ROBINSON, of New York.

Defective sewage may produce a sore throat of a benign character, which affords a soil suitable for inoculation by the diphtheria germ when present in the air. It is an admitted fact that the throat swarms with bacteria at all times; and possibly the Löffler bacillus is among these occasionally, but they are incapable of doing much harm if the individual is in good health. Through the depressing influence brought about by bad drainage, etc., they are capable of multiplying and increasing in virulence, and finally causing infectious sore throats. It is therefore clear how important it is to keep up an excellent condition of general health to avoid contracting throat disease. Proper disinfecting washes and gargles are also of value. While the connection between effluvia from sewers and drains and the condition of the throat cannot always be determined, yet in many cases it is clearly demonstrated. That many cases of tonsillitis are immediately caused by the air of sewers and faecal emanations scarcely admits of doubt. In some cases the sore throats have been confined to particular parts of houses; and when the bad sewage has been remedied, they have ceased to recur. When cases of diphtheria, tonsillitis or erythematous sore throat occur in houses where the plumbing is found to be defective, we should be careful not to ascribe these diseases necessarily to this cause. While throat affections often occur where the

drainage is bad, they may occur where the sewage is in perfect condition or where there is no sewage at all.

The second part of the Session was under the direction of the American Dermatological Association. The subject for discussion was

LEPROSY.

JAMES NEVINS HYDE, M.D., of Chicago, read the opening paper, which was on

THE DISTRIBUTION OF LEPROSY IN NORTH AMERICA.

Reference was first made to the different ways in which the disease could gain entrance into the United States. The northern part of the country has suffered far less than the southern, and even in the latter portion the disease is more common in the southern than in the northern provinces. The United States is exposed to the entrance of leprosy from the four principal points of the meridian, north, south, east and west. That the total result up to the present time is insignificant, has been due, not to wisely-directed vigilance, but rather to the general excellence of the habits of the people, and to their resources and environments.

At the present time the distribution of leprosy in the United States cannot be determined with any accuracy. The credit of being the first to collect statistics as to the number and location of lepers is due to the American Dermatological Association. According to these statistics and those of others, it may be said that the cases of leprosy in the United States have been distributed as follows: Arkansas 3, California 158, Dakota 2, Florida 6, Georgia 1, Idaho 2, Illinois 13, Indiana 2, Iowa 20, Louisiana 83, Maryland 4, Massachusetts 5, Minnesota 120, Missouri 2, Mississippi 2, New York 100, New Jersey 1, Oregon 3, Pennsylvania 6, Utah 3, Wisconsin 20, making a total of 560. The accumulation of cases is found to be principally at points of commercial activity. The number of lepers in this country at the present time cannot be definitely stated.

These facts call for intelligent discussion and for wise provision looking after the needs of the unfortunate leper, and for the safety of the community in which the infected are now living. Tuberculosis alone, at the present time, exposes the health of our population to a greater danger than leprosy. The presence of leprosy in this country offers a constant menace to its inhabitants, and proposes a problem in State and sanitary science which I believe the general government alone can readily solve.

THE CONTAGIOUSNESS, PROPHYLAXIS AND CONTROL OF LEPROSY,

by DR. JAMES C. WHITE, of Boston.

The establishment of the proof of the contagiousness of a disease should be based upon the following points:

- (1) The history of its action upon communities or nations.
- (2) The study of its action upon individuals.
- (3) Its resemblance to other affections generally regarded as contagious.
- (4) The establishment of a satisfactory cause for such contagion.
- (5) The influence of control upon its history and course.

These tests were then applied to the disease under consideration:

(1) The history of its action upon communities and nations. Reference was made to its course in mediæval Europe, where, introduced from the East, it became a pestilence of such overwhelming proportions that no influences of heredity alone could account for its spread. Belief in its contagious nature was then universal. In our own day, the extraordinary rapidity of the spread of the disease in the Hawaiian Islands can be accounted for on no other grounds than its infectious nature. The same is true of its introduction and spread in British Guinea, Trinidad and other places.

(2) The study of its action upon individuals. Great difficulty is here met with on account of the long period of incubation of leprosy, which may be of two, five or even ten years' duration. Such a retardation of the tangible effects of the contagion renders direct historical proof in individual cases almost an impossibility. Again, the tissues of animals other than man thus far studied show themselves indifferent to inoculation experiments. The possibility of using human tissues for such demonstration in satisfactory sufficiency is too remote for serious consideration. In one case a condemned criminal was inoculated, and three years later leprosy appeared. Reliance must therefore be laid upon a careful study of the beginning of endemics in small communities. Another class of evidence is the acquisition of the disease by immigrants of non-leprous nationality into leprous countries. Of this there are many instances on record. Another important fact is the development of leprosy among the personal attendants of lepers. Of this several instances were cited.

(3) Resemblance to other affections generally regarded as contagious. Under this head, reference was made to the many points of resemblance between leprosy and syphilis and tuberculosis, and the speaker held that these strong resemblances suggested an intimate relationship in etiology and pathology.

(4) Establishment of a satisfactory explanation of its contagiousness. With the discovery of the bacillus lepræ, the cause of its contagious nature was demonstrated as clearly as was that of tuberculosis by the discovery of the bacillus tuberculosis. Leprosy is preeminently a bacillus disease, for this organism is found in rich abundance in the tissues.

(5) Influence of control upon its history and course. In mediæval Europe, when the disease was regarded as infectious, the leper was segregated and placed in lazaretos. In later centuries, when the disease had been thus controlled and confined to a few districts, the belief grew up that the disease was not contagious, but was hereditary, and scarcely any one thought of questioning this dictum. At the International Medical Congress in 1876, the author had called attention to the prevalence of the disease in the United States. In 1882 he again called attention to the subject in a paper presented to the American Dermatological Association. His conclusions that the disease was increasing to an alarming extent, and that it was contagious, at that time found few supporters, but since then professional opinion has greatly changed. A study of the disease in other countries shows that where laws for its control have been enacted there has been a great decrease in the number of cases, and that where it has been given free license the number of cases has rapidly increased.

While not denying the possibility of the transmis-

sion of leprosy by heredity, the author held that its apparent occurrence in any instance should not be accepted without the absolute demonstration of the impossibility of inoculation after birth. He believed the theory of heredity to be a dangerous one, and that the sterner judgment of the Middle Ages, which made the leper individually the responsible agent rather than the progenitor, must again be adopted before the affection can be exterminated.

With regard to the prevention and control of leprosy in the United States, the consideration of the following propositions was recommended:

(1) Every physician should be compelled by State law to report to the nearest board of health the existence of a case of the disease, and the neglect to do so on the part of the medical attendant or a member of the leper's family should be a penal offence.

(2) Immigrants affected with the disease should be arrested at ports of entry and along our border, and turned back to their previous homes by the authority of the National Board of Health.

(3) Graded hospitals should be established by the national government, in insular localities where possible, within which both suspected and confirmed cases should be confined, and to which all access should be prevented excepting under proper restrictions.

Such compulsory isolation may be considered cruel to the few, but its longer neglect on our part is certainly a greater cruelty to the many, for in no other way shall we exterminate this most miserable disease.

In the general discussion of the subject, DR. GEORGE H. FOX, of New York, said, that whatever might be the result of inoculation experiments, he was sure that those who had given special attention to the study of leprosy would agree that the disease was communicable, but that the danger of infection from association with the leper is extremely slight. In the United States, the disease has never shown any tendency to spread among those brought in contact with communities of lepers. He thought that there was no necessity for the segregation of the lepers to be found in the United States. To forcibly take these individuals from their homes would be an injustice which the slight menace to the general health would not warrant. Syphilis and tuberculosis are much more liable to be communicated to others than is leprosy. He believed that many cases of leprosy are amenable to treatment and capable of being cured, and he would be in favor of the establishment of hospitals for leprosy where these cases could be studied.

DR. JOSEPH B. BRYANT, of New York, advocated the institution of active measures, because such a course would be a humane one as far as the leper was concerned; it would conduce to public security and confidence; and it would secure good sanitation and better therapy. He offered the following propositions:

(1) That a wise public policy and humane considerations demand that lepers be not permitted to associate with the unaffected.

(2) That the exercise of local authority for their segregation is unwise and unsanitary, as establishing innumerable abiding-places for the disease at great expense, and without the assurance of proper surveillance.

(3) That a safe, prudent and humane policy demands that lepers be properly segregated under the care and control of the general government.

DR. WALTER G. WYMAN, Surgeon-General, United States Marine-Hospital Service, described the effect of the quarantine laws which had been promulgated with the object of preventing the entrance of lepers into the United States. He then considered the reasons in favor of and against the national control of leprosy, and presented the draft of a bill relating to this object. He also suggested that, as a preliminary measure, a leprosy commission should be appointed to study the disease and report upon the best methods of controlling the disease in this country. For himself, he believed that leprosy should be under national control.

DR. ARTHUR VAN HARLINGEN, of Philadelphia, dwelt upon the importance of all physicians studying leprosy so as to be able to recognize its earlier manifestations, which were frequently overlooked. He had good reason for saying that, notwithstanding the rigid quarantine laws, many cases of leprosy had gained access to the country, although they had been subjected to some sort of an examination. This was due to a failure to recognize the early manifestations of the disease.

THE DIAGNOSTIC FEATURES AND TREATMENT OF LEPROSY,

was the subject of a paper by DR. P. A. MORROW, of New York, which was read by title.

THURSDAY AFTERNOON, MAY 31st.

The first portion of the session was under the direction of the American Association of Genito-Urinary Surgeons.

DR. EDWARD L. KEYES, of New York, read the first paper which was on

NEPHRITIS IN ITS SURGICAL ASPECTS.

In opening the discussion on this subject, Dr. Keyes announced his intention of confining himself to a consideration of that form of surgical nephritis in which suppuration occurs, either spontaneously in the course of suppurative disease of the urinary tract below (ascending pyelo-nephritis), or originating below as a result of infection by the surgeon, or in the blood (the descending variety) — all the various forms of so-called surgical kidney.

He divided his paper into three parts: (1) introductory, (2) practical, (3) bacteriological. The introductory section demonstrated by a plentiful citation of authority, mainly French and German, the following points:

(1) Without microbic infection, suppuration in the kidney is impossible.

(2) The bacilli found most often are, notably, the bacterium coli communis, less often (alone or in company with the bacterium coli) the staphylococcus pyogenes aureus and the streptococcus pyogenes.

(3) These bacilli find entrance in a variety of alleged ways.

(4) The introduction alone of these bacilli does not occasion ascending pyelitis, or even necessarily cystitis. It is as much a question of soil as it is of seed.

(5) The soil is made receptive for microbic invasion by a variety of local physical maladies — by anything that interferes with free, urinary outflow; by over-distention or tension; and also by traumatism, and failure of the general vitality of the individual. The kidney is especially prepared for invasion by dilatation of the ureters, a dilatation always occurring from above

downwards, always due to a moderate obstruction of urinary outflow below, never to sudden stoppage of the urinary drainage nor to back-pressure of the urine.

The practical part of the paper contained Dr. Keyes's personal views upon urinary asepis and antiseptis, and detailed the methods which he employed in everyday clinical work and the solutions he used, together with his method of instituting catheter life upon an old subject with clear urine atony, retention, thin-walled bladder, dilated ureter and damaged kidney (as regards its vitality).

The bacteriological study was conducted by Professor Dunham of Bellevue Hospital Medical College, under Dr. Keyes's direction, to determine the destructive or inhibitive power over the three bacilli under consideration, of a great variety of medical substances often used for local antiseptic purposes in the treatment of vesical suppuration, and of a variety of urines medicated by the ingestion of a number of different drugs. About five thousand tubes were examined and the conclusions generalized and tabulated, with the result of showing theoretically which drugs possessed the greatest value under varying conditions—those of direct infection by the surgeon, the tissues not being involved; and those in which, chronic suppuration already existing, the bacilli were protected from the action of the antiseptic. These conditions were reproduced in the laboratory, a method of investigation apparently novel and yielding suggestive results. The experiments consisted in comparing the action of the same drug upon bacteria in Group I, where direct infection immediately created was simulated, with its effect on bacteria in Group II, where chronic inflammation was simulated, the bacteria being more or less protected.

This investigation showed that nitrate of silver was by far the most reliable agent we possess in counteracting the effects of local contamination, while corrosive sublimate was more reliable in Group II, where the tissues were involved. Salicylic acid was shown to be a very reliable antiseptic, and Dr. Keyes proposes a new solution for greater convenience of use. Boracic acid has little or no value, common salt being about as good. Many other agents were experimented with. The various medicated urines showed little or no inhibitive power over bacterial growth.

The following general conclusions were presented:

- (1) Healthy urine is sterile.
- (2) Purulent urine is always microbic.
- (3) Microbic infection takes place from within the body by a number of methods in the course of disease; it is often brought about by instrumental manoeuvres on the part of the surgeon.
- (4) A healthy organism and vigorous bladder can cope successfully with microbic invasion, and rid itself spontaneously or with a little aid of all damage arising therefrom, showing little or even no inflammatory response.
- (5) A suitable condition of the patient's soil is essential to the propagation and perpetuation of the inflammatory phenomena upon the urinary tract, after microbic invasion.
- (6) This condition, intensified by traumatism and physical weakness, notably of the degenerative variety, is most intense when there is vesical distention with atony, and when the ureters are dilated and the kidneys involved in the changes incident to tension below, namely, atrophy and sclerosis above, with or without surface catarrh.

(7) Under these circumstances surgical pyelonephritis is most likely to declare itself as a result of microbic infection from below (occasionally from above) in the course of suppurative disease.

(8) Asepsis, antiseptis and sterilization of urine are ends to be aimed at in genito-urinary surgery, but like all other greatest goods not yet attained in perfection. Much, however, can be done by local means in a prophylactic and curative way, little by internal medication, and possibly as much or more than by any other means by flushing the urinary passages with natural mineral waters.

DR. GEO. M. STERNBERG followed, with a paper on

THE BACTERIOLOGY OF NEPHRITIS.

Ascending nephritis or pyelonephritis is very commonly secondary to cystitis of long standing.

Recent researches show that the bacillus coli communis is found more frequently than any other micro-organism in the so-called "surgical kidney." This bacillus is now known to be the usual cause of peritonitis. It has been obtained in pure cultures in some cases of abscess of the liver, from urinary abscess and from the pleural cavity in certain cases of pleurisy.

Injections of a pure culture made into the ureter, after tying it below the point of injection, have been shown by Schmidt and Aschoff to give rise to pyelonephritis, and the changes induced are said to correspond with those seen in the "surgical kidney" of man. Clado in 1887, Albarran and Halle in 1888, and Rovsing in 1890, have described non-liquefying bacilli found by them in the urine of cases of chronic cystitis and of pyelonephritis, which appear to be identical with the bacillus coli communis, which has been shown by the subsequent researches of Schmidt and Aschoff and of others, to be very variable in its growth on various culture media—upon gelatine the growth is sometimes transparent and sometimes opaque.

Krugius in 1891, first identified the bacillus described by Clado (his "bacterie septique") and by Albarran and Halle ("bacille pyogene") with the bacillus coli communis, and this identification is verified by the researches of Achard and Renault, Schmidt and Aschoff, and others. In 22 cases of cystitis studied by him (1892) Krugius obtained the bacillus coli communis 14 times in pure cultures. Reblaub (1892) obtained the same bacillus in pure culture in 6 cases out of 16 cases of cystitis examined.

The number of cases of pyelonephritis reported by various authors since 1889, in which the bacillus coli communis was found, and was probably the cause of the ascending nephritis, is 29, and in 20 of these it was found in pure culture.

The etiological relation of this bacillus to ascending nephritis seems extremely probable in view of the facts referred to. Certain cases appear to be due also to the presence of one or more species of proteus, and possibly to other micro-organisms.

The general discussion was participated in by Dr. George Chismore, of San Francisco, Cal., and Dr. Francis S. Watson, of Boston.

The second portion of the session was under the charge of the American Gynecological Association.

The first paper by DR. WM. M. POLK, of New York, was entitled

THE CONSERVATIVE SURGERY OF THE FEMALE PELVIC ORGANS.

The data from which the author drew his deductions have been furnished by a study of 164 cases on which he had done abdominal section for disease of the appendages. Of these, 64 were operated on by the radical method, and 100 by so-called conservative measures. By the term conservative he meant to indicate the retention of all tissues which have a reasonable chance of adding to the local or general well-being of the individual. Conservative surgery is applicable to traumatism, non-malignant disorders and the early stages of infectious disorders of the female pelvic organs.

The advisability of conservative operations on the perineum, vagina and cervix has long been recognized and accepted. The author then went on to speak of myomectomy. Where the tumor has a pedicle or a distinct capsule and the tumors are not too numerous, operations for the removal of the tumors themselves may be indicated. Ligation of the broad ligament has been suggested in order to check the growth and lessen the hemorrhage. This operation seems to be capable of filling a valuable place for these indications. It seems to be better than the operation of oöphorectomy, but as yet our knowledge is insufficient to enable a more definite statement to be made.

One of the most conservative operations is curetting, with the drainage and depletion to be obtained by packing. This is applicable in all forms of endometritis and metritis, whether acute or chronic. In acute or subacute inflammation after abortion or labor, it is of great service if done at once.

It may be that in affections of the appendages, efficient depletion can be secured by the cavity of the uterus, and will do much toward effecting a cure. The results should be best in the early stages of salpingitis and oöphoritis, but the chronic cases are not beyond its influence. If done properly, it is harmless and renders the secondary operation safer. The more the speaker had employed this method of treatment, the better was he pleased with it. Women are the better mentally and physically for the maintenance of menstruation and ovulation. Until recently many conditions of the tube or ovary were considered adequate causes for their removal. Such is not now the case. The functions of menstruation and ovulation should be preserved when it can be done without sacrificing the patient's health or life. In cases of destructive inflammation of the appendages, the operation is best done after the subsidence of the acute inflammation. The tendency of these inflammations is in the direction of resolution. There are many cases of occluded adherent tube in which the ovary is in good condition. The same statement applies to some cases of pyosalpinx and many cases of hæmatosalpinx. The author's proposition was to remove such tubes and leave such ovaries. The nearer the patient is to nature's menopause the less is the necessity for such conservatism. In early life it is urgently necessary. He had operated on 45 cases in this way; and in their ability to work and enjoy life they are in as good condition as any equal number of cases of oöphorectomy. Mentally they are far better.

In 36 cases he had resected ovaries the seat of simple or blood cysts. In all but five cases the results were entirely satisfactory. In two cases there was fresh development; and in three suppuration in the cyst occurred due to infection from the catgut. Where the tubes have been simply adherent, they are released and allowed to remain. Twelve such cases have done

well with the exception of one where gonorrhoeal infection spoiled the work. Where the abdominal opening is closed, this is opened and the fimbriated ring stitched back.

As demonstrating the possibility of pregnancy after operations of this character, he reported five cases from his own practice where women had become pregnant after such procedures. The precise question is, however, not so much the possibility of pregnancy but the mental, moral and physical influences of allowing the ovary or a portion of it to remain.

DR. WILLIAM GOODELL, of Philadelphia, said that he had taken the liberty of changing the title of his remarks to

THE CONSERVATIVE TREATMENT OF THE FEMALE PELVIC ORGANS,

preferring to use the word "treatment" instead of "surgery." This enlarged the scope of the subject, and was more in keeping with his views; for he held that besides strictly surgical ones, there were other kinds of conservative treatment which are especially adapted to the ailing female organs. He considered the whole question of the proper treatment of these disorders to hinge on the effect of castration in women. These effects are prolonged and distressing vaso-motor disturbances (often very hard to bear) and a tendency to morbid brooding, low spirits, melancholy, suicidal impulses, and even to insanity. Then, again, castrated women are liable to become unsexed to that extent as to lose all sexual feeling, or to have it greatly blunted. In some cases senile atrophy of the genitalia takes place, or in its place a hypertrophic condition of the vulva occurs, which forbids coition and causes much domestic unhappiness. An inevitable and deplorable result is sterility, which is often a cause of great sorrow. The author laid stress upon the prevalent lay opinion that women deprived of their ovaries are thereby wholly unsexed. Castration in the male or in the female is alike regarded as a sexual mutilation to which is attached a stigma. No woman would marry a eunuch, and few men would wed a woman without ovaries. It is then manifest that during the period of woman's menstrual life her mental, physical and social welfare depends largely upon the continuance of the catamenial and reproductive functions. Hence the conservation of those organs which preside over these functions is of the utmost importance.

The speaker reprehended that hasty operative interference based on the plea that chronically diseased appendages are dangerous to life, for in his experience few women perish from chronic disorder of these organs even when pus is present. More women die from the radical operation than from the disease itself. To restore such women to health, abdominal section is by no means always necessary. Many have been cured by curetting and draining the womb. Others he had seen get well under the use of rest, massage, electricity, alteratives and local applications, although they had been sent to his private hospital to have their appendages removed. In a few instances among his own patients this treatment was followed by conception and pregnancy.

The possibility of a closed-up Fallopian tube regaining its lumen is warmly disputed; but since uterine fibroids of large size spontaneously disappear through retrogressive metamorphosis, why may not the thin

tubal septa of inflammatory origin also melt away and restore the bore of the tube? He cited examples in which great disorganization of the tubes and ovaries did not prevent conception. Cases were also related in which, after a small fragment of an ovary and a short stump of a tube were left behind, pregnancy took place.

In view of these interesting facts, he advised that when therapeutic measures failed and the final appeal was made to the knife, as little as possible of the appendages should be taken away. If the tubes and ovaries are simply adherent and not otherwise damaged, they should merely be freed from these adhesions, and not extirpated; if they are diseased, only the unhealthy portions should be removed. He had found that a piece of ovary not larger than a small bean was quite ample to maintain intact menstruation and the sexual feelings.

He contended that the aim of modern surgery is conservation. Limbs, members and organs are now saved which formerly would have been sacrificed. This is its glory, and this has been brought about by antiseptics. On the other hand, antiseptics, by the glamor of success, so dazzled modern gynecology as to make it a spoiler rather than a conservator. Reform here is greatly needed, the reform of conservative gynecology.

The general discussion was participated in by Dr. Lutaud of Paris, Dr. Matthew D. Mann of Buffalo, Dr. Joseph Taber Johnson of Washington, Dr. Howard Kelly of Baltimore and Dr. Florian Krugg of New York.

Recent Literature.

Treatise on Ruptures. By JONATHAN F. C. H. MACREADY, F.R.C.S., Surgeon to the Great Northern Central Hospital; to the City of London Hospital for Diseases of the Chest, Victoria Park; to the Cheyne Hospital for Sick and Incurable Children; to the City of London Truss Society; and Surgeon in London to the Merchant Taylors' Company's Convalescent Homes at Bognor. Philadelphia: P. Blakiston, Son & Co. 1893.

The author divides this book into two parts. Part first is on ruptures when the function of the bowel is undisturbed. Part second is on ruptures where the function of the bowel is interrupted.

As surgeon to the City of London Truss Society, Mr. Macready has had an exceptional opportunity to study herniæ, particularly from the non-operative point of view. Statistics are presented in this work in a thoroughly judicial way; they are so misleading at times that it is a pleasure to read the unbiased presentation of this interesting subject by Mr. Macready.

The forms of herniæ are clearly described, and attention is called to the changes which occur in the shape of the abdomen, especially in long-standing cases of hernia.

The trusses which are shown in the illustrations are not models of lightness; they suggest clumsiness.

The subject of hernia is presented in a clear and scholarly manner. The list of references at the end of each chapter is especially to be commended. The book's value is added to by an admirable index. It is well illustrated, printed and bound.

THE BOSTON Medical and Surgical Journal.

THURSDAY, JUNE 7, 1894.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THIRD TRIENNIAL CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

THE Third Triennial Congress in Washington of the fourteen special national associations and societies has furnished additional proof, if any were needed, of the distinct and increasing value of such an organization to medical science and medical practice and to the higher aspirations of the medical profession in our country. It is a comparatively short time—only thirty years—since the first of these associations began to be started amid some misgiving and against some opposition. The older associations soon proved their usefulness to the profession, and successive years have witnessed the formation of others in new fields until the present number has been reached, and all departments of medicine are represented from anatomy and physiology, through general medicine and general surgery to climatology, pediatrics and genito-urinary surgery. All of these associations are flourishing; their annual meetings are well attended; good work is presented and intelligently discussed; and membership is prized and sought for by the best men—teachers and practitioners—in the profession.

It would seem, however, as if the division of subjects had gone quite far enough, and we see no good reason for the further multiplication of separate societies. But there is every reason for the continuance and perfection of these triennial gatherings of all the separate societies at one time and one place. The very subdivision and specialization of professional interest and work is the strongest argument in their favor. The opportunity afforded for the discussion of such subjects as those appointed for consideration in the General Sessions of this Congress, by representative members of the special societies from their different points of view, is of great value if availed of, and might be of much greater value if made more available.

Whilst appreciating the force of the reasons which led to the adoption of the arrangement of this year, we still think it a mistake to attempt the presentation and discussion of two important and debatable subjects in

one afternoon, allotting to each only an hour and a half. The result must inevitably be that which obtained this year. We shall have a presentation of the subjects, an excellent one it is true, but still such as might be had at an annual meeting of the special society of the day; but the discussion, and such a discussion as is only possible under the conditions of the triennial congress, is conspicuous by its absence. It would be better to have one subject treated as it might and should be treated by such a body of men, than to give each association more frequently the empty honor of selecting and presenting the topic of the day. We hope the Executive Committee will see its way to putting the Congress in a position to do for the profession in this respect what may reasonably be expected of it.

The best papers presented, as a rule, were the short ones, and the presiding officers would do well to be more rigorous with those readers who have not learned to appreciate the merit and the possibilities of condensation.

Under any management, the great advantage of meeting distinguished and rising collaborators in congenial pursuits is inherent in such a reunion. Men from different parts of the country make new professional acquaintances and cement old friendships. Junketing is happily absent, the only general festivities being the gracious reception by the President and Mrs. Cleveland of the members of the Congress, and a subscription dinner at the Arlington Hotel.

The weather was all that could be desired, and Washington looked its best; under such conditions it is a national capital of which no American need be ashamed, especially if he avoids the so-called debates in the Senate and House of Representatives. No wonder the "industrialists" (we refer to Coxey armies, not to the "trusts" or "industrialists" of the Stock Exchange) were tempted to look upon it as a place of hope and promise!

The *Congressists* registering numbered four hundred and ten, and of these comparatively few had cause to regret their visit. The sufferings experienced three years ago were not repeated, and, with few exceptions, the gastro-intestinal tract made no protest. Notwithstanding this amelioration, the Executive Committee was empowered to name the place of meeting of the next Congress, Washington not being specifically designated.

At the business meeting held Friday afternoon, June 1st, at the instance of the Dermatological Association, it was voted to memorialize the Congress of the United States with the view to the appointment of a commission of five to investigate the prevalence of leprosy in the United States and in the countries upon its borders and to suggest means for its control.

A resolution was passed entering the most earnest protest of the Congress against any legislation tending to interfere with the advancement of medicine by means of experimentation upon animals conducted by properly qualified persons.

A resolution was passed that, in the opinion of the Congress, the proposed reductions in the number of medical officers in the army and in the appropriation for the Library of the Surgeon-General's office, are unwise and are contrary to the best interests, not only of the army, but of the medical profession of this country and of all who depend upon its members for skilled professional services.

THE CONVEYANCE OF SCARLET FEVER AND DIPHThERIA BY PUBLIC CARRIAGES.

It has not infrequently been noted that a ready source of infection with scarlet fever and diphtheria exists in the public hackney vehicles of a large city—inasmuch as they are used without regard to contagion by patients with such diseases. Even among physicians it is not, however, generally known that such a source for contagion has no legal right to exist, and that with a little energetic coöperation it might practically be done away with.

The great majority of all cases of these contagious diseases carried in public vehicles in Boston are patients taken to its City Hospital. A large number of these patients are sent to the hospital by their physician, who is probably in most cases ignorant of the police regulation forbidding such procedure, which reads: "No person having charge of any hackney carriage shall receive or permit to be placed therein, nor convey in or upon the same, any person sick or infected with any contagious disease, or the body of any person deceased from such disease."

The drivers of herdies and cabs are, of course, aware of this regulation, but are too often willing to take their chance of escaping conviction and fine. Convictions have not been many, fines have not been large and have involved no loss of license, so that financially the risk is a good one. The sense of moral responsibility toward the public is not highly developed in the average cabman, nor is his diagnostic knowledge of disease acute. Heavier penalties would doubtless improve both faculties.

It is by the physician, however, that much may be done towards abolishing this dangerous practice. In the past many have sent their contagious patients to the hospital in cabs through ignorance of this rule or through thoughtlessness.

The City Hospital sends its ambulance, free of charge, for any and every case of scarlet fever or diphtheria which it can admit. The transfer from the house to the hospital can be made with as much speed and more comfort in an ambulance than in a cab, and without subsequent exposure of other people. Now that attention has been called to this easily remediable evil, it is hoped that all physicians will coöperate in suppressing it by refusing to sanction carriage-transfer of patients, and insisting that cases which they send to the hospital be taken only in the proper ambulance.

If physicians are to be firm in requiring their patients to make use of a hospital ambulance they have

right to expect that, on their side, the hospitals will take all precautions to have no secondary infection traceable to the use of the same ambulance for conveying both scarlet fever and diphtheria patients. There are many cases in which, either from an undetermined diagnosis or from personal feelings of the patient or the family, the physician's line of duty to his patient and to the general public is not an easy or simple one to follow. In such cases his position of insisting on the use of a hospital ambulance will be made much easier and more secure if he can assure his patient that the ambulance is not used indiscriminately for both scarlet fever and diphtheria. In this city he cannot make this statement, as there is but one ambulance for contagious diseases at the City Hospital. He should, at least, be able to state that the same blankets, pillows and mattress are never used without precautions for more than one patient, and that the ambulance is thoroughly disinfected after every trip.

RECENT SANITARY IMPROVEMENTS IN HAMBURG.

THE great Hamburg fire, half a century ago, prepared the way for the broad streets, the great water park made by damming the Elbe and flowing extensive flats, the excellent water-supply and the admirable system of sewers which made the city the pioneer, under the distinguished English engineer Lindley, in modern sanitation. Paris, and next London, but in a far inferior way, followed with their improved sewerage, and then came the filtration system of the London water-supply. The exemption from cholera in Hamburg in subsequent epidemics, furnished the most powerful argument in Europe, and especially in Germany, for cleaning up their cities and for establishing the theory that cholera comes chiefly from drinking water contaminated by human excrement.

It is rather curious that, in the growth of the city and in the subsequent contamination by human excrement of the river providing their drinking water, Hamburg should have suffered so from cholera in 1892, as to be the great lesson to the few remaining doubting Thomases who held to Pettenkofer's ground-water theory of the origin of that disease.

Under the title of "Hamburg's New Sanitary Impulse," in the June number of the *Atlantic Monthly Magazine*, Mr. Albert Shaw has admirably described the methods of sewage-discharge, of a new intake from the river and of a vast system of water-filtration which had been planned before the last epidemic.

Under an American, Dr. Dunbar, the hygienic laboratory makes frequent and minute bacteriological examinations of the drinking water, and carefully notes the results of filtration. It would be curious to know whether the very valuable original work in that direction done in recent years by the Massachusetts State Board of Health had given any hint or had furnished any knowledge as to the efficacy of efficient filtration in making safe water which had contained

the specific germs of disease. The fact had been demonstrated practically by the London and Altona filter-beds, but the scientific investigations made have provided the explanation of the fact and showed the degree to which filter-beds could be depended upon.

MEDICAL NOTES.

AN HONOR TO DR. GOODELL. — Dr. William Goodell, of Philadelphia, has received the honorary degree of LL.D. from Jefferson Medical College.

BILLROTH'S SUCCESSOR AT VIENNA. — Professor Dr. Czerny, of Heidelberg, is reported to have been officially called to be Billroth's successor at the University of Vienna.

CHOLERA IN PRUSSIA. — Cases of cholera were reported lately from Upper Silesia and the city of Stettin. Dr. Fairfax Irwin, of the Marine-Hospital Service, Sanitary Inspector at Berlin, was immediately ordered to Stettin to make an investigation.

A SURGICAL OPERATION UPON KAISER WILHELM II. — It has been officially reported from Berlin that a small encysted tumor was removed from the Emperor's cheek last week by Drs. Bergmann, Leuthold and Schlange. It is stated that the operation was done without anæsthetics.

SMALL-POX IN CHICAGO. — The Health Department of Chicago is having great difficulty in preventing the spread of small-pox, owing to the opposition of the Polish and Bohemian population, among whom it is chiefly epidemic. In the house-to-house investigation which they have been forced to make, the Board is obliged often to have police protection, and in many cases to break down the doors of houses with sledge-hammers. On June 1st fourteen cases were found in this manner, concealed in tenement-houses.

A DISSATISFIED PATIENT. — The cable announces that Prince Bismarck's left leg is so feeble he can only stand on it a few minutes at a time. He explained to a friend that upon the recommendation of a Russian Grand Duchess he consulted a Russian doctor some time ago. He has since learned that this doctor was an idle and ignorant fellow — the head of a children's hospital in St. Petersburg, where he killed off 3,000 patients annually! "He ruined my leg, and I have suffered the consequences ever since."

INDIVIDUAL COMMUNION-CUPS. — The opposition to the common use of one communion-cup is increasing rapidly among the laity, as well as among physicians, for the laity nowadays are by no means ignorant of bacteriology. The fruit of the tree of knowledge is bitter indeed, and is now found to be infected with bacilli. Kissing, the world old expression of bodily love, has been found scientifically dangerous and is going out of use, so it is said; and now even a spiritual love must not manifest itself by the use of a common cup. As one advocate of bacterial individuality has recently written, "Let us mingle our tears in sym-

pathy, our prayers in supplication, our songs in praise, but permit each one to possess in solitude his individual bacteria."

A NEW ENGLISH "SPECIALIST." — According to the *British Medical Journal*, a new specialist has made his appearance in England, and at present is busily engaged in sending his circulars to his expected patrons. As this new operator is a "circumcision specialist," his notices are sent to newly-made fathers of finely-formed but too preputially endowed sons. The following are extracts from one of these circulars: "Every Circumcised person have always been so hardy and thereby escaping obscure nervous disorders, the facts of which are acknowledged by highest medical authorities." "Every invalid or victim of some obscure nervous disorder should not neglect this, as it will materially assist in restoring him to health." "What are the benefits derived therefrom? Predisposition to and Exemption and Immunity from disease."

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — During the week ending at noon June 1, 1894, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 37, scarlet fever 55, measles 25, typhoid fever 1.

A CASE OF SMALL-POX IN RUTLAND, VT. — Last week a traveller from Chicago was taken ill at a hotel in Rutland, Vt., with what proved to be small-pox. The hotel was at once quarantined by the health authorities.

AWARD OF THE BOYLSTON MEDICAL PRIZE. — The Boylston Medical Prize for 1894 has been awarded to Dr. Norman Walker, of Edinburgh, Scotland, for an essay entitled "The Histological Varieties of Cutaneous Cancer."

DR. WALCOTT'S SMOKE-TALK AT THE UNIVERSITY CLUB. — Dr. Henry P. Walcott, Chairman of the State Board of Health, gave a smoke-talk at the University Club last Wednesday upon the proposed changes in the Charles River Basin.

THE MASSACHUSETTS CREMATION SOCIETY'S INVITATION TO PHYSICIANS. — In connection with the annual meeting of the Massachusetts Medical Society, the building of the Massachusetts Cremation Society at Forest Hills will be open for inspection from two to four P. M. on Tuesday, June 12th, when the heat will be applied to the retorts and the process carefully explained.

NEW YORK.

SMALL-POX QUARANTINE AT SING SING REMOVED. — On June 2d, Warden Durston removed the quarantine from Sing Sing prison, which had been closed to visitors for nearly two months on account of several of the convicts having had small-pox. All of the patients have now recovered and are at work again.

THE DEAD FISH IN THE WATER-SUPPLY. — Considerable alarm was occasioned a short time since by

the publication in the newspapers of the report of Dr. J. G. Wood, health-officer at Brewster's, in the Croton water-shed, that there were large numbers of dead fish in Haines' Pond, a part of the Croton system, near Sodom Reservoir, and that he was led to believe that some epidemic was prevailing among the fish which might pollute the water. The gills of the dead fish, he claimed, had a diphtheritic appearance. The matter was at once investigated, although the officials of the New York Board of Health, recognizing the fact that diphtheria is a disease confined exclusively to warm-blooded animals, felt that the only danger that could arise from the presence of dead fish in the water was from decomposition, and that that was very slight. It is stated by Dr. Biggs, bacteriologist to the Board, that chubs, or suckers, are susceptible to a peculiar disease every spring, which develops a fungus-like growth about the head, and which carries them off in great numbers. At the meeting of the Board of Health held May 28th, reports were submitted by Dr. Biggs and by Dr. Lederie, chemist to the Board, which showed that there was no contamination of the water from the cause mentioned. It is interesting to note that while, according to Dr. Biggs's examinations, the water taken from Haines' Pond, where the presence of the dead fish first excited alarm, showed 182 colonies of bacteria, and the water from Sodom Reservoir, 384 colonies, a sample of water drawn from a hydrant just outside the Board of Health Building, on Mulberry Street, showed no less than 520 colonies of bacteria.

Miscellaneous.

RETROGRESSIVE LEGISLATION IN REGARD TO MASSACHUSETTS BOARDS OF HEALTH.

THE following comments appeared in the *Boston Herald*, of May 25th:

"In the year 1797 a law was enacted in Massachusetts providing for the election of boards of health in towns. By an amendment which was made twenty years later it was further provided, that, if any town failed to elect such a board, 'the selectmen shall be the board of health.'"

"By this wise enactment, towns in Massachusetts have, for nearly a century, had some provision for boards of health; and, for nearly eighty years of that period, such a board has been in actual existence in every town in the Commonwealth, to which the people had the right to look for sanitary protection."

"Let us now examine the legislation of 1894 upon this subject. By the provisions of Chapter 218 of the Acts of the present year, the Acts of 1797 and 1817 are repealed so far as all towns having more than 2,000 inhabitants in each are concerned, and a board of health may or may not exist, in accordance with the varying whims of the voters of such towns. If the town does not elect a board of health, then, under the present law, such town is entirely without any local sanitary protection — a condition of affairs which has not existed for at least three-quarters of a century."

"In Section 2 of the same Act, provision is made

for the election of a board of health in every town having a population of less than 2,000, the old provision being here retained, that if a board is not chosen, 'the selectmen shall constitute such board of health.' By this provision it appears that each one of the small towns must have a board of health of some sort, while in the large towns the law is permissive only.

"Now it is nothing less than a sanitary axiom that increasing density of population requires the enactment of better sanitary laws for the protection of the people; and since the population of the State has increased from about 400,000 in 1797 and a half-million in 1817 (the date of enactment of the early laws upon the subject) to two and one-half millions at the present time, and, since this increase has been mainly in those towns which have populations of more than 2,000 in each and not in the small towns, the legislation in this direction ought to be in the line of improvement and not of retrogression. Measures ought, therefore, to be taken to remedy this defect before the close of the present session."

MR. GLADSTONE'S TRIBUTE TO SIR ANDREW CLARK AND THE MEDICAL PROFESSION.

A LARGELY attended public meeting was held in London recently to take definite action upon the memorial to Sir Andrew Clark. The chief address was made by Mr. Gladstone, who paid a most eloquent tribute to his late physician and to the whole medical profession as well. He said:

"The profession itself, is one with regard to which it is impossible, I think, not to be conscious that its position in our generation, and in some generations previous, has been a position continually advancing and continually widening. The other learned professions undoubtedly had a start of the medical profession. Four or five hundred years ago property was of more worth than human life and physicians were little heard of. But the position of the medical profession to-day is becoming one of vital and commanding interest to the whole of society, and I anticipate that that interest must continue. While wealth increases, while inventions and discoveries increase, wants will increase and enjoyments will increase; and, in connection with those wants and enjoyments there will, I fear, be a corresponding increase of infirmity and disease, and the medical profession braces itself to grapple with the situation which has been created, and continually advances in knowledge, credit and importance. My own life has been long enough to enable me to witness, and in some degree to measure, the change that has taken place. I have had the good fortune of knowing many eminent and distinguished men in the profession during the last threescore years, and I have seen also a great change in capacity, in attainments, and in competency to deal with the difficult, the almost insoluble, problems that are continually presenting themselves to the mind of the medical man.

"It appears to me that it was eminently desirable that, in a time like this, a man such as Sir Andrew Clark should rise to the head of his profession. For, after all, we require something more than knowledge, something more than skill. We require great devotion to the purposes of the profession; and that devotion never, I think was exemplified in a more remarkable manner than in the career of Sir Andrew Clark. He loved his profession with his whole heart and soul.

While engaged in that profession he loved it not only with sincere and cordial but with chivalrous devotion. We need not say that the age of chivalry is altogether passed so long as we have among us men of the type of Sir Andrew Clark.

"I think the profession has done well in taking by common consent Sir Andrew Clark as the typical man, the representative of all that is best and noblest in the profession and its purposes. Others may judge better than I can of his scientific ability. What I have seen is his patience, his thoroughness, and his absorption in the care of his patient as if that one case was all with which he had to occupy his mind. I have had to note in my own instance a warmth of friendship and assiduous prosecution of the task of watching my health which I know not how adequately to describe. Although he was a much younger man than I, yet he followed me from month to month and week to week with something that resembled paternal affection. I am sure that whatever happens; whatever may have been the past advances of the medical profession, and they are great; whatever may be the future advances of that profession, and they will be greater still, — there will never come a time when the profession will not be justly satisfied, and glad to have recorded upon its annals, a name such as the name of Sir Andrew Clark."

Correspondence.

"RESERVING THE CLAIM OF EXEMPTION FROM REGISTRATION."

BOSTON, June 4, 1894.

MR. EDITOR:—In the *Boston Medical and Surgical Journal* of May 24th, a correspondent suggests correctly, that members of our State Society, by its act of incorporation, have a complete license to practice without registering under the proposed new law. Incomplete as this law may be, a refusal to register might, by some, be construed as showing a disposition to obstruct any legal regulation.

I will mention a way of registering, and at the same time of reaffirming the old corporate right. It was suggested by an eminent attorney, and adopted by several physicians in regard to a law for regulating a specialty, a few years ago. It is to write before or over the signature, the phrase: "Reserving the claim of exemption from registration."

Very truly yours,
J. L. W.

METEOROLOGICAL RECORD.

For the week ending May 26th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Deaths reported 2,339: under five years of age 829; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fever) 329, acute lung diseases 307, consumption 262, diphtheria and croup 152, scarlet fever 41, diarrhoeal diseases 34, measles 30, whooping-cough 27, typhoid fever 19, cerebro-spinal meningitis 9, erysipelas 6, small-pox 5, malarial fever 4.

From measles Brooklyn 10, New York 8, Cleveland 6, Philadelphia 3, Fall River 3, Nashville 1. From whooping-cough New York 9, Boston 5, Brooklyn 3, Washington and Cleveland 2 each, Cincinnati, Charleston, Fall River and Salem 1 each. From typhoid fever Philadelphia 6, New York 3, Washington 2, Brooklyn, Boston, Cincinnati, Cleveland, Charleston, Lowell, North Adams and Woburn 1 each. From cerebro-spinal meningitis New York 5, Cleveland 2, Lynn and Brockton 1 each. From erysipelas Philadelphia, Boston, Cleveland, Lowell, Haverhill and Northampton 1 each. From small-pox New York 4, Washington 1.

In the thirty-three greater towns of England and Wales with an estimated population of 10,458,442, for the week ending May 19th, the death-rate was 17.1. Deaths reported 3,426: acute diseases of the respiratory organs (London) 234, measles 257, whooping-cough 112, diphtheria 72, scarlet fever 37, diarrhoea 37, fever 22, small-pox (London, West Ham and Birmingham 3 each, Manchester 2, Wolverhampton and Oldham 1 each) 13.

The death-rates ranged from 7.9 in Croydon to 22.2 in Norwich; Birmingham 18.6, Bolton 15.4, Cardiff 15.5, Gateshead 15.5, Hull 15.9, Leeds 16.2, Leicester 15.0, Liverpool 21.8, London 17.5, Manchester 17.4, Newcastle-on-Tyne 16.8, Nottingham 20.1, Portsmouth 9.5.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 26, 1894, TO JUNE 1, 1894.

FIRST-LIEUT. WILLIAM H. WILSON, assistant surgeon, now on duty at Fort Leavenworth, Kansas, will proceed at once to Camp Merritt, Montana, and report for assignment to temporary duty at that post.

NEW HAMPSHIRE MEDICAL SOCIETY.

The one hundred and third anniversary meeting will be held at G. A. R. Hall, Concord, Monday and Tuesday, June 18 and 19, 1894.

MONDAY, JUNE 18TH.

Medical papers and communications: "On the Prevention of Communicable Diseases," D. Edward Sullivan, M.D., Concord. Discussion opened by Wm. Child, M.D., New Hampton. "Sleep, How Best Induced in Certain Pathological Conditions," J. B. Raynes, M.D., Lebanon. Discussion opened by W. T. Smith, M.D., Hanover. "On Puerperal Infection," J. Elizabeth Hoyt, M.D., Concord. Discussion opened by John W. Parsons, M.D., Portsmouth. "Retrospective Glances," A. G. Straw, M.D., Manchester. "Report on Bone Surgery," D. S. Adams, M.D., Manchester. Discussion opened by Robert Burns, M.D., Plymouth, who will also report a case of "Exsection of the Astragalus." "Report on Empyema," William H. Lyons, M.D., Manchester. Discussion opened by G. C. Blaisdell, M.D., Contoocook. "On the Differential Therapeutics of Strophanthus and Digitalis," W. K. Wadleigh, M.D., Hopkinton. Discussion opened by Henry Dodge, M.D., Webster.

There will be a meeting of the Council at 7.30 P. M.

After the meeting of the Council (probably about 8.30 P. M.), the members of the association residents of Concord will welcome the Society in the G. A. R. Hall, and will entertain the members and their friends with a lecture on "Potable Water," by Prof. E. J. Bartlett, of Hanover, after which there will be a meeting of the alumni of Dartmouth Medical College.

TUESDAY, JUNE 19TH.

"On the Pathology and Methods of Treatment of Hypertrophic and Atrophic Rhinitis - with Especial Reference to the Work of the General Practitioner," Albert Pick, M.D., Boston, Mass. "On Laceration of the Cervix Uteri," F. A. Stillings, M.D., Concord. Discussion opened by M. W. Russell, M.D., Concord. "Glimpses of Fifty Years in the Medical Profession," Cyrus K. Kelley, M.D., Plymouth. "On Sanitation in Mexico," G. P. Conn, M.D., Concord. "On the Importance of the Early Recognition of Certain Diseases of the Eye by the General Practitioner, with Suggestions Regarding Management," H. W. D. Carville, M.D., Manchester. Discussion opened by Geo. Cook, M.D., Concord. President's Address, Samuel P. Carbee, M.D. Introduction of officers.

The Anniversary Dinner will be served at the New Eagle Hotel at 1 P. M.

EXHIBIT. - Exhibitors will use the banquet-room adjoining the assembly-hall, which will be in charge of Dr. Day, of the Committee of Arrangements.

GRANVILLE P. CONN, M.D., Secretary, Concord, N. H.

SOCIETY NOTICE.

MASSACHUSETTS MEDICO-LEGAL SOCIETY. - The annual meeting of the Society will be held on Tuesday, June 12, 1894, at 1 o'clock, P. M., in the hall at 19 Boylston Place, Boston.

The usual business of the annual meeting will be transacted, and the following communications will be presented:

1. "What Cases Shall the Medical Examiner View?" J. A. Mead, M.D.
 2. "Suicide or Homicide? A Medico-Legal Diagnosis." C. S. Holden, M.D.
 3. "Comments on a Case of Homicide." A. H. Hodgdon, M.D.
- Fellows of the Massachusetts Medical Society are invited to be present.

Z. B. ADAMS, M.D., President.

F. W. DRAFER, M.D., Recording Secretary.

Addresses.

THE LEGISLATIVE CONTROL OF MEDICAL PRACTICE.¹

BY REGINALD H. FITZ, M.D., BOSTON.

MR. PRESIDENT AND FELLOWS OF THE MASSACHUSETTS MEDICAL SOCIETY:—With the advancement of learning, and the progress of civilization, it has been found necessary for those in authority to exercise more and more control and restraint upon such as are engaged in the practice of medicine.

As it became evident that the name of physician or surgeon was offered in excuse for the grossest ignorance or neglect, or to incite the actual destruction of human life, laws were passed to aid the victim of malpractice, and to punish the criminal abortionist.

When it appeared that sane persons were sometimes, and perhaps for the worst of motives, placed under restraint, justified only in the case of lunatics, a physician's certificate became necessary for the commitment of the insane.

The public has learned that the surest way of controlling the ravages of contagious disease is by the isolation of the earliest cases, and that for the protection of the well, even arbitrary measures of isolation may be found necessary. It, therefore, makes it the duty of the physician to notify immediately the proper authorities when he knows that he has seen a case of cholera or small-pox, diphtheria or scarlet fever, that the community may rest assured that suitable measures are being taken to protect the healthy. Elaborate and costly quarantine methods, useless without the services of intelligent, skilful and especially trained physicians, are established for the same purpose. In addition, vaccination, compulsory if need be, must be guaranteed by the physician to promote the same object.

He must make a return of the birth at which he assists, and must furnish a certificate of the cause of death. When there is reason to suppose that the latter has occurred under suspicious circumstances, the community orders that these shall be satisfactorily investigated by physicians of its own choice, if it sees fit.

The people thus demand, and submit with more or less eagerness or readiness to certain attempts at regulating the practice of medicine. They admit the necessity of the control, and they require qualifications, which only combined intelligence, education and honesty can provide. They seek for them in physicians, and expect the latter to possess them.

It is well recognized among those possessing the best opportunities for judging that patients are at times treated with reckless ignorance or negligence, and die in consequence; but no verdict of homicide is rendered. Ignorant and unskilful persons have often assumed to treat patients in a medical way, have caused injury, and have not suffered civil damages. Equally ignorant and unskilful pretenders to practice do not know the symptoms of contagious disease, do not suspect its presence, make no report to the proper authorities, suggest no isolation, and are the direct cause of the spread of diphtheria, of scarlet fever and the like from house to house and from district to district. The physician's record of the cause of death not infrequently conceals criminal abortion, sometimes manslaughter,

and is often indicative of such ignorance as to be wholly worthless.

Nowhere in the Union is the possibility of these evils greater than in Massachusetts. In this State any one who chooses may practise medicine. He has but to announce himself a physician and he becomes one. He may assume a title to which he has no claim, and may place a forged certificate upon his walls. He may advertise himself a graduate of any institution he prefers; may claim to have accomplished any number of cures of what have been pronounced incurable disease. He may promise preventives and specifics against any and all maladies; he may publicly announce the most glaring untruths—all for the sake of deceiving and fleecing a credulous public—and the law cannot interfere with his actions. We are repeatedly told that our law makes no distinction between the various schools of medicine, or between the various kinds of practitioners. Members of this Society, homœopaths, electricians, clairvoyants, faith-curers, mind-healers, Christian scientists, are alike legally qualified as physicians. Since the people demand, at times under penalty, services from physicians which only intelligence, education and honesty can supply, and since it is a matter of common knowledge that many stupid, ignorant, and dishonest pretenders to practise exist, it is clearly the duty of the State to discriminate between the two, to legally qualify those who deserve the confidence of the people, and to disqualify those who are often the abettors of crime, the victimizers of youth and the constant source of danger to every member of the community.

The object of such legislation is unmistakable. It is for the protection of the entire community, but especially for that portion of it less favored by education or fortune, by experience or knowledge. Its design is to promote their health, happiness and prosperity by giving them a means of deciding to whom they shall apply for intelligent, skilful and honorable aid in the time of need, often so sudden and unexpected in its coming. It enables them to determine by the only feasible means who is educated and who is not, what physicians are deserving of esteem and consideration, and what practitioners are pretenders, sometimes honest, perhaps, usually specious and presumptuous, and generally wofully ignorant.

To license the physician does not imply that he is not to treat his patients in any way he or they may prefer. It should mean that he is to show, before being allowed to treat disease, that he can discriminate between those which are dangerous to the individual and those which are a source of peril to the public. The former may, perhaps, take his life in his own hands, but he should not be allowed to imperil that of his neighbors.

Such a law offers no protection to the licensed physician, who can take care of himself. His education and opportunities have taught him to whom he is to go for suitable advice. Nor does it favor his occupation, since the more unskilful or negligent treatment in the community the more the demand for the services of the skilled and upright physician.

The many who ask for this protection and appreciate its need, suffer from the few, who, ignorant of the necessity, are deceived by false pretences, or are blindly devoted to a theory.

The numerous attempts at the legislative control of medical practice which have been made in the past

¹The Annual Discourse before the Massachusetts Medical Society, delivered June 13, 1894.

twenty-five years show that these aims may be accomplished to a certain extent. Every effort meets with opposition, and it is to the nature of the latter and the arguments it offers that your attention is now requested.

Such opposition is diverse and its motives extremely mixed.

On the one hand is to be found the entire class of those likely to be shown ignorant, unskilful, dishonest or corrupt. These are encouraged and supported by those whose occupation it is to systematically oppose all antagonistic legislation — for a consideration. On the other hand we see intelligent theorists and educators, at times leaders in thought and morals, who object to the infringement of personal rights, or the exercise of paternal care by the government. With these are associated respected leaders of the profession who have vigorously and persistently struggled for the highest possible standard of medical qualification, and oppose or discourage all measures which fall short of it. Thorough supporters of some medical legislation, they are determined opponents of all plans of which they cannot approve. These leaders of the opposition are followed by a considerable number of citizens, insufficiently educated, often ill-balanced, and frequently influenced by arguments of the most specious and superficial character.

In general the grounds for the opposition to the legislative control of the practice of medicine are the following assertions:

It invades personal liberty.

It legislates for a class.

It tends to obstruct the progress of therapeutics.

It is unnecessary.

It is not wanted.

It has proven a failure.

Let us consider these somewhat in detail:

It is claimed to be a violation of personal liberty, since it denies to some their right to pursue the occupation they desire and to others the right to select as medical adviser any person they please.

Herbert Spencer is usually quoted as the leading exponent of this view. He says:²

"If it is meant that to guard people against empirical treatment, the State should forbid all unlicensed persons from prescribing, then the reply is, that to do so is directly to violate the moral law. . . .

"The invalid is at liberty to buy medicine and advice from whomsoever he pleases; the unlicensed practitioner is at liberty to sell to whomsoever will buy. On no pretext whatever can a barrier be set up between them without the law of equal freedom being broken; and least of all may the government, whose office it is to uphold that law, become a transgressor of it.

"Moreover this doctrine, that it is the duty of the State to protect the health of its subjects, cannot be established, for the same reason that its kindred doctrines cannot, namely, the impossibility of saying how far the alleged duty shall be carried out. Health depends upon the fulfilment of numerous conditions — can be 'protected' only by ensuring that fulfilment; if, therefore, it is the duty of the State to protect the health of its subjects, it is its duty to see that all the conditions of health are fulfilled by them . . . enact a national dietary; prescribe so many meals a day for each individual; fix the quantities and qualities of food, both for men and women; state the proportions of fluids, when to be taken, and of what kind; specify the amount of exercise, and define its character; describe the clothing to be employed; determine the hours

of sleep, allowing for the difference of age and sex . . . and to enforce these regulations it must employ a sufficiency of duly qualified officials, empowered to direct every one's domestic arrangements."

It is to be remembered that this argument of Mr. Spencer is directed against placing restrictions upon "empirical treatment," which is regarded as a violation of the moral law. But let us quote further:³

"Let it be conceded that very many of the poorer classes are injured by druggists' prescriptions and quack medicines. . . .

"Inconvenience, suffering and death are the penalties attached by nature to ignorance, as well as to incompetence — are also the means of remedying these. . . . All means which tend to put ignorance upon a par with wisdom, inevitably check the growth of wisdom. Acts of parliament to save silly people from the evils which putting faith in empirics may entail upon them, do this, and are therefore bad. Unpitiful as it looks, it is best to let the foolish man suffer the appointed penalty of his foolishness. For the pain — he must bear it, as well as he can; for the experience — he must treasure it up, and act more rationally in the future."

This argument of more than forty years ago is persistently brought forward whenever the question is raised of the control of medical practice by the State. It is usually overlooked that it relates especially to prescribing, whereas the practice of medicine includes other considerations than that of providing means of treatment.

Despite the reasoning of Mr. Spencer the government finds it necessary to take certain steps, theoretically objectionable, for the protection of the health of the individual. It does not prescribe the number of meals per day, or the proportion of fluids and solids, the amount and character of the exercise, the kind of clothing and the hours of sleep. It does, however, insist that food offered for sale shall be unadulterated and wholesome; that water-supplies shall be uncontaminated; that noxious trades shall be rendered, as far as possible, harmless; that clothing shall be made under certain conditions. The State cannot protect the health of its subjects in every respect; but it everywhere endeavors to accomplish something. Even Mr. Spencer may be quoted in approval:⁴

"He who contaminates the atmosphere breathed by his neighbor, is infringing his neighbor's rights . . . and in the discharge of its functions as protector, a government is obviously called upon to afford redress to those so trespassed against."

Professor Huxley's name is usually coupled with that of Mr. Spencer as an opponent to placing restrictions upon the practice of medicine. His words are as follows:⁵

"In my judgment the intervention of the State in the affairs of the medical profession is to be justified . . . simply and solely upon the ground that the State employs medical men for certain purposes, and as employer, has a right to define the conditions on which it will accept service. It is for the interest of the community that no person shall die without there being some official recognition of the cause of his death. It is a matter of the highest importance to the community that in civil and criminal cases, the law shall be able to have recourse to persons whose evidence may be taken as that of experts; and it will not be doubted that the State has a right to dictate the conditions under which it will appoint persons to the vast number of naval,

² Social Statics, 1851, 377.

³ Op. cit., 372.

⁵ Nineteenth Century, 1884, xv, 228.

Social Statics 1851, 373.

military and civil medical offices held directly or indirectly under the government. Here, and here only, it appears to me, lies the justification for the intervention of the State in medical affairs."

Although this plea that the regulation of the practice of medicine is a violation of human rights has regularly been brought forward for the purpose of exciting sympathy, it has repeatedly been declared by the courts, except in New Hampshire, to be invalid.

It is best answered in the words of Judge Williams :

"In a certain sense it is true that every man has a natural right to follow out the bent of his inclination, and be a clergyman, a lawyer, a doctor, a scavenger, a peddler, an auctioneer, just as he may choose. But, it is not true that a man can practise any one of these professions or occupations except he does it upon such terms as the law imposes, and the law can impose just such terms upon any one of these professions or employments as the legislators in their discretion deem best for the interest of the community. . . .

"The right to practice medicine is a mere statutory privilege, subject to be changed at any time by the legislature."

It is claimed to be class-legislation, producing a monopoly, and, therefore, unconstitutional. We have again a statement, which is offered to excite sympathy, although its illegality has been demonstrated. It is everywhere recognized that legislation designed for the welfare of the people is the duty of the State, and is approved, if not demanded, by the public. The only question is to what extent shall such class-legislation be carried. The people alone are to decide. Licenses are given to peddlers, plumbers and apothecaries, to dealers in liquor, milk and oleomargarine. Pilots must show a familiarity with the dangers to navigation in the waters through which they undertake to guide vessels, before they can be permitted to take charge of them. Surgeons must be examined as to their medical and surgical knowledge before they can be appointed to the service of the militia. These are but a few of the illustrations that such class-legislation as is contemplated in the licensing of physicians is taking place constantly and with uniform approval. It does not create a monopoly, since it does not limit the practice of medicine to any particular sect or school. Any person can still become a physician by taking the necessary steps to secure a proper preparation for an occupation which is generally conceded to be one of great responsibility, and one demanding a various training. What is open to all is no monopoly. But this objection, too, has been definitely settled by the decision of the Supreme Court of the United States, given by Mr. Justice Field in the case of *Dent v. West Virginia*.⁷ According to him

"there is no arbitrary deprivation of such right where its exercise is not permitted because of a failure to comply with the conditions imposed by the State for the protection of society. The power of the State to provide for the general welfare of its people authorizes it to prescribe all such regulations as, in its judgment, will secure or tend to secure them against the consequences of ignorance and incapacity at well as of deception and fraud. . . . The nature and extent of the qualifications required must depend primarily upon the judgment of the State as to their necessity. . . .

"We perceive nothing in the statute which indicates an intention of the legislature to deprive any one of his right. No one has a right to practice medicine without having the necessary qualifications of learning and skill;

and the statute only requires that whoever assumes, by offering to the community his services as a physician, that he possesses such learning and skill, shall present evidence of it by a certificate or license from a body designated by the State as competent to judge of his qualifications.

"There is nothing of an arbitrary character in the provisions of the statute in question; it applies to all physicians, except those who may be called for a special cause from another State; it imposes no conditions which cannot be readily met."

We are told that a law to license medical practitioners will obstruct the progress of therapeutic knowledge, since certain so-called healers and curers will refuse to be examined for a license. This class is likely to include the hydropaths, psychopaths, nature-paths, omnipaths, mind-healers and faith curers, spiritualists, mesmerists and Christian scientists, botanic, hygienic and Indian physicians, the seventh son of a seventh son, and the retired clergyman whose sands of life have nearly run out, and the like.

They will refuse to be examined, since they are conscious of their inability to pass an examination, or they may claim that they will suffer a loss of therapeutic power by acquiring knowledge of the anatomy and physiology of the body or of the symptoms and diagnosis of disease. These people should not be licensed unless they submit to the requirements which are deemed sufficient to test the qualifications of physicians. There need, then, be no interference with such therapeutical experiments as they and their patients see fit to carry on, at their own exclusive risk.

The demand for such persons, under some title or other, will always exist. There are many worthy citizens, some of a high degree of intelligence in many things, who firmly believe that most remarkable and wonderful cures have been accomplished by such "healers." They are told, and are willing to believe, that the latter possess the gift of healing, and have "divined" the successful treatment of disease. Such miraculous cures have been reported in all ages, but the methods of their accomplishment have proven no commendable additions to therapeutic knowledge. They are recognized as dependent upon mental peculiarities, by no means to be encouraged, of the patient, and equally striking and frequently objectionable characteristics of the practitioner.

We are told that the latter will refuse to be examined because he may lose his power. It is to be remembered that Christian scientists are not the only practitioners who have obtained successful results by the use of faith. Dishonest charlatans have been as fortunate as religious enthusiasts, and eminent physicians have proven quite as successful as either. Mental therapeutics may accomplish wonderful results in certain instances, but the ability to use them is in no respect limited to persons ignorant of any claim to medical knowledge. It may well be admitted that there are some patients who will recover under certain therapeutists, but not when licensed physicians attempt their treatment. It is unfair to deprive such individuals of this possibility unless there is a risk to others.

Even Mr. Spencer recognizes the importance of restraining those "who contaminate the atmosphere," and no person should be allowed to undertake the treatment of the sick without previously having given evidence of a sufficient knowledge of the means of recognizing contagious diseases and the measures to be adopted to check their dissemination.

⁷ Rep. Ill. State Board of Health, 1885, vii, 432.
⁸ 129 United States, 114.

There are those who claim that were there no other objection to the further control of medical practice it is unnecessary, since it would add but an infinitesimal degree of security to the citizen's chance of being faultlessly treated when sick, and the people are already protected by the existing laws against malpractice and manslaughter.

No honest and intelligent physician of practical experience claims to treat faultlessly a sick person. No sensible physician, familiar with the seats and causes of diseases, believes that it ever will be possible to always treat faultlessly the sick person, provided it is meant by this phrase to cure him of his disease. But the treatment of the sick person is but a part of the doctor's duty. To enable his patients to avoid disease, to prevent them from becoming dangerous to others, are not the least important parts of his occupation. Education alone, in addition to intelligence and honesty, can enable him to promote these aims.

The practise of Massachusetts courts in medical cases during the greater part of the present century was based on the decision of Chief Justice Parsons in 1809,⁸ that if the patient's death is the result of treatment honestly administered, the person prescribing is not guilty of manslaughter. It is only within the past ten years that this decision has been reversed⁹ by the declaration of Judge Holmes that one who practises with reckless ignorance or negligence is liable for homicide, and for civil damages if he causes injury by ignorant or unskilful practice.

The number of cases of death due to the gross ignorance or negligence of the charlatan is unknown. Some are probably familiar to many members of this Society. I merely allude to the statement of the court that Thomson, who gave his name to Thomsonianism, without reasonable doubt caused the death of his patient by unskilful treatment. That Franklin Pierce was the cause of his patient's death by ordering the application of flannels saturated with kerosene oil for some three days. That a barber in Illinois, by the unscrupulous methods of the quack, obtained a considerable practice, and caused "the brutal butchery of a mother in labor and her unborn offspring."¹⁰

Other instances, occurring in his own experience, are mentioned by the medical examiner for Suffolk County, Dr. F. W. Draper, in his argument before the Public Health Committee of the Legislature, February 14, 1894.

Dr. F. B. Harrington, of Boston, informs me of a poor woman who was suffering from copious and continuous hæmorrhages from uterine cancer. These were controlled in accordance with his advice. She later came under the care of a Christian scientist, who told her there was nothing the matter, and that she might go out and pursue her daily occupation. The bleeding returned, but the advice to go about was persisted in. A hæmorrhage took place while she was away from her home and caused her death shortly after her return. Similar illustrations of death following the gross ignorance of persons claiming to cure disease might be produced almost without limit, and the existing laws fail to prevent them.

But it is claimed, if the person is injured as a result of negligence or lack of skill, a suit for damages

may be brought. As a rule such cases do not come to trial. Those which are brought before a jury are usually directed against educated physicians of means for various motives. The hospitals of every large city are constantly resorted to by unfortunates who have been induced to apply to ignorant and pretentious charlatans for medical or surgical aid, and have suffered grievous injury from following their advice. If the sufferer realizes the cause of his misfortunes, he may be unable to secure the services of counsel. If he should be successful in this effort he usually recovers nothing, since the charlatan either has no visible means, or leaves the State in time to escape an unfavorable verdict. Much more often he suffers in ignorance of the cause of his suffering.

Not only are the laws against manslaughter and malpractice insufficient to protect the community, but those intended to guard against the spread of contagious diseases are alike ineffective. The ignorant pretender, under whatever title he or she may appear, often does not recognize the nature of the contagious disease. No suggestion is made of isolation. Well children are allowed to play with the sick. All are permitted to go to school, and the outbreak of scarlet fever or diphtheria is thus promoted, which could have been avoided by the intelligent precautions of an educated physician. I have before me the advertisement of a person employed in a street-car, announcing "Diphtheria cured in all stages." Cases were taken to him for treatment and were not reported to the Board of Health. The law concerning the notification of contagious diseases could not apply to this person, since he did not call himself a physician; neither was he a householder, and he could have pleaded ignorance of the nature of the malady. The cases under his treatment which were about to die were referred, at the last moment, to physicians who were then called upon to give such aid as was possible. Existing laws do not protect the community from such persons as these.

We are told that the legislation is not wanted, since the people do not ask for it. The history of medical legislation in the various States of the Union furnish direct evidence to the contrary. Appeals are made by clergymen, lawyers, authors, physicians and public-spirited men of every degree. Physicians, it is true, as a rule, take the initiative, since the evils resulting from the ignorance or lack of skill of the pretender are usually first brought to their notice. The grievously sick or dying victims of the abortionist, the moribund patient deceived by the promises, or injured by the statement of the charlatan, eventually seek aid from the educated physician in good standing, often at a time when death is but a few hours removed, or permanent deformity has been made a necessity, or conditions often bordering upon insanity have been reached.

It is this experience of the doctors which has opened the eyes of the people, and it is the enlightened common-sense of the latter which has decided upon the need of the regulation of the practice of medicine throughout nearly all the United States.

Finally, we are told that the State control of medical practice has proven a failure. At the present time some sort of law intended to regulate the practice of medicine exists in nearly every State and Territory of the Union. These laws differ widely in

⁸ Commonwealth v. Samuel Thomson, 6 Mass. Rep., 124.

⁹ Commonwealth v. Franklin Pierce, 128 Mass. Rep., 166.

¹⁰ Rep. State Board of Health, Ill., 1884, vi, 10.

air scope and in their results, but all have the same end in view — the protection of the people. As some have failed to produce the desired result, suitable amendments have been made. Some of the most recent laws are those which promise to be the most efficient, and it would indeed be astounding were a series of failures likely to act in favor of a renewal of the same undertaking. On the contrary, the failure of the earlier attempts at medical legislation has led to the avoidance of the causes of failure, and the reports from various States give encouraging evidence of what has been accomplished.

(To be continued.)

THE INFLUENCE OF ANIMAL EXPERIMENTATION ON MEDICAL SCIENCE:

ABSTRACT OF THE PRESIDENT'S ADDRESS BEFORE THE CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS, AT ITS THIRD TRIENNIAL MEETING, WASHINGTON, D. C., MAY 31, 1894.

BY ALFRED L. LOOMIS, M.D., OF NEW YORK.

THE specific problems with which medical science deals are questions of the relative influence of multiple forces on the production of given results. Only the deepest ignorance can fail to recognize that the forces concerned in the simplest change of inorganic nature are so numerous and their relations so complex that they defy recognition under uncontrollable conditions, while in the organic world the task is even more hopeless. Experimentation, therefore, in which one or more of the involved forces can be controlled, becomes an absolute necessity in all scientific investigation. However clear the mental analysis, however accurate the logical demonstration from cause to effect, it is possible by experiment alone to prove that no involved force has been overlooked. Is it not strange that medicine should be denied the right to follow those imperative methods of scientific research which are so unquestionably accorded to every other science? It is not a little surprising that men with an appreciation of the necessity of experimentation should for so long have preferred to be its subjects, and that even to-day so many refuse to yield the place to animals. For example, in widespread epidemics we note the effects of an infection on perhaps half a million of human beings, with a great sacrifice of human life. On the other hand, we study in laboratories the cause of the epidemics with a comparatively small sacrifice of animal life.

In entering upon the consideration of this subject the author fearlessly laid down this proposition: Every distinct advance, every established principle, and every universally accepted law of medical science has been in the past and will be in the future the direct, if not the immediate result of animal experimentation. He then passed to a review of some of the obvious and conclusive proofs of this proposition.

It is not too much to claim that during the latter half of the present century the results obtained from experiments on animals have done more than all the observations of the preceding centuries to raise medicine from conditions of vagueness to conditions of exactness. From the time of Aristotle, who proved that the blood, brain and spinal marrow in animals have no sensation, down to the present day, animal experimentation has been practised by all investigators who have

gained any definite knowledge of the more important phenomena of animal life.

Galen must be regarded as the pioneer in this line of investigation. By his experiments on living animals he showed that arteries contain blood, that the lungs passively follow the movements of the chest, and that the diaphragm although the most important is not the only muscle of respiration. Further, by section of the spinal-cord and of the recurrent laryngeal nerve, he demonstrated the nervous control of the voice and explained the mechanics of respiration. He also advanced the knowledge of the functions and movements of the alimentary canal and laid the foundation of our knowledge of the functions of the brain and spinal-cord. The results of his experimental work are now as conclusive as when first made, and are the only part of his vast labors which have stood the test of modern investigation.

From Galen's time to Harvey's great discovery, little experimental work was done; and during this time medicine ceased to advance. Harvey's demonstration of the circulation of the blood in 1620 rests entirely on animal experimentation, as is shown by his writings.

The next series of important investigations on animals were applied by Galvani and Volta to the nervous system.

In 1664 Robert Hook, by inflating the lungs of animals by means of a bellows, demonstrated artificial respiration. The experiments of Boyle and of Priestly in the seventeenth century laid the foundation of our knowledge of the respiratory process.

The injection of fluids into the blood-vessels of animals was first done by Dr. Christopher Wren. In 1666 Richard Lower performed the first transfusion, and the following year Dr. Denis performed the same experiment on man.

Haller, in the middle of the eighteenth century, proved that all motion in the human body proceeds in great measure from the brain and spinal-cord. He also demonstrated that irritation of the peripheral end of a severed nerve produced contraction in the muscle to which it was distributed. This was followed by the experiments of Sir Charles Bell. At the beginning of the present century Magendie demonstrated the difference between the anterior and posterior roots of the spinal-cord. His experiments on animals by the injection of various medicinal substances enabled him to lay the foundation of the doctrine that remedies exert their action upon special structures and organs. In this line of work he was followed by Claude Bernard. It is perhaps a conservative statement, that, excluding the medicinal foods, ninety per cent. of all our medication is made definite and valuable by this principle alone. Magendie, Bernard and Loget established by their experiments the doctrine of recurrent sensibility, which was followed by the discovery of Marshall Hall of reflex action of the spinal-cord. The doctrine of vaso-motor action was practically demonstrated by Bernard's experiments.

John Hunter, in 1785, by his experiments on dogs, established the fact that injuries to healthy arteries were soon repaired, and that ulceration after ligature occurred only when the vessel was diseased. The experiments led him to apply ligatures for the cure of aneurism to healthy portions of the arteries. Hunter first learned by experiment on pigeons and young pigs that the growth of bone was from the periosteum.

As we witness some capital operation performed at the present day without pain, almost bloodless, followed neither by fever nor suppuration, we may ask how far these results are due to experimentation on animals. The effect of chloroform was discovered through experimentation on the ant. Simpson practised and perfected his use of chloroform on animals before he placed his first patient in a state of anesthesia. That other great alleviator of pain was first practised on dogs.

These results are sufficient to exalt animal experimentation to the first place, as a means of scientific advancement.

The first important step in the field of etiology based on animal experimentation was made in 1850, when it was proven that splenic fever could be communicated from animal to animal by inoculation, and the first hint of bacteriological study was given by the discovery constantly in the blood of these animals of little thread-like bodies.

About the same time Virchow made his observations on trichinosis. M. Viyaman inaugurated an important era when he established the fact that tuberculosis was an infectious disease. The invaluable studies of Pasteur introduced us into a new world of knowledge. He not only obtained pure cultures of organisms, but also studied their life-history and placed bacteriological science on a firm basis. The crowning glory of Pasteur's work came with the discovery of the attenuation of bacterial toxic products. It is not possible to point to a work of richer or grander promise, yet it is a work that was possible only by experiments on living animals. The application of Pasteur's doctrine by Mr. Lister to the antiseptic treatment of wounds has been a full confirmation of this principle.

The discovery of the bacillus tuberculosis by Koch marks another brilliant epoch in medical science.

Within the past two decades animal experimentation has accomplished more in the field of cerebral localization than all the preceding centuries of carefully recorded cerebral symptoms studied in the light of post-mortem investigation. It has opened a new field of operation.

From this history, it seems evident that most if not all of the real advances in medicine have been made possible through experimentation. This review of what our profession has done is not a plea for mercy — it is a cause for pride. So long as the moral and spiritual development of mankind remains the supreme purpose of creation, medical science can claim equal honor with the science of God, and in the conflict with physical evil must be the first to meet the foe. Until Infinity repeals the edict which gave man power over all created things, the right to claim the services of the brute can never be denied him who devotes his life to the service of mankind. We glory in our experimental work because we know the tenderness of cruelty, the balm of pain, the life whose birth is only in the throes of death. From the ignorant we expect to receive only censure; but from those who in the valley of the shadow of death have learned to know what manner of men we are, I have faith to believe that the reply will come, "We have trusted you with the lives of our loved ones, we entrust to you God's dumb creatures."

THE Pope has decided that cremation, while heretical in principle, may be allowed under special conditions.

STRANGULATION OF MECKEL'S DIVERTICULUM CAUSED BY VOLVULUS OF THE ILEUM.¹

BY J. W. ELLIOT, M.D., BOSTON,
Surgeon to the Massachusetts General Hospital.

THE patient, a man about thirty years old, was brought to the accident room of the Massachusetts General Hospital, October 17, 1893. He had been sick for four days, with vomiting, chills and abdominal pain. The bowels had moved twice in the previous forty-eight hours. The temperature was 103.6°, pulse 160, respiration 35.

The abdomen was distended, tympanitic and exquisitely tender, especially to the right of, and below the umbilicus. Free fluid was evidently present in the peritoneal cavity. Under ether, a large hard mass was plainly felt in about the middle of the abdomen, just below and slightly to the right of the umbilicus. Both Dr. M. H. Richardson and I considered it a severe case of appendicitis. Dr. Richardson also kindly assisted me with the operation, which proved to be the most difficult and perplexing operation I ever saw.

The abdomen was opened by a vertical incision two inches inside the anterior superior spine of the ileum. A quantity of turbid fluid escaped. The appendix was examined, and found to be normal. On exposing the mass near the middle of the abdomen by extending the incision, it looked like a large dilated and gangrenous knuckle of intestine, but without a mesentery. It sprang from the lower part of the convex surface of the ileum, and was tightly twisted at its point of attachment to the bowel. It extended upwards into a dense mass of adhesions, and when dissected free was found to be attached to the under surface of the umbilicus. It was then evident that we were dealing with a Meckel's diverticulum in a strangulated and gangrenous condition. It was seven inches long, and about the same size as the ileum. During the dissection, the gangrenous diverticulum was ruptured, allowing the escape of a quantity of fecal-smelling fluid into the peritoneal cavity. The diverticulum was removed, and the opening in the ileum was closed with several Lembert sutures. The ileum at this point was found twisted on itself and held in this abnormal position by adhesions. The gut was not wholly obstructed by the twist. On untwisting the bowel old adhesions were found extending deep into the mesentery so as to shorten it at one point. This contraction of the mesentery seemed to have caused the volvulus of the ileum. The diverticulum having its outer end fixed at the umbilicus, was twisted and strangulated at its base by the turning over of this coil of the ileum. The gangrene of the diverticulum was most intense near the ileum, the end at the umbilicus being only moderately inflamed. This is explained by the fact that the diverticulum has its blood-supply from the mesenteric artery of the ileum.

The operation was severe, causing the pulse to rise to 180 at the end. The patient, already septic at the time of operation (unfortunately the cultures of the turbid fluid found in the abdomen were lost), died of septic peritonitis on the second day.

As is well known, Meckel's diverticulum is due to the persistence or incomplete obliteration of the vitel-

¹ Read at the Congress of American Physicians and Surgeons at Washington, May 31, 1894.

line duct. It is usually small, and has its principal interest in the fact that it not infrequently acts as a band and causes intestinal obstruction.

Dr. R. H. Fitz,³ in a very valuable paper on this subject, quotes Roth² as calling attention to the origin of retention cysts from Meckel's diverticulum. "Such cysts are divided into two classes, according as their cavity is continuous or discontinuous with that of the intestine. The wall is composed of the various layers found in the intestine." Roth describes a cyst of this kind occurring in a child one year and four months old. "It was connected with the concave surface of the ileum, near the mesenteric insertion twenty-six inches above the ileo-cæcal valve. The pedicle having become twisted, a hæmorrhagic infiltration and necrosis of the mucous membrane had occurred, also acute peritonitis."

The case here reported is unique, but this case of Roth's resembles it in several important particulars. In both cases the diverticulum was strangulated by twisting of the pedicle, and acute peritonitis followed.

These cases are sufficient to establish the fact that strangulation of Meckel's diverticulum is one of the causes of acute peritonitis. This fact has an additional interest at the present moment in that the diverticulum resembles the vermiform appendix, and the two lesions may easily be confounded, clinically, as in the present case. While the diverticulum is often without a mesentery and is therefore freer and more likely to suffer from strangulation by twisting of its pedicle, yet it not infrequently has a mesentery; in which case it must be liable to the same pathological processes (though evidently much less frequent) as the appendix. Such cases are not wanting. Fitz mentions a case reported by Dr. Beale,⁴ where acute peritonitis followed perforation of a diverticulum, in the cavity of which were a cherry-stone, the coriaceous covering of several orange-pips and other substances; and also a case of adherent diverticulum described by Houston.⁴ This diverticulum was filled with a hard matter, apparently inspissated feces. "The omentum and intestines in the neighborhood were closely joined to the tumor by adhesions, the result of former inflammatory attacks, and the woman had complained for many years before her death of occasional severe pain in the abdomen."

The symptoms of inflammation of these two intestinal pockets are the same, as they both cause peritonitis. The only points in the differential diagnosis which the writer is able to suggest, are that a history of a discharge from the umbilicus (this occurred in a case of intestinal obstruction due to diverticulum in the practice of Dr. John Homans) would suggest the presence of a diverticulum, while a history of previous attacks of pain would be significant of either an inflamed appendix or diverticulum, as, according to Fitz, "In nearly one-half the cases of vitelline remains previous attacks of pain were recorded." The presence of a tumor or tenderness near the umbilicus should favor the theory of inflamed diverticulum as against the appendix. It will be remembered that in the case here reported a distinct tumor could be felt just below and slightly to the right of the umbilicus.

The only treatment to be thought of in such cases is prompt laparotomy and the removal of the inflamed or strangulated diverticulum. The special points to be observed in the operation are the careful stitching of the pedicle, as it often opens directly into the intestinal canal; also the careful ligation of the vessels, because the diverticulum is supplied by a branch of the mesenteric artery, which is the persistent omphalo-mesenteric artery, and may be of considerable size.

SUICIDAL GUNSHOT WOUND OF THE ABDOMEN; FÆCAL FISTULA; COMPLETE RECOVERY WITHOUT OPERATION.¹

BY P. RALPH EGAN, M.D.,
Assistant-Surgeon, United States Army.

THE older surgeons looked on gunshot wounds of the abdomen with feelings akin to despair. The mortality from these injuries under the most favorable circumstances amounted to over eighty per cent. In less fortunate cases it reached a hundred per cent.

Need we wonder that after the successful cases of Kocher and Bull, ten years ago, the motto became, "Laparotomy for diagnosis and treatment." It was the inevitable enthusiasm following a new and successful method of treatment. It is now, however, beginning to be modified before the tests of experience.

In military practice the difficulty of diagnosing a perforation, and the frequent necessity for immediately transporting the patient from the seat of action, generally caused laparotomy to be deferred. It will further be necessary to differentiate as far as possible between wounds of the various parts of the intestines.

It has always been a well-known fact that wounds of the large intestine were less fatal than those of the stomach and small intestine. Even wounds of the different divisions of the large bowel give different results. Assistant-Surgeon Otis, United States Army, writes:² "While few instances are observed of recovery from gunshot wounds of the transverse colon, many were seen of survival after perforation of the cæcum and ascending portion of the bowel, and a still larger proportion of recoveries was observed in wounds of the sigmoid flexure and other parts of the descending colon. . . . Nearly all were attended by stercoral fistulæ which commonly closed after a time, without operative interference, reopening at intervals, and

² Medical History of the War of the Rebellion.

then healing permanently." He then gives a history of 59 recoveries, in 50 of which the stercoral fistulæ had completely closed.

In 1886, during the discussion of gunshot wounds of the intestines, Dr. W. T. Bull³ spoke as follows: "In conclusion, let me make one exception to the rule of treatment I have advocated, namely, to explore bullet wounds. It is in cases where the wound is situated in the posterior part of the abdomen, or in the lateral wall covered by the lower ribs, and there is no evidence of any wound anteriorly."

In the same debate, Dr. Parks, of Chicago, thought that sufficient data had not been offered on which to form a correct diagnosis. He thought the size of the firearm must be taken into consideration, as also the distance, shape of the bullet, its calibre, and that the result of the injury might be affected by the obliquity with which the missile entered the body. He then detailed the remarkable case of a thief who was shot while running away from his pursuers. The bullet was of 44 calibre, and struck him in the back. The next morning he went to the hospital, where it was found the ball had entered the back about four inches from the spinal column, and came out near the umbilicus. He never developed any serious symptoms, and left the hospital on the second day.

Dr. Bryant,⁴ believed laparotomy was a justifiable operation, but that it should not be attempted even in so-called favorable cases, unless the operator could avail himself of many of the recognized means of procedure necessary to combat the shock of the operation, and was sufficiently familiar with its steps to operate with accuracy and despatch.

Dr. Weir said: "Clinically, it is found that every case of such a wound (that is, penetrating,) does not justify laparotomy. When such a case comes under the eye of a surgeon, the collapse which he or she is in may, and too often does, prohibit utterly surgical interference. In only one condition is there an operation justifiable, and that is for the arrest of hæmorrhage which may be the cause of shock."

Before the International Medical Congress in 1887, fæcal extravasation was considered the only clear indication for operation (Hingston). The same year Sir William McCormac wrote: "Some degree of doubt must always exist on account of the necessary obscurity of the symptoms, except in the rare event of prolapse of the injured gut, fæcal extravasation appearing externally; or very free hæmorrhage from the wound." Operation, he thought, was practically useless after twenty-four hours had elapsed, or when general peritonitis and great collapse had set in.

In 1888, Reclus reported the recovery of three cases of perforation of the abdomen. He claimed as the result of experiment that perforation was not necessarily present in cases of penetration, and that therefore laparotomy need not be performed unless the signs were unmistakable. He advised firm compression of the abdomen and large doses of opium; and only when this treatment had failed was laparotomy to be performed.

Two years later, Dr. Lewis A. Stimson showed that the integral statistics of the principal hospitals in New York City to that date were as follows: ⁵ without operation, 28 cases (15 deaths, mortality 65 per cent.);

with operation, 16 cases (13 deaths, mortality 81.2 per cent.). He thought perforation occurred in all cases of penetration save when a small bullet has entered so that its course must lie through the liver, and those in which the ball has traversed the abdominal wall very obliquely. He concludes that in the present state of our knowledge it cannot be said that either interference or non-interference should be the rule of practice, and the surgeon may be guided by his own convictions and feelings, whether they lead him to seek to do as much good, or only as little harm as possible.

In the discussion, Dr. Wyeth thought the question of operation was then involved in as much obscurity as it had been nine years before.

In 1892,⁶ Luhe concluded, from 324 cases, including those of McCormac, Coley and Morton, that laparotomy was indicated in undoubted cases of perforation. He found the mortality in 152 cases of shot wounds was 62.9 per cent.; while for other forms of wounds it was 84 per cent. In those cases in which laparotomy was performed within the first twelve hours, the mortality was 58.2 per cent.; but in those cases in which it was delayed for a longer period, the mortality reached 79.5 per cent.; while the mortality in those cases in which the length of time was unknown was 82.4 per cent.

This shows that delay increases the mortality in operations after these wounds. The rule that immediate laparotomy is necessary, must, of course, have some exceptions, as in military practice where antiseptic precautions and the time necessary for the proper performance of the operation are wanting. He believes the formation of artificial ani will be often necessary, and that transportation should be prohibited during the first few days at least.

In the above papers the difference in the mortality according to the part of the intestine injured, as shown by Assistant-Surgeon Otis, seems to have been overlooked. The following case is cited in support of the correctness of his views:

F. W., colored, age twenty-four, was admitted to hospital on May 31, 1893, about 10.22 A. M. A number of petty robberies had been committed in the place. He was accused by his companions of being the thief. This so preyed on his mind that he tried to commit suicide. With this object he placed the muzzle of a 45-calibre Springfield carbine to the front of his abdomen. The stock he rested on a box about two feet high, then bending forward he pulled the trigger. The bullet entered in the mammary line just a little to the right and immediately below the lower edge of the false ribs on the right side. It made its exit just over the highest point of the innominate bone and about one-fourth of an inch external to the line of the outer border of the axilla. He was seen inside one-fourth of an hour after the accident. A slight amount of pallor existed. He had no hæmorrhage and no blood in his stools. The only sensation he experienced around the wound was one of numbness. There was nothing to indicate that a perforation of the intestines had occurred. It was concluded that if any portion of the intestines had been injured it was the ascending colon, and in view of the favorable results given by Assistant-Surgeon Otis, laparotomy did not seem justifiable. His wounds were dressed aseptically. He was given a liquid diet, and placed on his back. His temperature was sub-febrile in the evening, and thereafter

⁶ Centralblt. für Chir.

as shown in the accompanying chart. On the third day he began to lie with his knees drawn up. This position he explained was to relieve pain which had developed round the wound. At the same time a

slight odor was noticed in changing the dressing. It came from the posterior opening. During the night a quantity of fecal matter came out; and on the following day it amounted to over a pint, and necessitated frequent dressings. For the next ten days it decreased in quantity, and on the twelfth had completely ceased. The photograph was taken a little after this period when both wounds had closed.

As he suffered from pains on exertion, he was kept under treatment until July 20th, when he was discharged. The wounds never reopened; and he has continued to ride horseback and do ordinary work without any inconvenience. His general health remains excellent.

From the above citations, we may safely reach the following conclusions:

(1) That wounds of the large intestine are more liable to spontaneous cure than those of any of the other abdominal viscera.

(2) That antero-posterior perforation of the abdomen, though nearly always followed by perforation of the bowel, is not necessarily so, as shown by the remarkable case of Dr. Parks.

(3) That prolapse of the wounded intestine or fecal extravasation is alone diagnostic of a perforation.

(4) That if operation is indicated, it must be performed as soon as possible, and with the withdrawal and examination of only a small portion of the intestine at a time. The examined portion to be replaced and another section examined in the same way until a thorough search has been completed.

(5) That if the case is not seen for several hours after the accident, drainage by iodoform gauze should be alone attempted, as fibrinous adhesions have been found to occlude the wound and wall off the peritoneal cavity in a few hours.⁷

(6) That in military practice the impossibility of always taking antiseptic precautions, and the urgent necessity for transporting the patient to a base hospital, will often prevent the performance of laparotomy.

The introduction into warfare of the small jacketed bullet, projected with great velocity, will probably not modify the status of abdominal wounds in any material degree. The wounds will be more like a punched-out hole, with little, if any, contusion of the neighboring parts. Fatal hæmorrhage will be more prevalent, and there will be about four times more dead than wounded.⁸ There will also be more men killed and wounded in a given time by the new rifle. The wounds produced, if not immediately fatal, will, however, be more amenable to surgical skill, and much more promptly recovered from.⁹ More penetrating wounds of the abdomen will be liable to spontaneous recovery, while those that come to operation will show an increased percentage of recovery. The general opinion of military surgeons seems to be favorable to the new weapon, so far as experiment and its limited employment in actual warfare enable them to judge.

Reports of Societies.

CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

THIRD TRIENNIAL MEETING, WASHINGTON, D. C.,
MAY 29, 30, 31 AND JUNE 1, 1894.

GENERAL SESSIONS.

(Concluded from No. 23, p. 575.)

FRIDAY AFTERNOON. — JUNE 1ST.

THE business meeting of the Congress was held at 1.30 P. M., the President, ALFRED L. LOOMIS, in the Chair.

DR. NEVINS B. HYDE presented, on behalf of the American Dermatological Association, the following resolution:

Whereas, The American Dermatological Association recognizes the importance of the undoubted existence of leprosy in North America, therefore

Resolved, That the Congress of American Physicians and Surgeons be requested to memorialize the Congress of the United States of America, with the view to the appointment of a commission of five to investigate the prevalence of leprosy in the United States of America and in the countries upon its borders, and to suggest means for the control of the disease.

DR. WILLIAM H. WELCH, of Baltimore, stated that

⁷ Abbe and McGraw.

⁸ Colonel Boonen-Rivera on the War in Chili.

⁹ Thurnwald, in Austria, as the result of experiment, has come to this same conclusion.

a bill had been presented in Congress prohibiting experiments on animals in the District of Columbia, and presented and moved the adoption of the following resolution:

Whereas, The attempts in other countries to regulate by legislation the practice of experimentation upon animals have proven most disastrous to the progress of medical science and art,

Resolved, That the Congress of American Physicians and Surgeons enters its most earnest protest against any legislation tending to interfere with the advancement of medicine by means of experimentation upon animals, conducted by properly-qualified persons.

DR. L. McLANE TIFFANY, of Baltimore, offered the following resolution:

Whereas, The army appropriation bill reduces the number of medical officers in the army by twenty-five, and also reduces the appropriation for the library of the surgeon-general's office from ten thousand dollars to seven thousand dollars,

Resolved, That it is the opinion of this Congress that these proposed reductions are unwise and are contrary to the best interests, not only of the army, but of the medical profession of this country, and of all who depend upon them for skilled professional services, and that we respectfully request our representatives and senators to so amend this bill as to prevent the reductions above referred to.

These three resolutions were adopted.

The question of amendment of the by-law relating to the place of meeting was brought up, and its consideration postponed until the next meeting, when it should be made the special order for the first day's session.

The Congress then proceeded to the scientific work. The first portion of the afternoon was under the direction of the American Laryngological Association, and the subject for consideration was

THE SURGERY OF THE ACCESSORY SINUSES OF THE NOSE.

DR. F. H. BOSWORTH, of New York, read the first paper, which was on

DISEASED CONDITIONS OF THE ETHMOIDAL SINUSES.

Diseases of these sinuses differ from diseases of the other sinuses in their anatomical peculiarities and in their symptoms. In the other sinuses there is one large single cavity; in the ethmoid we have a mass of small cells more or less completely separated from each other. In order to establish a radical cure, it would be necessary to open each one of these cells. This is impossible, and therefore the separating walls must be broken down and a single cavity formed.

Whereas, in the other sinuses the principal symptom is the occurrence of a purulent discharge, ethmoidal disease sets up a train of symptoms more or less neurotic in character, such as headache, intra-orbital pressure, sneezing, asthma, and interference with the action of the brain. Ethmoidal disease is more frequent than is commonly supposed. In the last five years 97 cases of ethmoidal disease had been under his care. There are three varieties of disease of the ethmoid, the extra-cellular myxomatous, intra-cellular myxomatous and purulent ethmoiditis. These varieties are really simply successive stages of one and the same affection. As the disease progresses, the mucous membrane may project into the nasal cavity in the form of small polypi. Another result may be crowding out of the middle turbinated bone, from ex-

tension of the ethmoid cells. The final result is suppuration, and the pus may be discharged through the anterior or through the posterior cells.

Treatment in these conditions should be instituted early, if possible, before the occurrence of suppuration. In acute ethmoiditis, the ordinary measures employed in acute rhinitis are indicated. Of all measures, he regarded the douche as the most valuable. One or two gallons of water, rendered saline and as hot as can be borne, should be passed through the nose twice daily. This is devoid of danger provided the patency of the nostrils is determined beforehand and the water is passed in the narrower nostril so as to obviate any interference with its discharge.

In the chronic stage, surgical treatment is demanded when other measures have failed. The object of the treatment is to relieve the intra-cellular pressure. To remove the projecting portions, the snare answers the purpose best. In operating on the ethmoid cells a small burr attached to a dental engine is the best instrument. The operation usually requires several sittings, and care must be taken on account of the thin bone separating the cavity from the orbit and from the brain. The operation is not especially painful and can be done under the application of cocaine.

Ninety-seven cases had been treated. Of this number three were cases of carcinoma, and one was a case of sarcoma. Excluding these, there were 93 cases. Of the simple inflammatory cases, 15 in number, 9 were cured, 8 improved, and 3 disappeared. There were 29 cases of myxomatous degeneration, of which 12 were cured, 10 improved, and 7 were seen but once or twice. There were 22 cases of myxomatous change with polypi; 9 were cured, 10 improved, and 3 disappeared. There were 27 suppurative cases; 8 were cured, 12 improved, and 7 disappeared. In nearly all of these cases radical measures were employed.

SURGERY OF THE MAXILLARY SINUS.

DR. J. H. BRYAN, of Washington, read a paper on this subject.

Of the surgical affections of the antrum, empyema is the most important, and the principal question that has arisen in regard to its treatment has been as to the method of opening the cavity. The washing out of the cavity through the natural opening has been strongly advised. This is applicable to acute, but not to chronic cases, and the results are uncertain. In the majority of cases, an artificial opening is necessary. If there is a carious tooth present, it should be extracted, and frequently in this way the cavity will be opened. If not, it will be necessary to establish connection by a trocar or small trephine propelled by an engine. The opening should be large, and a metallic drainage-tube introduced. If the anterior wall of the antrum shows signs of weakening, it may be opened at this point. If it is desired to enter the cavity from the nose, it may be done through the inferior meatus by a spear-shaped knife, but it is better to use the trocar or drill. After the cavity has been opened, it should be washed out with mild antiseptic solutions.

Where the case is an obstinate one, the opening should be enlarged so that the cavity may be thoroughly explored with a probe, the little finger or the endoscope. This will often show the presence of spots of ulceration, necrosis, supernumary teeth, etc., as the cause of the trouble.

DR. J. N. MACKENZIE, of Baltimore, also called

attention to the various methods of opening the antrum. Washing out through the natural opening is not applicable to many cases, for it is often difficult to find the opening, and this is so even after death. In order to obviate this difficulty, it has been proposed to remove the inferior turbinated bone; but that does not seem justifiable in the majority of cases. It has also been proposed to make an artificial opening below the natural opening. This is rather difficult to carry out, and the hæmorrhage is sometimes great. The operation of entering the antrum through the canine fossa should only be done in cases of growths, or where the antrum wall is so thin that it is an easy matter to pierce it, and where, if the surgeon does not open the antrum, it will discharge itself. By far the best operation for gaining access to the antrum is that through the mouth, by the extraction of a tooth, whether sound or decayed, or by going through the alveolar process without the extraction of a tooth. The speaker considered this method far superior to any other. This opening furnishes drainage from a dependent point; and when injections are made through the opening, most of the fluid escapes through the nose. The objections that have been urged against the operation are that it involves the loss of a tooth (perhaps sound), that food may enter through the tube, and that there is danger of microbes finding entrance from the mouth. These objections are, however, without weight. There is only one contraindication, and that is the presence of an edentulous alveolar process. In these cases the operation had better be done through the nose.

DR. JOHN O. ROE, of Rochester, read a third paper on this subject.

The treatment of these cases is largely surgical, on account of the fact that they are largely out of reach of ordinary medicinal treatment. Most cases of ozæna are in all probability due to discharge from some of the sinuses of the nose. In cases where the discharge does not rapidly subside under treatment, a free opening should be made. If there is no history of long-standing disease, the treatment should be begun with injections through the natural passage. If the case is recent, the discharge persisting after an acute inflammation, this may bring about a healthy condition. When such treatment cannot be employed, an artificial opening should be made. When the teeth are sound, the opening can be made through the zygomatic region or through the meatus. If the disease does not rapidly subside, it is probable that there are conditions of the cavity which must be dealt with radically. Then a free opening should be made and the diseased conditions removed. The opening should be maintained until we are sure that the disease is entirely cured, when the opening can be safely allowed to close.

The following conclusions were presented:

The old idea of considering drainage and cleanliness as the treatment, regardless of the exciting cause, should be abandoned.

In all cases where the purulent discharge does not cease after a reasonable time, the cavity should be freely laid open, so that the exact pathological condition can be determined.

The opening should be maintained for inspection and treatment until the disease has been cured.

The second portion of the session was under the charge of the American Neurological Association.

DR. JAMES J. PUTNAM, of Boston, read a paper on

THE INFLUENCE OF INFECTIOUS PROCESSES ON THE NERVOUS SYSTEM, PATHOLOGY AND ETIOLOGY.

The relation of nervous diseases to infectious processes may be studied from the point of view of the bacteriologist or that of the neurologist; it is the latter which mainly concerns us now. The nervous system may suffer from local bacterial action, from the effects of toxic products, or from the effects of a lower vitality of the nervous system, making it prone to show signs of constitutional weakness or fall a prey to new causes of disease. The term "infection" is here used for convenience (somewhat loosely) to denote the action of specific virus as well as that of specific organisms.

The infectious diseases which would be admitted by every one to cause nervous affections are tetanus, rabies, syphilis, tuberculosis, diphtheria, lepra, gonorrhœa, typhoid, erysipelas, influenza, mumps, the acute exanthemata, the pyogenic organisms, the diplococcus lanceolatus, malaria, actinomycosis. The nervous affections which follow acute infectious diseases are not always due to that primary infection, but to a secondary infection, or they may be only an indirect result.

The diseases of the nervous system which are suspected (but not fully proved) to be of infectious origin are, especially, beri-beri, poliomyelitis, Landry's disease; certain forms of myositis, neuritis and myelitis; some of the cerebral palsies of children; chorea; disseminated sclerosis and other cerebro-spinal and spinal sclerosis; amputation neuritis; herpes zoster.

Finally, we find a number of affections following in the wake of infectious processes, but hardly to be classed as indicating the action of specific virus. Such are the constitutional neuroses and psychoses, the adynamic cerebral affections, the results of œdema or of arterio-sclerosis; various forms of sclerosis of the spinal cord, to which the nervous system is always prone, and which any one of various poisons will help to bring out; subacute forms of multiple neuritis of the ordinary type, such as arise from manifold causes.

A disease may be suspected to be of infectious origin when bacteria are found in the tissues; when the outbreaks occur in epidemics or are related to seasons or locality; when it exhibits vascular and histological changes characteristic of the infection, or specific toxicity of the blood and urine; or it has become much less frequent since the introduction of antiseptics. The discovery of bacteria is by no means conclusive, since they are often only incidentally present. We should suspect a disease of not standing in a very close relation to infection if it was of a kind developing under other influences; and it is therefore important to study what are the morbid conditions which occur most easily as a consequence of various general strains and as a result of heredity. The French school has done much in this direction. The arguments are strong in favor of the infectious origin of the different forms of acute (often hæmorrhagic) myeloneuritis or polymyositis, including beri-beri (the epidemic disease of Northern fishermen), Landry's disease, poliomyelitis. We can at least say that they are due to some poison acting powerfully for short periods and in the manner characteristic of bacterial toxins. Bacteria have been found in Landry's disease, but are not yet accepted as specific. Chorea is probably of infectious origin (Pianese, Dana, Berkley). Bacteria

have been found which may or may not be specific. Myelitis (acute, focal or transverse,) may be produced experimentally by injection of cultures. It also may follow gonorrhoea, and may occur in a manner suggestive of other infectious causes. Amputation neuritis is said to have become less common since the introduction of better methods of asepsis. There is little to be said for the infectious origin of zoster.

Acute multiple neuritis may follow almost any one of the infectious processes, but it is difficult to say just what relation it bears to them. The lesions observed have more of the vascular and interstitial character than is ordinarily met with in neuritis of inorganic origin, but are doubtless often due to the products of metabolism. Sometimes, as in diphtheria of rapidly fatal course, no obvious lesions are produced, but modern research is continually widening our resource in this direction; witness the recent observations of Golgi in rabies, and the investigations of Nischl and others into the pathology of the nerve cell. The meningitis which follows the exanthemata is probably due to secondary infection. It cannot, however, be affirmed that the absence of bacteria indicates the absence of specific local action in diphtheria and other affections; the virus seems to be almost the equivalent of the organism in its power of exciting local reaction. The meningitis which complicates typhoid, pneumonia, and perhaps influenza, is generally due to the primary infection, at least in part. Epidemic cerebro spinal meningitis and sporadic forms are generally due to the diplococcus lanceolatus, the same germ which causes pneumonia; sometimes also to other organisms. Recent research has accentuated the importance of purulent and even simple catarrhal affections of the naso-pharynx and the ear as starting-points for meningeal affections. The specific organisms liable under favorable conditions to cause meningitis are often present in even the healthy pharynx.

Sometimes the infective agent seems to make its way in from the intestinal tract.

If we except the cerebro-spinal membranes, which are a great breeding-place for many bacteria, we may say that the instances of local bacterial action upon the nervous system are few, while, on the other hand, the nervous system is especially prone to suffer from toxic agents circulating in the blood. These poisons are sometimes separable into several definite constituents, which vary as regards their volatility, their solubility in alcohol and their physiological action. Several of them have a strong tendency to attack the vaso-motor system in various ways; and the disturbance of the circulation thus produced is liable to prevent the normal vascular dilatation which is so necessary for the protection of the body against the invasion of pathogenic organisms. These poisons affect the nervous system in various characteristic ways, though it is not improbable that they are capable of acting as universal neurotic poisons. In tetanus (Brunner) the irritability of the spinal cord is heightened as in strychnia poison; in diphtheria, the cardiac centres are sometimes strongly involved, though gross lesions may be absent; in influenza the tendency of the poison is towards the brain more than in the case of some of the analogous diseases. Besides the psychoses which are common, acute hæmorrhagic encephalitis occurs.

As regards chronic poisoning or its results, we find disseminated sclerosis after various acute infectious diseases, and especially after malaria; but it is not

probable that they are due to the action of the specific virus of this antecedent malady.

The causes which contribute to increase the liability of the nervous system to suffer from the effects of infectious disease may be divided into two classes:

- (1) Those which increase the liability to invasion of the body by pathogenic organisms;
- (2) Those which lower the resistance of the nervous system.

Of the latter class are hereditary weaknesses in special directions, the presence of other poisons in the nervous system, the effects of trauma, a poorly acting vaso-motor system.

Debility of the nervous system may contribute to increase the liability of the body to invasion by impairing the vitality of the tissues which should resist the germs of disease, besides impairing the efficiency of the vaso-motor reaction.

The most important lines of research for the future are in the direction of classifying the special liabilities on the part of the nervous system to disease independently of infectious causes, the refinement of our methods of histological research, the more widespread and thorough study of bacteriology and of the means of determining the toxic condition of the blood and urine.

RELATION OF INFECTIOUS PROCESSES TO MENTAL DISEASE,

by CHARLES K. MILLS, M.D., of Philadelphia.

Nearly a century ago, Rush declared that certain causes as gout, dropsy, consumption, pregnancy, and fevers of all kinds produced madness by acting on the brain in common with the whole body; and before the time of Rush and since, this subject has claimed the attention of the medical profession. It is, indeed, only one aspect of the old humoral doctrine, to which we now recur with the important aid furnished by experimental research.

Among the questions to be considered are, Whether the mental disorders of well-known forms of infectious disease are toxæmic, or are due to anæmia, exhaustion or other causes, and whether particular types of insanity are due to the action of special micro-organisms? In endeavoring to answer these and similar questions, we are naturally led to consider inferences and conclusions drawn from, first, clinical and clinico-pathological observations; second, from analogies with affections of the nervous system not psychoses, but which are known or believed to be of microbic origin; and third, from the consideration of the combined clinical, pathological and bacterial observations and investigations.

Under clinical and clinico-pathological observations are included the so-called febrile and post-febrile insanities. Regis and Chevalier-Lavaure, in a report at the Congress of French Alienists in 1893, and Hurd, in a paper published in 1892, have furnished valuable summaries of the literature of infectious processes in their relations to mental disorders, and have considered the subject from various points of view. The former distinguished mental disorders due, first, to infectious diseases; second, to visceral disturbances; and, third, those associated with diathetic maladies.

While not denying the origin of mental manifestations and even special types of insanity from other causes, such as traumatism, anæmia, exhaustion, and emotional shock, these are sometimes due to the action of infectious intoxication and probably to specific micro-organisms, although the last cannot be regarded as

absolutely proved. The question of febrile delirium and febrile and post-febrile insanity has been especially considered by numerous observers. A special type of confusional insanity has been suggested as following infectious and diathetic disorders. Hurd, Korsakoff and Tuke and Woodhead favor the idea that this type of insanity is essentially a toxæmia, and due to a special poison such as is developed in multiple neuritis, influenza and other infectious disorders. Numerous cases have been reported by Chomel, Esquirol, Simon, Hurd, Chaslin, Lloyd and Tull, Frantzel and Strube, and Liebermeister. Much negative evidence in favor of the infectious origin of acute mania or acute delirium has been furnished by clinico-pathological observations. In the case of Lloyd and Tull (one of severe acute delirium or mania), the autopsy revealed nothing positive, unless it was an uncertain incipient meningitis.

Several similar cases have fallen under the author's observation. In one case of acute delirious mania (with hyperæsthesia, active contractions and petechial eruption), the symptoms were highly suggestive of cerebro-spinal meningitis, but the autopsy revealed nothing and the case was apparently one of toxæmia associated with anæmia. Many other such cases might be cited.

An argument in favor of the view that the mental disorders of the infectious diseases are due to toxæmia rather than to anæmia, exhaustion or other causes, is furnished by the well-known fact, that such diseases are sometimes ushered in by violent mental manifestations, or that such manifestations are the chief features of the disease which pursues a course largely afebrile.

In considering the analogies with mental affections, not psychoses or insanities, but which are known or believed to be of microbic origin, it is only necessary to briefly refer to such diseases as multiple neuritis, some forms of myelitis and chorea. The mental disorders of multiple neuritis have now been frequently recorded; as also have chronic insanities with mental manifestations equal in violence to the motor disorder. The teachings of the recent epidemic of influenza are important in this connection. Of great interest are the views of Marie, with reference to the poliomyelitis origin of the lesions of the white medullary fasciculi in pellagra. Pellagra is a disease doubtless of infectious origin, with marked nervous and mental manifestations associated with the lesions of the skin, and in which pathological and microscopical investigations show combined lesions in the lateral and posterior regions of the spinal cord. Comparing lesions of this affection with those of general paralysis, and the forms of sclerosis, it is fair to argue in favor of the possibly infectious origin of all.

As yet, literature has afforded but few combined bacteriological, clinical and pathological investigations. The most valuable contribution thus far is that of Rasori, on the etiology and pathogenesis of acute delirium. Rasori describes in detail a case of acute delirium, with autopsy, and the results of a careful bacteriological examination. The autopsy was conducted with the strictest bacteriological precautions. Two inoculations with subdural fluid led to the development of the same micro-organism, a small bacillus with rounded ends three times as long as its width. Rasori made numerous experiments, and found that the micro-organism grew well in different culture media. He made a series of four inoculation experiments upon rabbits. The experiments demonstrated that the ba-

cillus obtained from the subdural fluid of the patient grew and multiplied in the body of a rabbit, and produced a toxic substance which destroyed the animal, with symptoms of septicæmia, at a period varying from one and a half to six days.

In 1893, in consultation with C. S. Potts, of Philadelphia, the author saw a case of acute delirious mania — also taking part in the autopsy on the case — a report of which has since been made by Dr. Potts. Cultures were made from the cerebro-spinal fluid by Dr. D. Braden Kyle, and demonstrated the presence of the so-called streptococcus lanceolatus, or pneumococcus of Fränkel and Weichselbaum, and also the staphylococcus pyogenes aureus and albus. Microscopical examination of the cortex showed peri-vascular exudation and leucocytes in the lymph sheaths and periganglionic spaces. Dr. Potts, in reporting the case, suggested that as the germs isolated were those usually found in meningitis, the lack of microscopic findings was probably due to the fact that the toxæmia was so violent as to cause the death of the patient before naked-eye appearances had time to develop.

Through the kindness of Dr. N. P. Ball, of Philadelphia, the author was able to present the report of a case of acute delirium, with autopsy and the results of a careful bacteriological examination. The patient was suddenly attacked with delirium, having previously been to all intents and purposes in the best of health. He had marked delusions with hallucinations, and believed that people were coming to attack him. He committed suicide. The autopsy revealed under the dura several fresh patches of exudation; the pia was glassy, and covered with two or three spots of a greenish-white exudate; the ventricles did not contain the usual amount of serum. Three small round cysts filled with a milkish-colored gelatinous fluid were found in the choroid plexus on each side. Cultures were obtained from the ventricle serum and the contents of the cysts. The following is an extract from Dr. Ball's bacteriological report: "In both cases in two days a fine growth occurred along the needle tracts in a gelatine agar tube; a sparse, whitish growth on the surface of the tube not liquefying. The germ obtained was a very small bacterium arranged in twos and threes, resembling micrococci very much, and plainly larger in one diameter than the other."

Dr. James R. Hunt, of Philadelphia, had furnished the author with the notes of another unpublished case. The patient was under the care of Dr. John Ashhurst, Jr., in the surgical wards of the University Hospital. He was a German laborer, twenty-six years of age, who presented a history of obscure renal disease extending over a period of six years. A distinct resistance was felt in the region of the right kidney, which was quite tender on pressure. The urine contained numerous pus cells, but no blood and no crystals. An exploratory operation was performed. The man was irrational immediately after the operation; and this state gradually merged into one of moderate delirium, which on the seventh day actually amounted to mania; this lasting until death, which occurred ten days after the operation. The autopsy was made by Dr. H. W. Cattell. The right kidney lay in a bed of foul-smelling, somewhat greenish pus resembling tubercular sputum. On section, the renal substance was found infiltrated with pus, with great destruction of its upper portion. Examination of the brain and meninges was negative, with the exception of a slight haziness of the

pia and some turbidity of the fluid in the lateral ventricles. Cultures made from the meninges were negative, but from the fluid found in the lateral ventricles a pure culture of the bacillus pyocyaneus was obtained. Cultures from the pus in and about the kidney contained yeast and pus organisms, but not the bacillus or bluish-green pus obtained from the ventricular fluid.

Interesting studies showing the toxic and bactericide action of the blood of the insane have been made by D'Abundo, and have yielded interesting results. The toxæmias of pregnancy and the puerperal state sometimes result in a mental disorder, and are important in the discussion of this subject. A certain number of the cases point strongly to an acute intoxication with the products of bacteria. In one of a series of cases reported by Davis, a condition of marked toxæmia (with restlessness, melancholia and other grave symptoms) was noted, but in which examination of the urine failed to reveal casts, albumin or marked deficiency in the urea. Tuke and Woodhead believe that in puerperal insanity a considerable proportion of the cases are due to toxic influences without reference primarily to childbirth. Olshausen has observed psychoses eleven times following eclampsia in two hundred cases. He suggests classifying these cases as psychoses directly due to febrile puerperal processes, idiopathic psychoses without bodily or febrile disease, intoxication psychoses following eclampsia or, exceptionally, uræmia without eclampsia.

While, so far as the author has been able to learn, no satisfactory bacteriological examination has been made in a case of puerperal mania, Kaltenbach, or rather Gerdes under the direction of Kaltenbach, made an exact and exhaustive bacteriological examination of the organs of a woman who died of puerperal convulsions; and the results obtained in this investigation would have equal significance in the explanation of fatal puerperal mania. Cultures were made from the lungs, kidneys, liver and the aortic blood; and in all cases a growth developed which consisted entirely of a pure culture of a very short, thick bacillus. Its culture showed certain characteristic peculiarities. In a later article Gerdes declared that the eclampsia bacillus is the sole cause of puerperal eclampsia, and is found in no other disease, and that there can be no eclampsia without its presence. The infection proceeds from the uterus, probably from an endometritis existing prior to conception. The bacteria of puerperal infection as summarized by Williams, are, however, the streptococcus pyogenes, the staphylococcus albus and aureus, the gonococcus and the colon bacillus. He holds that it is also quite probable that some of the putrefactive organisms play an important part in what Matthews Duncan has designated as sapræmia.

Conclusions may be drawn as follows:

(1) Specific infection must be included among the causes of the mental symptoms, in diseases which precede, accompany or follow febrile and other infectious disorders.

(2) Much negative evidence can be adduced to show that acute delirium or acute mania is due to toxæmia. Such evidence is afforded by autopsies which reveal neither gross or histological lesions; in these cases the toxæmia probably overwhelms the patient before the production of meningitis or other diseases with recognizable structural lesions.

(3) Analogies with nervous affections which are known or believed to be of microbic origin — such dis-

eases as multiple neuritis, myelitis and chorea — favor the view that insanities with similar or related phenomena and lesions are also microbic in origin.

(4) The evidence afforded by careful bacteriological investigation of cases of acute insanity is thus far meagre and shows that various micro-organisms may induce the same or similar types of mental disease.

(5) The mental disorders of pregnancy and the puerperal state are in a considerable proportion of the cases toxæmic without reference primarily to childbirth; but it cannot be regarded as proved that a bacillus of either eclampsia or puerperal mania is the sole cause of these affections.

THE THERAPEUTICS OF INFECTIOUS PROCESSES OF THE NERVOUS SYSTEM,

by FRANCIS X. DERCUM, M.D., of Philadelphia.

The consideration of the treatment of infectious nervous processes involves not only the treatment after infection, but also its prevention. From much that we know, we have reason to believe that the occurrence of infection is markedly influenced by the nervous system. The ability to resist infection depends largely upon the maintenance of normal nervous tone. We have also learned that the nerve cells undergo certain changes in the course of their functional activity, and these changes can only be interpreted as those of fatigue. The first problem is the prevention of undue waste of nervous substance from undue or excessive fatigue. The necessity for a proper proportion of sleep and exercise, and suitable food, must be borne in mind as an important element in prophylaxis.

Are there any means of special prophylaxis against this or that infectious disease? Here the answer is uncertain. The preventive inoculation of Pasteur, Behring, Tizzoni and Catanni suggest themselves, but at the same time doubts as to the advisability and the applicability of the methods arise.

Again, is there anything that can be done in the various infectious fevers, in general pyæmia, to prevent nervous infection? Where the nervous system is threatened by the existence in other structures of foci of infection, the indications to remove these foci of infection is clear.

In regard to treatment, the general indication is to arrest or limit the infectious process, and to bring about elimination of the morbid products. To meet the first indication is not as yet possible; but the field of chemistry and of the biological laboratory may in the future yield great discoveries.

The attempts to combat infectious microbes by means of the toxins which they produce was then considered; but with the possible exception of tuberculosis and lepra, the symptoms produced by infectious micro-organisms appear to be due, not so much to the germ, as to these very toxins.

With regard to tuberculosis of the nervous system, the use of the lymph of Koch has been shown to be not only useless but dangerous.

In the treatment of leprosy by the use of lymph, the failure appears to have been almost equally marked.

With regard to hydrophobia, the literature was reviewed at length, and the conclusion reached that it was vain to deny the truth of Pasteur's experimental researches on animals, while the evidence as regards human beings in specific instances is strong and convincing.

In reference to tetanus, the condition is still more

interesting. A full review of the literature of the subject was given by the author, who had himself collected reports of 84 cases treated either by the powder of Tizzoni or by the serum. Of these, 20 cases were successful, but in some of these cases other measures such as amputation or early active treatment of the wound were employed. There is no contra-indication to the employment of these antitoxines, as it appears to be in no way injurious.

The other means at our disposal for combating the infectious nervous processes resolve themselves into general remedies, drugs and surgical procedures. Cold has been applied with varying success. It is not improbable that baths of suitable temperature might prove of service in the treatment of infectious nervous diseases. Whether or not by this means the elimination of toxins would be favored, is a matter that at present can only be conjectured.

With regard to drugs, we meet little that is encouraging or gratifying. In leprosy, especially, much has been claimed for gurjon, oil of chaulmoogra. In chorea, which is probably infectious, Dr. H. C. Wood has advanced quinine as of considerable value. Antipyrine also has its advocates.

Surgical procedures enable us occasionally to accomplish definite and often brilliant results. This is especially true with regard to the evacuation of pus in positions formerly considered inaccessible, as in brain abscess.

In conclusion, the author offered a suggestion in regard to the treatment of tetanus which he thought might prove of value. It has been observed that the tetanus bacillus while growing in thymus infusion did not develop spores, and that animals injected with such cultures were highly immune to the cultures of tetanus grown in other media. If thymus-juice possesses such remarkable properties, it should be tested with a view to its possible therapeutic effect. Its administration, in a case of tetanus, beneath the skin, could certainly do no harm, and might do good; and it might also be administered by the mouth. If successful, it would prove far more valuable than the anti-toxine, because so readily procured.

This completed the scientific work of the Congress.

The President DR. ALFRED L. LOOMIS, in adjourning the Congress, congratulated the members on the fact that registration had been larger at this than at any other of the previous meetings. The attendance at the sessions of the various constituent associations had also been larger, and the work of a high degree of merit. There had been a united feeling and action among the different societies in support of the Congress, and the different associations had become more closely united than ever before. He considered the Congress to be one of the most important medical bodies in this country, as it brings together skilled workers in all the departments of medicine and surgery, and brings about unity of thought and action among medical men. If there is one body more than another in this country that is to raise our profession from the position which it has occupied so long, it is such a body as has been assembled here for the last four days.

COST OF THE SMALL-POX EPIDEMIC IN BOSTON.
—The recent epidemic of small-pox cost the City of Boston nearly \$25,000, of which \$19,000 was spent for providing free vaccination.

AMERICAN SURGICAL ASSOCIATION.

ANNUAL MEETING, WASHINGTON, D. C., MAY 29, 30, 31 AND JUNE 1, 1894.

(Concluded from No. 23, p. 587.)

SECOND DAY. — WEDNESDAY.

THE first paper read was that of DR. JOHN S. BILLINGS, of Washington, on

METHODS OF TEACHING SURGERY.¹

This was followed by a paper sent by JOHN CHIENE, M.D., of Edinburgh, on

THE TEACHING OF SURGERY.

In discussing this subject one must begin with a warning. The personal equation relating to himself and the traditional equation relating to his school must be allowed for and discounted. The teaching of surgery resolves itself into two heads:

(1) Systematic consideration of general principles illustrated by clinical examples.

(2) A clinical (bedside) opportunity given to observe, to use, and to educate all the faculties, physical and psychical.

Under either head the teacher must be a learner, the student must be a teacher. The teacher has constantly to warn the student against a blind belief, and at the same time he has to speak most decidedly in giving his opinion. The practice of surgery to be successful must be dogmatic.

It has been objected to systematic lectures, that now that we have books there is no need of a hundred lectures on any subject. Those who hold these views can never have known the stimulus of speech; can never have felt the electrical impulses passing between hearer and speaker.

The method of teaching surgery in Edinburgh was then described.

In conclusion, the writer wished to add a word with reference to the teacher of surgery. He believed in a fallow time, in a time of rest from mental activity. The best rest is change of scene. He suggested the advantages that would accrue from an interchange of chairs in the great English-speaking educational centres. In this way once in seven years a teacher would for a session leave his alma mater and speak to the students of another school. Or the fallow might take another aspect; give a teacher a session off every seven years, and let him do in it what seems to him good.

The discussion of these papers was participated in by Dr. J. Collins Warren, of Boston; Dr. W. W. Keen, of Philadelphia; Dr. Hunter McGuire, of Richmond, Va.; Dr. Chas. B. Nancrede, Ann Arbor, Mich.; Dr. P. S. Conner, Cincinnati, Ohio; Dr. W. S. Forbes, Philadelphia, Penn.; Dr. Robert F. Weir, New York, N. Y.; Dr. T. F. Prewitt, St. Louis, Mo.; Dr. John E. Owens, of Chicago, Ill.

THE SURGERY OF THE KIDNEY,

by L. McLANE TIFFANY, M.D., of Baltimore, Md.

The subject was such a large one that the author considered only those points which offers opportunity for difference of opinion. In the human body bilateral organs are more than sufficient for the carrying on of life; not only may one such organ be removed without impairing existence, but even the remaining organ may be more or less damaged and yet life be carried

¹ See Journal, No. 22, page 535.

on. Any paper on surgery of the kidney at the present day must take into consideration the influence of the disease of the kidney on various operations of general surgery. The influence of anæsthesia on the healthy kidney should be considered. In 150 cases of operation where healthy kidneys were present, albumin was found only in two per cent. of the cases after operation. Every case of railway accident, and some other cases where the patient had been exposed for a certain time, showed albuminous urine on admission to the hospital. In these cases operation has not been deferred on this account. Cases of advanced diabetes have not been operated on. In cases with healthy kidneys the amount of urine passed in the twenty-four hours following operation is diminished in quantity, the specific gravity usually being a little higher.

As to wounds of the kidney, there was no good reason why the kidney should be separated from the rest of the body and require different surgical treatment. A kidney wound should be exposed, sutured, drained, tamponed with gauze, or a piece of it excised in injury beyond repair, or drained, as the case may be, and not the whole kidney sacrificed.

Nephritis and pyelo-nephritis, so-called surgical kidney, is generally met with by the surgeon—a process (organic) resulting from extension upwards of inflammation from the urethra or bladder due to the presence of bacteria. The bacteriology of the trouble in question is yet to be written. In so-called pyelo-nephritis beginning in the kidney, the most frequent cause is stone. The surgeon has especially to deal with the ascending inflammation from the urinary channel below, more often obstructive. The diagnosis is usually not difficult when the disease is advanced. In the early stages the difficulty of diagnosis is great, especially is it difficult to recognize whether the trouble affects one kidney or both. Here it is that the cystoscope offers great opportunity. A moderate amount of urine, with a low specific gravity, and an habitual low temperature independent of the conditions of the pulse are danger signals more important than any others. In the recognition of the kidney affected, we have to rely on pain, pressure and the cystoscope. The treatment before operation consists in exciting the kidneys to secrete by means of infusion of digitalis, acetate of potassium and infusion of buchu. Acid urine and pus suggest pyelo-nephritis very strongly. It is the author's habit not to operate until the patient's kidneys are acting well. After operation, strychnine hypodermically is a useful addition to the previous treatment. The hot-air bath has proven unsatisfactory in chronic cases. In acute cases it is beneficial. Free purgation is of advantage.

Where an operation on the bladder is called for, and there is evidence of disease of one kidney or decided pain in one kidney suggesting disease, that kidney should be operated on at the same time as the bladder. Twice the speaker had done lithotomy for stone in the bladder, the lithotomy being done and the kidney opened at one and the same sitting. All went well. In another stone case, within two weeks, acute suppurative inflammation took place and was followed by death. In a second case there was a similar occurrence.

THE SURGICAL TREATMENT OF SURGICAL KIDNEY,

by ROBERT F. WEIR, M.D., of New York.

Suppurative pyelo-nephritis, suppurative interstitial nephritis and surgical kidney are the ordinary names

given to a disease which originating, as a rule, in the bladder, generally affects both kidneys. In this affection the kidneys are congested and studded with foci of pus. Dr. Delafield states, that so far as he knows all cases die. While this may be the general result, a case reported by the speaker shows that some modification of this prognosis must be made.

H. W., age twenty-five years, was admitted to the surgical wards of the New York Hospital on April 2, 1894. Four years previously he had scarlet fever followed by nephritis. About one year ago he had a mild attack of urethritis. Three months ago he had a severe attack of urethritis which invaded the bladder; gonococci were present in the discharge. This gradually subsided under treatment. Twelve days prior to admission to the hospital he had, without assignable cause, a chill followed by fever. The following day there was pain in the loins, with subsidence of the fever, but the next day the temperature reached 103° F. There was no increase in frequency of urination. The lumbar tendency gradually increased. He was admitted to the medical wards of the New York Hospital March 28th. During the next seven days he had four chills, the temperature ranging between 103° and 105°.

The patient was seen by Dr. Weir April 8d. His condition was a most serious one. The urine contained pus, and was fifty or sixty ounces in amount. There was pain in the right lumbar region, with tenderness on pressure. It was thought that some enlargement of the right kidney could be made out. The impression of the speaker was that there was an abscess of the kidney, or possibly several such of considerable size. He did not think that it was the "surgical kidney," on account of its one-sided character. On April 4th the kidney was exposed in the usual manner. Puncture in two or three places gave no evidence of pus. An incision was made into the kidney, disclosing numerous miliary abscesses, and showing that we had to do with ordinary surgical kidney. It was then decided to extirpate the infected organ. Immediately after the operation the temperature fell from 105° to 99°. The patient made an uninterrupted and rapid recovery, being discharged on April 20th.

It is difficult to say how often the affection is limited to one kidney, but this may not be infrequent. Even where both organs are involved, it may be that something may be done for the relief of tension and the egress of pus by means of free incision made into the kidney substance.

With the happy experience of this case, the reader considered it hereafter justifiable, if the patient's general condition would warrant it, in a case of acute septic invasion of the kidneys, to make on one or both sides an exploratory incision, not only in the hope of relieving the acute interstitial invasion, but also of perhaps encountering a larger and well-defined focus of pus—which pathological condition cannot always be readily discriminated from the more dangerous lesions of the veritable surgical kidney. Should the symptoms point, as in the case narrated, to one kidney only, or should a double exploratory incision show the same result, a nephrectomy may with some hope be resorted to.

SURGERY OF THE URETERS,

by CHRISTIAN FENGER, M.D., of Chicago.

Accidental wounds and subcutaneous ruptures of the

ureter have not as yet been objects of direct surgical procedure upon the ureter at the seat of lesion.

Catheterization of the ureters from the bladder for the purpose of diagnosis has given valuable information. The procedure is reasonably practicable in the female. In man, catheterization is practicable only through epicystotomy.

Catheterization of the ureter from the bladder as a curative measure for the evacuation of hydro- or pyonephrosis, has occasionally been performed. This is more difficult and uncertain than nephrotomy and the attempt to find and remedy the stenosis of the ureter from the pelvis of the kidney.

Dilatation of strictures of the female ureter by elastic bougies has been tried from the bladder with temporary success, and from the pelvis of the kidney successfully.

Permanent catheterization of the ureter from the bladder, a fistula or an implanted ureter is often tolerated only for a limited time, and must be employed with caution.

Uretero-lithotomy is a safe operation by the extra-peritoneal method.

Intra-peritoneal ureterostomy should be done only when access outside of the peritoneal cavity is impossible, and should be completed by careful suturing, covering with omental or peritoneal flap, and drainage.

Opening of the peritoneal cavity to locate the seat of stone may occasionally be necessary; but when the diagnosis is once made, ureterostomy should be done by the extra-peritoneal method.

In valve formation or stricture of ureter causing pyo- or hydro-nephrosis or a permanent renal fistula, nephrotomy should be followed by exploration of the ureter. This is to be done by a long, flexible, silver probe or an elastic bougie. The size of a bougie that will pass a healthy ureter is from No. 9 to No. 10, French scale.

Operation for valve formation should be done through the wound in the pelvis. A stricture in the ureter, if not extensive, can be treated by a plastic operation. Resection of the upper end of the ureter and implantation of the distal end into the pelvis has been performed with success.

Utero-uterine fistulas can be treated satisfactorily by plastic closure of the vagina, or nephrectomy. Implantation of the ureter into the bladder is, under favorable circumstances, the operation of the future for this condition.

Uretero-vaginal fistulas should be treated by vaginal plastic operation for displacement of the distal end of the ureter into the bladder.

Complete transverse wounds in the continuity of the ureter should be treated by uretero-ureterostomy after the method of lateral implantation if possible. Complete transverse wounds of the upper end of the ureter should be treated by implantation of the ureter into the pelvis of the kidney. Complete transverse wound of the ureter near the bladder should be treated by implantation into the bladder.

Loss of substance of the ureter too extensive to permit of uretero-ureterostomy, or too high up to permit of implantation into the bladder, may be treated by implantation on the skin or into the bowel. Implantation into the bowel is objectionable. Implantation on the skin in the lumbar region may have to be followed by secondary nephrectomy, which, however, is much less dangerous than the primary operation.

THIRD DAY. — THURSDAY.

EXECUTIVE SESSION.

The following officers were elected: President, Dr. F. S. Dennis, of New York; Vice-Presidents, Drs. J. R. Weist, of Richmond, Ind., and J. B. Roberts, of Philadelphia. Secretary, Dr. M. H. Richardson, of Boston. Treasurer, Dr. N. P. Dandridge, of Cincinnati, O. Recorder, Dr. DeForest Willard, of Philadelphia. Member of Council, Dr. T. F. Prewitt of St. Louis, Mo.

The next meeting is to be held in New York City.

Dr. Dudley P. Allen, of Cleveland, O., was elected to membership.

The following were elected to honorary membership: Sir Spencer Wells, F.R.C.S., London; Dr. William MacEwen, Glasgow; Dr. M. H. E. W. Schede, Hamburg; Prof. Ernst V. Bergman, Berlin; Prof. Karl Thiersch, Leipzig; Prof. Theodor Kocher, Bern; Prof. Jules E. Péan, Paris.

REGULAR SESSION.

DISCUSSION ON RENAL AND URETERAL SURGERY.

(Postponed from Wednesday.)

DR. M. H. RICHARDSON, of Boston, emphasized the importance of examination of the urine prior to all operations. In regard to the method of performing nephrectomy, he dwelt upon the abdominal method, the incision being made in front laterally. This enabled the operator to control bleeding which was the chief source of danger in the operation. In this method the surgeon was able to determine the presence or absence of the other kidney. He believed that by this method the mortality of nephrectomy would be greatly reduced by so providing for hemorrhage that it could not be an element in the mortality.

DR. H. H. MUDD, of St. Louis, Mo., agreed with Dr. Tiffany that in traumatic lesions of the kidney (even gunshot and stab wound), it is not always necessary to do nephrectomy. He had seen such cases recover. He had also met with a number of cases of extensive laceration of the kidney from contusion, in which there was no external evidence of such injury. Many of these cases recovered without operation. When operation was needed, he believed that partial nephrectomy was justifiable. If necessary, a secondary operation could be done as a primary operation; the removal of kidneys so injured was apt to be disastrous.

In pyelo-nephritis and renal lithotomy the first operation should be tentative, consisting of incision and evacuation, the kidney being allowed to remain; a secondary operation being performed if necessary.

He did not favor the abdominal incision for the removal of the kidney, on account of the risk of infecting the abdominal cavity in suppurative conditions of the kidney, and because the lumbar incision was usually sufficient, and if necessary it could be extended and the abdomen opened.

DR. T. F. PREWITT, of St. Louis, called attention to several cases of renal stone, laceration, etc., coming under his observation. One of these cases was that of a man who had passed scales of stone by the urethra, and in whom operation showed a stone in the pelvis of the kidney, with several small detached particles. He was unable to offer an explanation of this separation. With regard to diagnosis, he held that a large amount

of pus with a small amount of mucus in the urine indicated that the trouble was in the kidney rather than in the bladder.

DR. W. S. FORBES, of Philadelphia, called attention to the tolerance of the kidney to the presence of stone. He related a case where autopsy revealed the presence of a stone in the pelvis of the kidney, and in which during life there were no indications of stone. The character of the stone was peculiar, in that it was what is known as indigo stone.

DR. CHAS. B. NANCREDÉ, of Ann Arbor, Mich., had used the abdominal method of nephrectomy in four cases, but he did not favor it in suppurative conditions of the kidney. In order to avoid hæmorrhage he had used an elastic ligature, gradually slipping it down and removing the kidney piecemeal until the pedicle was reached. In the treatment of suppression of urine that may follow these operations he recommended the use of nitro-glycerine, which he had used with advantage.

DR. JOHN B. DEEVER, of Philadelphia, added his testimony in favor of the anterior incision in nephrectomy. He felt certain that with proper precautions the danger of infection of the peritoneal cavity could be avoided.

DR. STEPHEN H. WEEKS, of Portland, Me., reported the case of a man who developed an abscess in the groin after having had symptoms of renal colic some months before. On opening this abscess, pus was discharged, and subsequently a small calculus was passed. No urine was discharged through the abscess at any time. The sinus has since almost healed.

DR. WILLIAM H. CARMALT, of New Haven, Conn., reported the case of a woman on whom it was thought that nephrectomy might be required. On preliminary examination through an abdominal incision, only one kidney could be discovered. The patient died three years later, and autopsy showed that the second kidney was located in the pelvis.

THE TREATMENT OF INOPERABLE MALIGNANT TUMORS BY THE TOXINES OF ERYSIPELAS AND PRODIGIOSUS,

by DR. WILLIAM B. COLEY, of New York.

Dr. Coley began the treatment of inoperable sarcoma by repeated injections of living cultures of erysipelas streptococci, in May, 1891, and continued this method of treatment in ten cases: (six sarcoma and four carcinoma) a report of which was published in the *American Journal of Medical Sciences*, May, 1893.

In but four of these ten cases was he able to produce erysipelas; yet the marked improvement which in several cases followed the repeated injections where no erysipelas was produced, led him to believe that the greater portion, if not all, of the curative action of the erysipelas, was due to the toxic products rather than to the germ itself.

The first experiments with the toxines were made in 1892, with bouillon cultures prepared by heating to 100° C. The effect on the tumors was slightly less than when living cultures were used.

Early in 1893, he began to use bouillon cultures filtered through porcelain, without having been subjected to heat. The toxines of bacillus prodigiosus, prepared in the same way, were used in conjunction with the toxines of erysipelas. This was done with the idea of intensifying the action of the erysipelas upon sarcoma, it having been proven by bacteriologists that the virulence of the erysipelas germ could be

increased by combining it with the bacillus prodigiosus.

The action of the combined toxines has been proven, to the writer's satisfaction, very much more effective than that of the erysipelas toxines alone, and to this combination he attributes the successful results.

The toxines, to be of value, must come from very virulent cultures, and must be freshly prepared. All of the successful cases were treated by toxines derived from cultures from a fatal case of erysipelas.

Twenty-five cases of sarcoma, eight cases of carcinoma, and two cases of sarcoma or carcinoma, were treated with the combined toxines. Including one case treated by the injections of fluid living cultures, there were five cases in which it was reasonable to hope for permanent cure.

The first, sarcoma of the neck and tonsil, twice recurrent. Has gone nearly three years without treatment.

A second, sarcoma of the back and groin, is perfectly well and free from recurrence fourteen months after cessation of treatment.

A third, sarcoma of the abdomen and pelvis, is in perfect health one year after leaving the hospital, and the very small portion of the tumor which had not been wholly absorbed has remained dormant.

A fourth, sarcoma of the abdominal wall, which had entirely disappeared under two and a half months' treatment with the toxines, is perfectly well and without recurrence three months after treatment was discontinued.

A fifth, sarcoma of iliac fossa, is well one year since beginning of treatment, with the tumor one-third the original size, and the element of malignancy apparently destroyed.

A sixth, recurrent sarcoma of leg and thigh, is still under treatment. The sarcoma of the stump, the size of a hen's egg, has entirely disappeared.

Of the remaining nineteen cases of sarcoma treated, nine others showed marked improvement, while in eight the improvement was very slight, and in two no improvement was noted.

Of the eight cases of carcinoma, all but one showed more or less improvement, and in three cases it was very marked.

All of the cases treated were inoperable and hopeless. In all, the diagnosis was not only established by eminent surgeons, but confirmed by expert pathologists.

No rational explanation of the action of the toxines upon malignant tumors could be offered, except on the assumption that such tumors were of micro-parasitic origin. Admitting this theory, evidence in favor of which is steadily increasing, explanation would be easy, namely, antagonistic bacterial action.

The conclusions drawn from the cases treated, were as follows:

(1) The curative action of erysipelas upon malignant tumors is an established fact.

(2) This action is much more powerful on sarcoma than carcinoma.

(3) This action is chiefly due to the soluble toxines of the erysipelas streptococcus, which toxines may be isolated and used with safety and accuracy.

(4) This action is greatly increased by the addition of the toxines of bacillus prodigiosus.

(5) The toxines, to be of value, must come from very virulent cultures and must be freshly prepared.

(6) The results obtained from the use of the toxines, without danger, are so nearly, if not quite, equal to those obtained from an attack of erysipelas, that inoculation should rarely be resorted to.

VENOUS TUMOR OF THE DIPLOË,

by DR. LEWIS S. PILCHER, of Brooklyn.

The case reported differed from others which had been described, in that the tumor did not communicate with the longitudinal sinus, but was essentially a large venous cavity into which numerous diploic veins opened. The patient was a girl, aged fifteen years. When five years of age she fell and struck the top of her head. Within a few days a small, soft swelling was noticed at the site of injury, without pain or tenderness. This gradually increased in size. At the end of five years, it was lanced and a small quantity of clotted blood extruded. It immediately refilled. It was repeatedly opened, with the same result. She came under the observation of the author in 1894. At this time there was a prominent tumor over the site of the anterior fontanelle, about two-and-one-half inches in its largest diameter. Over the convexity of the tumor the skin was thin and without hair. In the right anterior quadrant of the base an elevated plate of bone could be felt. The tumor was soft, and could be diminished very slightly in size. It was gradually enlarging. On March 14th the author operated for the relief of this condition. The tumor was opened. In the anterior part of the base the cranial bone was wanting and over a space of two-and-one-half by one-and-one-half centimetres the dura mater was exposed. Certain venous channels of the diploë were seen to be opened, and from these free bleeding took place. The overhanging bone edge was cut away with bone forceps, the base of the cavity was well curetted, the cavity packed with iodoform gauze, and as far as possible the wound was sutured. No complication disturbed the after-course of the case.

STRANGULATION OF MECKEL'S DIVERTICULUM CAUSED BY VOLVULUS OF THE ILEUM.¹

J. W. ELLIOT, M.D., of Boston, read a paper on the above subject.

FOURTH DAY. — FRIDAY.

MOOTED POINTS AS TO FRACTURES OF THE ARM, WITH NOTICE OF AN IMPROVED SPLINT,

by J. MCFADDEN GASTON, M.D., of Atlanta, Ga.

The purpose of the paper was to ask attention to practical considerations touching the treatment of fractures near the articulations of the arm. In cases of fracture complicated with dislocation, the author saw no advantage in first setting the fracture, but preferred to reduce the dislocation before treating the fracture, and efficient means should be taken to prevent the recurrence of the dislocation.

With regard to fractures at the wrist, the only one in which there is any notable diversity of opinion is Colles' fracture, which occurs from half an inch to one inch from the carpal articulating surface. In most cases the adjustment can be effected by extension upon the hand and pressure over the projecting lower fragment, but there is usually difficulty in maintaining apposition. The apparatus for Colles' fracture should control any movement of the wrist or of the fingers. This is effectually accomplished by the splint originally

adopted by Nelaton. The dorsal and palmar Nelaton splints keep the fragments in their proper position, and with the extension effected by the pistol-handle-shaped splint, all the requirements are met. The injunction to leave the fingers exposed, that movements of these and of the carpal bones may accompany the treatment, is more likely to increase the local inflammation than the rule to maintain complete rest. Early movement of the fingers and of the carpal joint must increase the tendency to subsequent stiffness. After considerable experience with the double pistol-handle-shaped splint in the treatment of Colles' fracture, the author had never seen a case in which there has remained any permanent impairment of the use of the fingers or the wrist-joint, nor had any material deformity followed the treatment.

Dislocation of the head of the radius or the upper part of the ulna is frequently observed in connection with fractures of the lower extremity of the humerus. These require correction before the fracture is treated. In considering whether the arm should be dressed in the extended or flexed position, we should investigate thoroughly the bearings of the different modes of treatment when there is likely to be such inflammatory involvement as so induce ankylosis. A stiff arm in the extended position is practically useless, while in a flexed position it is of much service. While it is held that with proper precautions ankylosis should not occur, yet there are cases with such complications that ankylosis will ensue in spite of the best treatment. Where the surgeon cannot reasonably expect to avoid ankylosis, there is no question as to the necessity of treating the arm in an angular position. The practicability of maintaining the fragments in position where the fracture involves the articulation, is favored by the relaxed rather than by the extended position. The rather fanciful claim in favor of the extended position being favorable to the preservation of the outward angularity of the forearm upon the arm is not entitled to any special consideration, as there is nothing in the flexed position to interfere with the relation of the radius and ulna to the humerus. The comfort and convenience of dressing the arm in the flexed position also commend themselves. The author considered the use of a straight splint applicable only in fractures of the olecranon.

In the treatment of fractures near the elbow, the author applies a roller bandage from the fingers to above the seat of injury, and with the arm in a flexed position pasteboard splints are moulded to its inner and outer surfaces. These splints extend from the wrist to the shoulder. An internal angular splint is applied to the outside of the dressing until the pasteboard has become thoroughly dry. This dressing has all the advantages of plaster-of-Paris and can be removed daily if it is so desired. The results of this method have been entirely satisfactory.

Fractures near the head of the humerus may be intercapsular or may only implicate the tubercle outside of the capsule. The most frequent seat is through the surgical neck. It is for this class of cases that a special splint has been devised by the author, the object being to effect extension and counter-extension and keep the fragments in place and at rest. The splint is formed with a right angle in the plane of the board at the elbow, the upper branch extending into the axilla with a crutch-like termination, and the lower branch reaching the wrist. When fitted to the inner face of the

¹ See page 286 of the Journal.

arm and secured with a bandage, with a light board splint moulded to the outer aspect of the arm, all the conditions are met for retaining the fragments accurately in apposition. The arm is to be kept close to the body. The crutch-shaped branch is the special feature of this splint. Several cases were reported in which the splint had been used with success.

THE REMOVAL OF STONE IN THE BLADDER, WITH THE PRESENTATION OF A NEW LITHOTRITE,
by DR. W. S. FORBES, of Philadelphia.

The points considered were :

- (1) The measured crushing resistance of vesical calculi.
- (2) The lithotrite from a mechanical point of view.
- (3) The measured strength of the lithotrite.
- (4) A new lithotrite.

A table was given of the size, displacement, specific gravity and measured crushing resistance in pounds and ounces of 183 human vesical calculi. The strongest calculus in this group took, on the testing machine, four hundred and six pounds to crack it. Several took upward of three hundred pounds to crack them. In testing the strength of the lithotrites on the testing machine, the strongest lithotrite (No. 83 F., made by Tiemann & Co.) had the female blade bent at six hundred and fifty pounds. A Thompson lithotrite (No. 29 F., made by Weiss, London), bent badly at three hundred and thirty-three pounds, on the same testing machine. The practical bearing of these observations is, that the strength of the lithotrite may be tested and stamped on it, before it leaves the instrument maker's shop, thus enabling the surgeon to begin his operation knowing the strength of the lithotrite.

The testing apparatus for determining the force required to crush the stone and the strength of the lithotrite was exhibited and demonstrated. The apparatus was the invention of Mr. John S. Forbes, son of the author. Mr. Forbes has also devised a new lithotrite designed to furnish a stronger instrument and obviate some of the defects of former instruments.

EXTIRPATION OF THE LARYNX,

by WM. H. CARMALT, M.D., of New Haven, Conn.

In this case the operation was done in such a way as to permanently close the opening into the mouth, so that there should be no communication with the lungs. He was induced to do this by his knowledge of a case in which the larynx was extirpated and the opening to the mouth subsequently closed. The operation was done two and a half years ago by Dr. J. Solis Cohen, of Philadelphia, and the man gained the power of speaking loud enough to be heard in a large room. This was preceded by swallowing or drawing air into the pharynx.

Dr. Carmalt's case was that of a man forty-four years old. The patient came under observation with severe attacks of dyspnoea due to the presence of an ulcerated nodule in the larynx, which had been first discovered two years ago. The dyspnoea necessitated the performance of tracheotomy. The larynx was extirpated March, 1894. The upper portion of the oesophagus was stitched to the epiglottis. On the second day he was able to swallow fluids, and made an uneventful recovery. The patient is now able to speak in a whispered voice.

DR. JARVIS S. WIGHT, of Brooklyn, exhibited a number of instruments, including needle forceps, self-

threading needle, aneurism needle forceps, and a new form of knife provided with a beak substituting the use of a grooved director.

The following papers were read by title: "The Effect of Erysipelatous Attacks on Tuberculosis," by Dr. DeForest Willard, of Philadelphia; "Hernia," by Dr. W. T. Bull, of New York; "Cases of Extra-Uterine Pregnancy, with Remarks," by Dr. M. H. Richardson, of Boston; "Treatment of Urethral Vegetations by a Circular-cutting Curette," by Dr. John B. Deaver, of Philadelphia; "Report of Surgical Cases," by Dr. Chas. B. Porter, of Boston.

STATE MEDICAL SOCIETY OF PENNSYLVANIA.

THE Forty-fourth Annual Meeting of this Society convened in Philadelphia, May 15th to 17th inclusive, the sessions being held in a vacant church building at Twelfth and Walnut Streets. Dr. H. G. McCormick, of Williamsport, was President. There were 520 names of delegates and members enrolled upon the register, making it the largest meeting in the history of the organization. It may also be said that the programme, under the efficient management of the Committee on Arrangements, Dr. E. E. Montgomery, Chairman, was the best ever presented to the Society. Unfortunately, so many papers had been prepared that more than half had to be read by title only, and there was but scanty time to discuss others, even on most important topics. As the rule, the contributions were on practical clinical subjects and in quality were excellent; in consequence, the forthcoming volume of transactions will be of more than usual value.

Addresses of Welcome were delivered by Hon. Edwin S. Stuart, Mayor of Philadelphia, and by Dr. E. E. Montgomery.

The Secretary of the Society reported a total membership of 2,500, with an increase greater than the average during the past year. The Treasurer, Dr. Geo. B. Dunmire, reported a balance on hand of nearly two thousand dollars, all expenses for the year having been met.

Dr. H. G. McCormick, Chairman of the Legislative Committee, reported the enactment of a law establishing a State Medical Council and three State Boards of Examiners and Licensers. The first examination of physicians for authorization to practice in Pennsylvania, will be held in Philadelphia and Pittsburgh on June 11, 1894. In order to aid the State Board in its work, the following resolutions, prepared by a committee, were submitted and adopted :

Resolved, That the Secretary of each county society is requested to forward at once to the Secretary of the State Board of Medical Examiners a correct list of registration of doctors under the last Act, on and from the 1st day of March last, and quarterly thereafter; and in communities where there are no county societies, the President of this Society shall appoint a member of this Society living in such county to procure such list, and in any case of neglect by either the officers aforesaid or the appointee to send such a list, the Secretary of the State Board of Medical Examiners of this Society shall be empowered to procure the same; and further be it

Resolved, That we recommend that \$500 of the moneys of the Society, or so much thereof as may be necessary, be appropriated for the examination of the registration of physicians in this State, with the view of enforcing the

Medical Examiners' Act lately passed, said money to be expended only under the direction of the State Board of Medical Examiners representing this Society, and that they shall approve all bills before being paid. Further, that the said Board of Examiners report at the annual meeting of this Society their action and expenditures under this resolution.

A resolution was also unanimously passed calling upon the Medical Council and State Boards in all their publications to refrain from applying any sectarian designations to members of this Society or candidates from regular colleges applying for examination. The Luzerne County Medical Society also entered a formal protest at this meeting against the use of the word "alopath" in the public prints, to designate non-sectarian physicians.

The Trustees of the *Journal of the American Medical Association* were criticised severely for permitting quack advertisements and other unethical matter to appear in the *Journal*. With regard to the proposal to alter the Code of Ethics (which will come up at the San Francisco meeting) this Society unanimously voted to instruct its delegates to oppose any alteration in the National Code.

The subject of "The Care and Treatment of the Insane and the Organization and Construction of Hospitals for the Insane" was brought up by Dr. Hiram Corson, and was referred to the Committee on Legislation. At its last session, a committee had been appointed to memorialize the Legislature on this subject, and the Senate had passed the bill proposed by this committee, but it had been lost in the House of Representatives. This committee reported as above stated, and was discharged.

Dr. J. A. Lippincott, of Pittsburgh, Chairman of Committee on Contagious Ophthalmia, reported that circulars had been sent to prominent ophthalmic surgeons throughout the State soliciting co-operation. The committee urged the careful inspection of immigrants at ports of entry, for *trachoma*, and proper treatment of all such cases. The great danger lies in the general ignorance of the gravity of the disease. Dr. George M. Gould offered resolutions with regard to the legal restriction of ophthalmia neonatorum, which was adopted.

Resolutions were also adopted deprecating the crippling of the army medical service by the proposed reduction of appropriations, which would not only greatly impair its efficiency, but would seriously imperil the very existence of the Army Medical School in Washington.

On the third day of the session considerable time was devoted to a discussion on Tuberculosis, which was the principal medical feature of the session. It was really opened by the Address in Hygiene, delivered by Dr. J. H. Wilson of Beaver, in which special attention was directed to the means recently proposed for restricting the communication of the disease by means of disinfection and isolation under the control of State and County Boards of Health.

Papers were read by A. M. Cooper on "Psychical Phases of Tubercular Folk"; by Lawrence M. Flick on "Prophylaxis"; by Thomas J. Mays on "Strychnine Treatment"; by Daniel Longaker on "Tubercular Meningitis"; by S. S. Cohen on the "Curability and Treatment of Pulmonary Tuberculosis." Dr. Wm. P. Munn, a delegate from Denver, read a valuable paper on "Colorado Climate" extolling its

comparative dryness, amount of sunshine, and freedom from infection. In the general discussion, Drs. J. S. Cohen, J. C. Wilson, J. M. Andrus and others participated. No less than six papers upon allied topics had to be read by title on account of the expiration of the time.

The paper that attracted most attention at this meeting (and the only one published *in extenso* in the newspapers), was read by Dr. Hildegard H. Longsdorf, of Carlisle; it was on "Christian Science in its Relation to the Medical Profession," and accounted for the existence of this mirage of modern medicine as a psychical manifestation, growing out of the love of mystery and the revolt from materialistic character of modern science. It is a "fad" especially liable to spread among a hyperæsthetic and ignorant leisure class, whose ills are largely neurasthenic, or entirely imaginary. On motion, a thousand copies of the address were directed to be printed for distribution to the laity, under authority of this Society.

A very interesting lecture on "Leprosy and the Loper Settlement in the Sandwich Islands" was delivered, by invitation, by Prof. Benjamin Sharp, M.D., of the Academy of Natural Sciences of Philadelphia. It was illustrated by photographs and lantern slides thrown upon the screen, which Dr. Sharp had made while on a visit last year to Hawaii. It forms a valuable contribution to the subject.

The Address in Surgery was delivered by Dr. G. D. Nutt, of Williamsport; that in Medicine, by Dr. W. F. Foster, of Pittsburgh; in Mental Diseases, by Dr. T. M. T. McKennan, of Pittsburgh; in Obstetrics, by Dr. E. E. Montgomery, of Philadelphia; and on Ophthalmology, by Dr. Geo. E. De Schweinitz, of Philadelphia.

The President's Address, by Dr. McCormick, was delivered in the evening, and was followed by a reception by the Faculty of the Jefferson Medical College at the Academy of the Fine Arts. Other entertainments were given by the Medico-Chirurgical College, the University of Pennsylvania, the Medical Club, and by the Philadelphia County Medical Society, the latter being a Theatre Party followed by a reception.

The following officers were elected for the year: President, Dr. John B. Roberts, of Philadelphia; First Vice-President, Dr. S. C. Stewart, of Clearfield; Second Vice-President, Dr. J. A. Lippincott, of Pittsburgh; Third Vice-President, Dr. J. H. Wilson, of Beaver; Fourth Vice-President, Dr. R. Armstrong, of Clinton; Secretary, Dr. Wm. B. Atkinson, of Philadelphia; Treasurer, Dr. Geo. B. Dunmire, of Philadelphia.

Next place of meeting, Chambersburg, Dr. George S. Hall, Secretary of Committee on Arrangements.

TUBERCULOSIS IN DOMESTIC PETS.—Professor Fröhner, of the Berlin Veterinary School, has recently made some investigations as to the prevalence of tuberculosis among small domestic animals, the results of which are as important as they are interesting. He finds it rare among dogs, somewhat more frequent among cats, and quite common in parrots. As the latter usually live in rooms constantly used by members of the family, their liability to tuberculosis makes them rather dangerous pets.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, JUNE 14, 1894.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMBELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE TWENTY-SECOND ANNUAL REPORT OF
THE BOSTON BOARD OF HEALTH.

THE annual report of the Boston Board of Health for the year ending January 31, 1894, contains, in addition to the usual valuable tables and charts, some interesting statements and some important recommendations. The death-rate per 1,000 inhabitants for the year was 24.02. Influenza is still held responsible in a great measure for the large increase in respiratory diseases. The prevalence of pneumonia during the year is reported as having assumed a character unequalled in the registration of vital statistics in this city.

In 1851, its percentage to the total mortality was 7.75; in 1893 it was 13.15 per cent., or a total of 1,540 deaths from this cause alone. On the other hand, the percentage of the total mortality from zymotic causes is less by .49 per cent. than for the year 1892, or 17.43 per cent. of the total number of deaths. The deaths from diphtheria increased 62, while the deaths from scarlatina decreased 14, as compared with the preceding year.

The Board finds that it is with the diseases over which control cannot be exercised that death claims the largest number of victims. The diseases of a constitutional character numbered 2,469, or 21.08 per cent. of the total mortality, and those of a local character, as pneumonia, bronchitis and heart disease, and the like, amounted to 5,712 deaths, or 48.77 per cent. of the whole number of deaths. There were also 572 deaths due to violent causes.

The number of children who died under five years of age was 3,987, or .80 per cent. higher than in 1892, but 1.15 per cent. less than the average for the previous ten years.

There was no epidemic during the year.

Some interesting items are given concerning the cases of small-pox which have occurred during the winter, exhibiting in a striking manner the value of vaccination. From October 30, 1893, to January 31,

1894, there were in all 36 cases. The percentage of deaths among the unvaccinated was 29.62. No vaccinated person died, and no vaccinated person was seriously ill. A mother nursed her infant, who had the disease, during the whole course of the attack, but the mother had two perfectly characteristic scars and did not contract the disease. Two vaccinated children, relatives of a patient, were constantly exposed from three to four weeks to the disease, and did not become ill. Of the 19 cases occurring in Ward 19, which were traced to an unrecognized attack of the disease, only one vaccinated person contracted it; and this patient, who had been vaccinated forty-five years ago, had such an extremely mild attack that, if it had not been for the existence of the other cases, the disease would probably not have been recognized.

The city of Boston made an extra appropriation of \$25,000 for free vaccination, and, in round numbers, about 100,000 persons were vaccinated under direction of the Board of Health. If one compares the condition of Boston to-day with that of Chicago in regard to small-pox, any candid person must recognize that the energetic action of the Board and the sum of money have been well spent, to the great advantage of this city and its inhabitants.

Under the head of "Contagious Diseases," the report draws a sharp and instructive contrast between what the Board has been enabled to do during the last twenty years in restraining and suppressing small-pox, and its enforced comparative helplessness in its relation to such diseases as diphtheria, scarlet fever and typhoid fever. During that period small-pox has diminished to almost nothing, whilst the other diseases have continued practically endemic, as during the preceding period of twenty years. During the last twenty years there have been only 34 deaths from small-pox, and during the same time there have been 8,245 deaths from diphtheria, 3,281 deaths from scarlet fever, and 3,376 deaths from typhoid fever. Against these diseases there is, as yet, no prophylactic treatment such as we possess in vaccination against small-pox. Early recognition and report of cases, isolation until all power to impart the disease is lost, and timely disinfection, are the means by which these diseases may be controlled. The proper application of these means involves expense.

The Board of Health has repeatedly asked for an appropriation with which to increase its care for the uncontrolled cases of diphtheria and scarlet fever, and it has as often been refused. "The Board would like to have all cases seen by its own physicians or agents, held under proper surveillance while at home, and released from isolation only on the certificates from the same physicians or agents. It would like to aid in having all doubtful cases of sore throat decided by expert bacteriological examinations, and have all cases of diphtheria discharged from isolation by means of the same tests, or after a prolonged isolation when all local and general symptoms of the disease have disappeared. To do this the department must have more

dical agents, and have its present medical officers relieved from duties now performed for other departments of the city."

In regard to diphtheria, the Physician of the Board, J. H. McCollom, emphasizes his conviction, as the result of careful personal study of the subject, that the manifest importance of a bacteriological investigation as a means of diagnosis in doubtful cases of diphtheria becoming more and more evident, and of no less importance, as far as the well-being of the community concerned, is the bacteriological investigation of cases after apparent recovery from diphtheria.

In an endeavor to diminish the prevalence of this disease, the two most important factors, in Dr. McCollom's judgment, are: first, the recognition of mild and doubtful cases; second, the actual disappearance of the special germs of the disease, which can only be recognized by means of a bacteriological investigation. In New York this conviction has reached the stage of practical application.

An appropriation of money for protection against the spread of infectious diseases does not furnish places for "workers" or work for voters; but there is absolutely no object through which an intelligent and faithful application of a sum of money, and that of moderate amount, can be made to yield such valuable returns to a community like that of Boston. Few will be found to deny this, and yet such an appropriation is not to be had. The city might even better be without a park or two, or at least without some of the very costly elaborations of a Park System!

SUNSHINE AND MICROBES.

PROF. PERCY FRANKLAND has written an article in the May number of the *Nineteenth Century*, on "Sunshine and Microbes," which is interesting as a summary of what has been discovered on the influence of the sun's rays on bacteria. The first and most important step in revealing the cleansing and disinfecting properties of sunshine was made sixteen years ago by two Englishmen, Downes and Blunt. They established the remarkable fact that if certain liquids capable of undergoing putrefaction were exposed to the direct rays of the sun, they remained perfectly sweet, whilst exactly similar liquids kept in the dark became tainted and exhibited innumerable bacteria under the microscope.

They also ascertained that the oxygen of the air is a powerful adjuvant to the bactericidal power of the sun's rays. Recently, M. Moment in Pasteur's Institute, has obtained more exact information confirming these experiments by exposing anthrax-bacilli to sunshine in the presence of and in the absence of air, with the result that while the anthrax-bacilli exposed to the sun and air were killed in two and a half hours, similar bacilli placed in a vacuum were still alive after fifty hours' exposure to sunshine.

The next problem to be attacked was to ascertain whether all the solar rays were equally responsible for

this important result, or whether the different colored rays composing the sun's beams produced different effects, as is known to be the case in those important vital processes which go on in green plants.

Geisler, of St. Petersburg, has given especial attention to this question. He decomposed the white sunbeams by means of the prism and then exposed typhoid bacilli to the light of the various parts of the spectrum. The rays of the red end he found had little or no effect at all on the growth of the bacilli, whilst the most powerfully deleterious action was obtained in the ultra-violet, the effect becoming less and less marked in passing from this to the red. The rays which exert this destructive or inhibitory effect on bacterial life are precisely those which also exert the most powerful action on the ordinary photographic plate.

Of much interest also is the comparison made by Dr. Geisler of the potency of the sun and the electric lights respectively in destroying bacterial life. His experiments have proved the striking inferiority in this respect of the most dazzling of artificial lights in comparison with sunshine.

Even if exposure to the solar rays is not sufficient to actually destroy the bacteria, it may yet profoundly modify their character, and bring about the most important changes in their subsequent behavior. Thus, while many bacteria can produce the most wonderful colors — yellow, orange, scarlet, crimson, indigo-blue, etc., it has been found that exposure to sunshine for a short time is able to rob them of this beautiful property.

Much hygienic importance and interest attaches to some recent investigations of Dr. Palermo, of Naples. The microbe selected for experiment was Koch's cholera bacillus. These bacilli are fatal to guinea-pigs in about eighteen hours. Dr. Palermo placed some of these bacilli in the sunshine for various periods of time, and found that whilst, when he protected them from the sun, they killed guinea-pigs in eighteen hours as usual, after they had been "sunned" for from three-and-a-half to four-and-a-half hours, they were perfectly harmless, and the animals experienced no evil results whatever from inoculation with them.

The cholera bacilli which refused to kill the guinea-pigs had not been destroyed, nor had their total number suffered any diminution, but their inability to work mischief was directly due to the removal *during this exposure to sunshine of their virulence or disease-producing powers*. More than this, it was found that those guinea-pigs which had survived the inoculation with these sunshine-exposed bacteria had acquired immunity toward the disease. Thus, when eight days later they were inoculated with *virulent* cholera bacilli, they were unaffected by doses which to ordinary guinea-pigs proved rapidly fatal.

Dr. Frankland has experimented to ascertain the action of sunshine on the spores of anthrax suspended in water, and has found that in this medium they are able to survive as much as one hundred hours or more

of full sunshine, whilst in ordinary culture materials, like broth and jelly, they are generally killed by a few hours exposure to the sun's rays. He has also found that the addition of common salt greatly increases the destructive action of sunshine on anthrax spores.

In order to ascertain the effect of daylight on the bacteria of a running stream, two young German bacteriologists lately carried on an interesting experiment on the river Isar near Munich. They sat a whole night by the river bank, from six in the evening till six on the following morning, determining the number of microbes in the water at various intervals of time. The experiments were made towards the end of September, and they commenced their watch about sunset at a quarter past six in the evening. At this time, one hundred and sixty bacteria were found in twenty drops of water; but at three and four o'clock in the morning, when the water had therefore been for several hours in darkness, there were more than twice and even three times that number of germs present, indicating that in the absence of their deadly foe, the sunshine, they had multiplied with great freedom — only, however, as was found when morning approached and day wore on, to be kept once more in subjection and reduced in number.

These experiments were, of course, made with water taken from the superficial layers only, but it is obviously of particular interest to ascertain whether this destruction of bacteria can take place also beneath the surface of the water, and if so, to what depth the sun's rays can exercise this inhibitive power.

MEDICAL NOTES.

A NEW MORGUE FOR PHILADELPHIA. — The Department of Public Safety of Philadelphia has completed the new city morgue on Wood Street, Philadelphia, and the building was open to physicians' inspection on June 1st.

A ROYAL METHOD OF PAYING THE DOCTOR. — A correspondent of the *Medical Record* sends the following anecdote, which the late Prof. Edward Jäger, of Vienna, related of his father (at that time the first oculist in Europe), and of Milosh Obrenovich, who then was the first Prince of Servia: "Milosh had cataract of both eyes. Jäger operated for him on one eye with good result. Milosh paid for this operation 6,000 ducats (nearly \$10,000). When Jäger had operated on the second eye, and the result was happy again, Milosh sent him this time 8,000 ducats. Later they met at the table of Prince Metternich, and were seated one next to the other. Jäger asked his neighbor why he had only given him 8,000 ducats for the second operation. Milosh, with the cunning smile of a savage or a peasant, answered: 'If I had had a third eye to be operated on, I would no doubt have paid you again 6,000 ducats for the second operation.' May not his sublime Highness, the Shah of Persia, feel inclined to play a similar trick on Dr. Galezowsky?"

"WHAT SHOULD A DOCTOR BE PAID?" — This is the subject discussed by Dr. W. A. Hammond in the June number of the *North American Review*. Our readers will be glad to learn that, under certain circumstances, \$500,000 would be a moderate fee. The *Lancet* (June 2d) publishes an address by Dr. Dickinson, on "Professional Remuneration." Dr. Dickinson's treatment of this topic is less exhilarating.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — During the week ending at noon June 13, 1894, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 39, scarlet fever 56, measles 15, typhoid fever 5.

BOVINE TUBERCULOSIS AT THE MASSACHUSETTS STATE INDUSTRIAL SCHOOL. — A second herd of imported cattle at the State Industrial School at Lancaster has been found affected with tuberculosis and the cattle have all been killed.

MEDICAL REGISTRATION LAW. — The Medical Registration Bill has passed both branches of the Massachusetts Legislature and received the Governor's signature. The full text of the bill has already been published in the JOURNAL.

THE ROCKLAND, ME., SMALL-POX HOSPITAL BURNED. — The house selected by the Rockland, Me., Board of Health for a small-pox hospital was burned June 8th. It is supposed that the fire was set by some one opposed to a quarantine hospital in that locality as the neighbors had already made much complaint of the selection.

SUFFOLK DISTRICT BOARD OF CENSORS. — The Board of Censors of the Suffolk District Medical Society will hold an adjourned meeting for the examination of candidates for the Massachusetts Medical Society on June 26th. This meeting is held for the convenience of students now taking their final examinations in the Medical School.

THE BOSTON CITY HOSPITAL CLUB. — The Executive Committee of the City Hospital Club has voted that in future the annual dinner of the Club be held some time during the winter months, instead of in June, as has been the case heretofore. It has been decided to hold the next dinner on the first Wednesday in February, 1895. It is proposed to make the annual meeting of the Club coincident with the dinner. No quorum being present at the annual meeting called for Tuesday, June 12th, an adjournment was voted to the first Wednesday in February, or subject to the call of the Executive Committee.

MRS. AMORY'S BEQUESTS TO HOSPITALS. — The will of the late Mrs. Jeanne P. Amory of Braintree directs the executors to sell within two years all her right, title and interest in the real estate at 111 West 57th St., New York City, and to divide the net proceeds equally between the Massachusetts General Hospital

in Boston, the City Hospital in Quincy, Mass., the Woman's Hospital and the Skin and Cancer Hospital, both in the city of New York.

THE NEW CONTAGIOUS HOSPITAL AT WALTHAM, MASS., NOT ACCEPTED BY THE BOARD OF HEALTH.—At its recent meeting the Waltham Board of Health refused to make use of the new contagious hospital on the ground that there are serious defects in its construction which render it unserviceable. The reasons they give are: first, that there is no cellar; second, there is no adequate method of heating; third, no provision has been made for proper ventilation; fourth, that the diphtheria and scarlet fever wards are too near each other; fifth, that there is no satisfactory method of procuring hot water. The desired alterations are estimated to cost over three thousand dollars.

THE MASSACHUSETTS DENTAL SOCIETY.—The Massachusetts Dental Society held its annual meeting in Boston on June 7th, 8th and 9th. The following-named officers were elected for the ensuing year: President, J. King Knights, D.D.S., of Hyde Park; First Vice-President, George A. Maxfield, D.D.S., of Holyoke; Second Vice-President, Waldo E. Broadman, D.M.D., of Boston; Secretary, Edgar O. Kinsman, D.D.S., of Cambridge; Treasurer, Edward Page, M.D., D.M.D., of Charlestown; Librarian, Thomas W. Clements, D.D.S., of Brookline; Executive Committee, Harry S. Draper, D.D.S., George C. Ainsworth, D.D.S., Joseph T. Paul, D.M.D., all of Boston; H. P. Cooke, D.M.D., of Worcester, and Robert T. Horn, D.D.S., of Brookline.

NEW YORK.

FATAL POISONING FROM WATER HEMLOCK.—Five ladies were fatally poisoned and six others made seriously ill at the Institute of the Sisters of Mercy, at Tarrytown on the Hudson, on June 4th, by eating what they supposed to be sweet-flag root. The root, which was dug up by laborers engaged in laying some drain pipes in the grounds of the institution, has been pronounced by Dr. N. L. Britton, Professor of Botany in Columbia College, and Dr. H. R. Rusby, Professor of Botany in the New York College of Pharmacy, to be that of the water hemlock. In most of the fatal cases death resulted within half an hour after the poisonous herb was eaten.

REPORTED DEATH FROM VACCINATION PROVES TO BE UNTRUE.—A short time since the announcement was made in the newspapers that a child three years of age had died from the effects of vaccination by one of the Board of Health's corps of vaccinators. The case was referred to the coroner's office for the death-certificate, as the attending physician had seen the child too short a time before its death to feel justified in making a certificate. The deputy coroner reported that death was due to tetanus induced by septicæmia which was the result of vaccination. The Board of Health felt satisfied that death was due to other causes, and ordered an investigation. On inquiring of other physicians who had seen the child, it appeared that the

cause of death was most probably a traumatic meningitis. An autopsy confirmed this diagnosis, and the coroner filed a new certificate of death from "Exhaustion resulting from convulsions from acute meningitis due to a fall."

Miscellany.

OPERATIVE SURGERY UNDER DIFFICULTIES.

THE recent death of Mr. Dickinson Crompton recalls the following story¹ of a surgical operation which he performed in his earlier years under great difficulty. He told the anecdote as follows:

"Some years ago I was called in the night to go to M—— to an accident, prepared to amputate. I found a poor laborer lying on his cottage bed, his left arm hanging over the edge of the bed, dropping blood into a chamber pot. The arm was black, as if it had already mortified. I heard that the man's arm had been caught in the cog-wheel of one of the agricultural machines, and was drawn in up to the shoulder. There was nothing for it but amputation above the injured part—in fact either close to the head of the humerus or by disarticulation of the whole. There was no room for a tourniquet, and I requested Mr. C., the surgeon of the village, to press upon the artery against the head of the bone.

"There was a boy in the room—an apprentice, I was told—but he declined to come near the patient to hold out the arm. I was therefore obliged to hold the artery against the head of the bone with my left hand, while Mr. C. held the arm out at full length by the hand; but he told me he always 'fainted at the sight of blood'; so turning his face and body away as far as possible, he held on till I had made my incision and sawn through the bone as high as I could.

"There was only a cottage candle in the room, and therefore I asked Mr. C. to hold it, so that I could look for the arteries, but he had had enough.

"The poor patient was sitting on a chair making no complaint; in fact I think there could not have been much pain felt, from the appearance of the parts; so he himself said, 'Sir, if you will give me the candle, I think I can hold it.' This he did, bringing his right hand round with the candle in it, so that I had a good view of the face of the stump. I was delighted to get my tired thumb and hand free, when I saw the orifice of the brachial and could pull it out by the tenaculum, and left it hanging till I could tie the artery, and so with the smaller vessels. After that I had no further difficulty, as only one or two small arteries seemed inclined to bleed.

"The man recovered, but I heard he died of phthisis six months afterwards."

THE FIRST EPIDEMIC OF MEASLES IN SAMOA.

THE virulence of a first epidemic of measles among a new race is well known, but actual occurrences under medical observation are not so common as to be uninteresting. Dr. S. H. Davies of Savaii, Samoa, publishes a brief account of the first epidemic of measles in that group of Islands.²

"It was brought first to Tonga in June, 1898, where

¹ Birmingham Medical Review, May, 1894.

² Australian Medical Gazette, April, 1894.

it nearly decimated the population. Three months later the same vessel brought the disease to Samoa. The entire population of the ten inhabited islands of the Samoa group is about 34,500; and by the first of this present year fully one thousand persons had died from measles, nearly half being adults. The epidemic was mild in its onset, and comparatively few died during the period of fever and eruption.

"The mortality from measles has arisen principally from the complications of gastritis, enteritis, diarrhoea and dysentery. A few died from suppressed measles. But the craving the natives have for raw fish, unripe or over-ripe fruit, and especially half-cooked *fresh pork*, became morbid during the period of convalescence. Many, lest they should be told to abstain from these, avoided foreign medicine. Nine-tenths of the deaths might have been prevented by care in diet. The worst cases of diarrhoea and dysentery yielded to treatment, and there were no deaths among those who followed instructions, and who were under one's own personal supervision. Since measles arrived, an unusually large number of these people including many adults, with their usual predisposition to scrofula, have suffered from the suppurating glands in the neck, submaxillary region and groin. Not a few had parotitis, going on to suppuration. During period of fever and rash there were numerous abortions. Single and multiple abscesses are very common at all times, but cases have been multiplied tenfold of late. Now that nearly three months have elapsed since last cases of fever and rash, a mild form of remittent fever is exceedingly common."

"The two epidemics of influenza in 1891 and 1893 increased the natural tendency of the Samoans to chest affections, and the measles has still further intensified their susceptibility. During the past two months two hundred persons, at the very least, have died from the effects of the measles epidemic which will be long remembered, as not one of the whole population seems to have escaped."

THERAPEUTIC NOTES.

THE INTERNAL TREATMENT OF VESICULAR ECZEMA.—Dr. Leslie Phillips writes to the *British Medical Journal* the results of observations made during the last two years on the effect of certain remedies given in the hope of obtaining some specific or direct action in modifying the morbid tendency of vesicular eczema in adults. Calcium sulphate was perseveringly employed in a large number of cases, always with a disappointing result. Ichthyol in pills seemed to have a slight modifying influence in one or two cases. Calcium chloride and thyroid glands both gave negative results. The hypophosphites appeared to be occasionally useful. Tartarated antimony was very helpful in not a small proportion of cases. It was given in sensible doses; namely, one-tenth to one-sixth of a grain thrice daily, and continued for long periods, it being seldom found needful to discontinue it on account of ill-effects.

TREATMENT OF DIPHTHERIA AT THE HOSPITAL TROUSSEAU.¹—The staff at the Hospital Trousseau in Paris, after trying various methods of treating diphtheria, has settled upon the following routine practice for exclusive use in all cases of diphtheria or doubtful angina, which is treated as diphtheria pending bacterio-

logical cultures. The local treatment consists in large irrigations with solutions of carbolic acid in the strength of 1 to 150 or 200, and in the application of an antiseptic varnish. These are used in all cases and stages of the disease. The douches are especially insisted on in septic cases. The false membrane is wiped away as much as possible by pledgets of absorbent cotton. The carbolic solution, tepid, is thrown from an irrigator directly upon the denuded area, and is afterwards run through each nostril until it returns clear. The varnish is applied by swabs of absorbent cotton upon the false membrane which is not detached, or the place it once occupied. The formula is:

2	Gum lac. (purified, wholly soluble in alcohol)	270 grammes
	Benzoin (purified, wholly soluble in alcohol)	10 "
	Balsam tolu	10 "
	Crystallized carbolic acid	100 "
	Essence of cinnamon	6 "
	Saccharine	6 "
	Alcohol to make one litre.	

The varnishing is repeated, according to the gravity of the case, every two or four hours during the day and every three or six during the night. In all cases the douching is repeated every two hours during the day and every three or four at night. "The application is naturally opposed by the child, but in view of the seriousness of the disease force is to be used if necessary. Accordingly, two or three persons are needed to immobilize the patient and hold the mouth open. On the first sign in the urine of carbolic intoxication the solution is to be changed for one of thymol or salicylic acid." The general treatment consists in (1) tonics (alcohol and quinine); (2) diuretics, to aid in the elimination of the diphtheria toxine; (3) caffeine or sparteine, for cardiac weakness; (4) a diet of milk, eggs or broth.

TREATMENT OF WHOOPING-COUGH BY QUININE.—Baron¹ recommends the use of quinine in pertussis, and from a study of some fifty cases draws the following conclusions. In a small number of cases a favorable effect is obtained very early, even as soon as the second or third day. In most cases the result is doubtful for the first few days because the larger number of the children have a tendency to vomit and an uncertain amount of the drug is retained. From the fifth or sixth day a decided improvement, both as regards the number and severity of the paroxysms, is noticed. This improvement advances rapidly and continuously even though the quinine is given in gradually smaller and less frequent doses. The time required for a cure by this method is given as not over three weeks, and in some cases is so short as to almost warrant calling the treatment abortive. The administration is advised after the following manner: Each single dose of the hydrochlorate of quinine is estimated at 0.01 gm. for each month and 0.1 gm. for each year of the child's age. This is to be given three times a day, preferably at 6 A. M. and 2 and 10 P. M. Strong babies, as a rule, require a somewhat larger dose than that scheduled for their age, while even children over four years of age rarely need more than 0.4 gm. t. i. d. Upon a manifest amelioration of the symptoms two doses daily only are needed with a gradual lessening of each dose. A single dose at night-time should be given for some time after apparent full recovery. The quinine may be given in solution (not advised, owing to the varying size of spoons used), in capsule or in sugar pellets.

¹ L'Union Médicale.

¹ Berlin klin. Wochenschrift, 46, 1893; Deutsche Med. Zeitung, 24, 1894.

The chocolate and quinine candies might seem to be of use. Especial importance is attached to a continuance of the treatment for a few days beyond apparent cure, to lessen any chance of too early omission of treatment.

Correspondence.

WEIGHT AS A SYMPTOM IN PHTHISIS.

DENVER, COL., June 4, 1894.

MR. EDITOR:—I wish to offer a few suggestions as to the method of treatment of phthisis discussed by Dr. Boardman in your issue of May 17th.

To me it seems that not sufficient stress has been placed upon one sign in the summary of the condition of the patient after the treatment mentioned. I refer to the gain or loss of weight. I believe that physicians are coming more and more to the belief that this one factor is of infinitely more importance than all others together in estimating a patient's progress, and a fatal objection to the method of treatment mentioned is, as I see it, that in only one of the ten cases given in detail was there any gain of weight, and in that one this gain amounted to only three pounds. One case held his own, and the other eight cases lost an aggregate of thirty-two and three-fourths pounds, or an average of more than four pounds each, in a treatment averaging a little over two months. The temporary gain which was lost before the end of the treatment, is not considered in this computation.

In an experience of more than a decade in the treatment of this disease in Colorado, I have become more and more impressed with the fact that those patients in whom a gain in weight is observed, generally do well, while those cases in which a loss occurs, no matter how gradual, do badly in the end. It is my custom to inform patients who complain of this or that symptom, that, so long as the gain in weight, which we generally see in incipient cases here, continues, I do not care very much about the other symptoms.

In our anxiety to establish the bacillary origin of this disease and to found a treatment upon this discovery, we have been in danger of losing sight of the one fundamental fact which underlies the whole matter, namely, that this disease is one in which the patient is on the road to physical bankruptcy. We all recognize the fact that, in the absence of this essential condition, the bacillus does not thrive in the human organism. Practically, the patient's salvation, when attacked, lies in an improved assimilation of food. When placed under such conditions as enable him to hold his own, and then to begin to gain in weight, we have, in this gain, a form of evidence that he is overcoming his bacillary antagonists, which is infinitely better than any which can be obtained in the laboratory. As well assume that a suspected bank must be all right because of the acquisition of a new set of office furniture, in spite of the known fact that its cash account is running behind, as to consider a case of phthisis improving because of improvement in certain symptoms when the weight is decreasing.

I do not mean to intimate that the writer has, by any means, attempted to lead us to believe that this treatment is better than other recognized methods, but merely wish to point out the fact that an important factor in estimating the true value of this or any other means of treatment of phthisis has been passed over too lightly in this contribution. To those of us who have repeatedly seen patients gain twenty-five or even fifty pounds of flesh in this climate, coincidently with the recovery of health, the idea of improvement without decided gain in weight in tuberculosis seems preposterous.

We are all under obligations to Dr. Boardman, however, for his careful record of the cases he has presented.

Yours very truly,

1517 State St.

J. N. HALL, M.D.

METEOROLOGICAL RECORD.

For the week ending June 2d, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Deaths reported 2,227: under five years of age 816; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fever) 366, consumption 283, acute lung diseases 278, diphtheria and croup 161, diarrhoeal diseases 69, scarlet fever 36, whooping-cough 32, typhoid fever 18, measles 17, cerebro-spinal meningitis 15, small-pox 7, erysipelas 6, malarial fever 5.

From whooping-cough Brooklyn, Washington and Pittsburg 6 each, Philadelphia 5, New York 3, Fall River 2, Boston, Cambridge, Lynn and Somerville 1 each. From typhoid fever Philadelphia 7, Washington 3, Brooklyn, Pittsburg and Worcester 2 each, New York and Nashville 1 each. From measles New York 6, Philadelphia and Brooklyn 4 each, Pittsburg 3. From cerebro-spinal meningitis New York 8, Worcester and Lynn 2 each, Boston, Brockton and Chelsea 1 each. From small-pox New York 6, Brooklyn 1. From erysipelas New York 3,

Philadelphia, Brooklyn and Boston 1 each. From malarial fever New York 2, Philadelphia, Brooklyn and Fall River 1 each.

In the thirty-three greater towns of England and Wales with an estimated population of 10,458,412, for the week ending May 26th, the death-rate was 17.7. Deaths reported 3,543: acute diseases of the respiratory organs (London) 248, measles 248, whooping-cough 128, diphtheria 62, scarlet fever 41, diarrhoea 38, fever 31, small-pox (London 7, West Ham and Birmingham 2 each) 11.

The death-rates ranged from 10.1 in Plymouth to 28.4 in Salford; Birmingham 18.6, Bolton 16.7, Croydon 11.2, Hull 14.2, Leicester 15.2, Liverpool 20.9, London 17.3, Manchester 22.1, Newcastle-on-Tyne 18.8, Nottingham 21.0, Sheffield 17.4, Swansea 14.8, Wolverhampton 21.5.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 2, 1894, TO JUNE 8, 1894.

Upon being relieved from duty at Camp Merritt, Montana, by FIRST-LIEUT. WILLIAM H. WILSON, assistant surgeon, FIRST-LIEUT. EDWARD L. MUNSON, assistant surgeon, will proceed without delay to Fort Yellowstone, Wyoming, and report to the commanding officer for temporary duty with troops in the National Park during the season.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JUNE 9, 1894.

GEO. A. BRIGHT, medical inspector, detached from U. S. S. "Newark," ordered home and granted three months' leave.

R. A. MARMION, surgeon, detached from Smithsonian Institution and ordered to the U. S. S. "Newark."

D. McMURTRIE, medical inspector, ordered to the Smithsonian Institution.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE FIVE WEEKS ENDING MAY 26, 1894.

MURRAY, R. D., surgeon. To proceed to Brunswick, Ga., for special duty. April 30, 1894. To proceed to Waynesville, Ga., as inspector. May 17, 1894.

HUTTON, W. H. H., surgeon. Detailed for duty as inspector of Quarantine Stations. April 27, 1894.

HAMILTON, J. B., surgeon. Granted leave of absence for three days. May 14, 1894.

GASSAWAY, J. M., surgeon. Granted leave of absence for fifteen days. May 12, 1894. Leave of absence extended five days. May 26, 1894.

STONER, G. W., surgeon. To inspect Cape Charles Quarantine Station, monthly. April 27, 1894. Granted leave of absence for thirty days. May 18, 1894.

GODFREY, JOHN, surgeon. To represent the service at meeting of the American Medical Association at San Francisco, Cal. May 11, 1894.

IRWIN, FAIRFAX, surgeon. To proceed to Berlin, Germany, for special duty. May 5, 1894.

CARTER, H. R., surgeon. Granted leave of absence for three days. May 3, 1894. To proceed to Key West Quarantine for temporary duty. May 4, 1894.

BANKS, C. E., passed assistant surgeon. Granted leave of absence for five days. May 1, 1894.

CARMICHAEL, D. A., passed assistant surgeon. To proceed to St. Louis, Mo., for temporary duty. May 15, 1894.

PECKHAM, C. T., passed assistant surgeon. To proceed to San Francisco Quarantine Station for duty. May 17, 1894.

GLENNAN, A. H., passed assistant surgeon. To proceed to Wilmington, Del., for special temporary duty. April 26, 1894.

WHITE, J. H., passed assistant surgeon. To inspect quarantine Stations. April 27, 1894. Granted leave of absence for seven days. April 29, 1894. Granted leave of absence for twenty-three days. May 4, 1894.

BRATTON, W. D., passed assistant surgeon. To report at Bureau and then to proceed to Delaware Breakwater Quarantine for duty. May 19, 1894.

MAGRUDER, G. M., passed assistant surgeon. To proceed to Key West Quarantine Station for duty. May 15, 1894.

KINYOUN, J. J., passed assistant surgeon. To proceed to Wilmington, Del., for special temporary duty. April 26, 1894. Detailed as chairman, Board for physical examination officers, Revenue Marine Service. April 30, 1894. Detailed to attend

annual meeting State Board of Health of North Carolina. May 11, 1894. To inspect property at Wilmington, N. C. May 14, 1894.

WOODWARD, R. M., passed assistant surgeon. To proceed to Chicago, Ill., for special duty. May 7, 1894.

VAUGHAN, G. T., passed assistant surgeon. Detailed as recorder, Board for physical examination officers, Revenue Marine Service. April 30, 1894.

STONER, J. B., passed assistant surgeon. To inspect quarantine ports. April 26, 1894.

PERRY, J. C., passed assistant surgeon. To assume command of service at Norfolk, Va. May 4, 1894.

YOUNG, G. B., assistant surgeon. To proceed to Key West, Fla., for duty. May 15, 1894.

BROWN, B. W., assistant surgeon. To proceed to Pittsburg, Pa., for duty. April 27, 1894.

ROSENAU, M. J., assistant surgeon. To proceed to Boston, Mass., for duty. April 23, 1894.

COFER, L. E., assistant surgeon. To proceed to San Diego, Cal., as inspector, and to assume command of the service after June 30th. April 26, 1894.

EAGER, J. M., assistant surgeon. To proceed to New Orleans, La., for duty. May 16, 1894.

NYDEGGER, J. A., assistant surgeon. To proceed to Savannah, Ga., for duty. April 28, 1894.

STRAYER, EDGAR, assistant surgeon. To report for duty on Revenue Bark "Chase." April 28, 1894.

OAKLEY, J. H., assistant surgeon. To rejoin station San Francisco, Cal. May 16, 1894.

PROMOTIONS.

G. B. YOUNG, assistant surgeon. Commissioned as passed assistant surgeon. May 25, 1894.

W. G. STIMPSON, assistant surgeon. Commissioned as passed assistant surgeon. May 25, 1894.

APPOINTMENTS.

ARTHUR B. THOMAS, of Illinois, commissioned as assistant surgeon. May 25, 1894.

HENRY W. WICKES, of Maryland, commissioned as assistant surgeon. May 25, 1894.

HUGH S. CUMMING, of Virginia, commissioned as assistant surgeon. May 25, 1894.

APPOINTMENT.

Governor Greenhalge has appointed MR. HENRY S. HOWE, of Brookline, Trustee of the Massachusetts General Hospital in place of MR. T. E. PROCTOR, resigned.

Address.

THE LEGISLATIVE CONTROL OF MEDICAL PRACTICE.¹

BY REGINALD H. FITZ, M.D., BOSTON.

(Continued from No. 24, p. 585.)

THE success of medical legislation in this country is now a matter of history; and it will be attempted to give a short sketch of what has been accomplished.

According to the researches of Dr. Joseph M. Toner,¹¹ the earliest legislation in the colonies relative to the practice of medicine was in Virginia in 1639. It appears that the charges of physicians and surgeons were so excessive

"that the hearts of divers masters were hardened rather to suffer their servants to perish for want of fit means and applications than by seeking relief to fall into the hands of griping and avaricious men; it be apprehended by such masters, who were more swayed by politick respects than Xian duty or charity, that it was the more painful and saving way to stand to the hazard of their servants than to entertain the certain charge of a physitian or chirurgern, whose demands for the most part exceed the purchase of the patient."¹²

A few years later this act was revised for the purpose of making a distinction between the charges of "surgeons, apothecaries, or such as have only served apprenticeship to those trades, who often prove very unskilful in the art of a physician"; and of those who have studied physic in any university and taken any degree therein.¹³

In 1649 Massachusetts passed a law forbidding "phisitians, chirurgians, midwives, or others," presuming "to exercise or putt forth any act contrary to the knowne rules of arte," or exercising "any force, violence or cruelty . . . no, not in the most difficult and desperate cases, — without the advice and consent of such as are skilful in the same arte, etc., etc."¹⁴ This law was also inserted in the Duke of York's laws enacted about 1665 for the government of the province of New York.

Dr. Toner's valuable article contains no evidence of further attempts at regulating the practice of medicine during the subsequent century. The number of carefully educated physicians was inconsiderable, quacks abounded, and of New York in 1753 it was stated: ¹⁵

"That place boasts the honor of above forty gentlemen of the faculty, and far the greatest part of them are mere pretenders to a profession of which they are entirely ignorant." . . .

"The war resulting in the conquest of Canada and subjugation of the French in 1763 created a demand for skilled medical officers and aided in the training of American students. Many of the English medical staff remained for several years in the vicinity of New York, establishing military hospitals and aroused the ambition of the colonial practitioners."¹⁶ . . .

"Although partial recognition of the profession and protection of the people had been secured in several of the colonies, and particularly in some of the larger cities, by legislation, the first well considered act regulating the prac-

tice of physics was that passed in New York, June 10, 1760, beginning as follows: 'Whereas many ignorant and unskilful persons in physick and surgery, in order to gain a subsistence, do take upon themselves to administer physick and practise surgery in the city of New York, to the endangering of the lives and limbs of their patients, and many poor and ignorant persons inhabiting the said city, who have been persuaded to become their patients, have been great sufferers thereby; for preventing such abuses for the future —

"1. *Be it enacted,*" etc."¹⁷

According to this act no person was allowed to practise, under a penalty of five pounds and costs, who had not previously passed an approved examination in physic and surgery before one of his Majesty's council, the Judges of the Supreme Court, the Attorney-General and the Mayor for the time being, or any three of them, taking to their assistance for such examination such person or persons as they in their discretion shall think fit.¹⁸

Twelve years later a similar act was passed in New Jersey at the instigation of the New Jersey Medical Society, and was the first comprehensive, protective law applied to a colony, the legislation above mentioned applying only to the city of New York. The examination was approved of and admitted by "any two of the judges of the supreme court, taking to their assistance for such examination such person or persons as they in their discretion shall think fit."¹⁹

In the following year, 1773, the code of Virginia required every surgeon, physician and dentist to take out a license, which authorized the holder to practise anywhere in the colony. Neglect to procure a license was punishable by a fine of not less than thirty nor more than one hundred dollars, nor could such negligent practitioners collect compensation for services.²⁰ In the same year, in Connecticut, a law for the suppression of mountebanks was enacted,²¹ although a year later the Lower House of Assembly in this colony negatived the memorial of Norwich physicians asking for the appointment of a committee legally authorized to examine and approve candidates if found qualified.²²

The War of the Revolution now occurred. Dr. Toner²³ thinks it probable that at this time

"there were not living in all the colonies 400 physicians who had received medical degrees; and yet, as is stated elsewhere, there were presumed to be over 3,500 practitioners."

According to the same authority,²⁴ the war gave

"great impetus and energy to the whole population of the colonies. The experience gained by the medical men who served in the army elevated their views, gave them confidence in the exercise of their professional duties, endeared them to the public, and made them almost oracles in the communities in which they resided. The spirit of gratitude also created friends for the profession in the various legislatures, led to the enactment of laws which were more just and protecting in their character, and popularized the more recent and thorough modes for the scientific study of medicine."

In 1783 New Jersey was the first of the States to pass a law regulating the practice of medicine. It was followed in 1792 by New York, which demanded of

practitioners in the city and county of New York two years of study with a reputable physician, if the candidate was a graduate of a college in the United States, otherwise three years of study. Also an examination before the Governor, Chancellor, Judges of the Supreme Court, Attorney-General, Mayor and Recorder of the city of New York, or any two of them who were to take to their assistance any three respectable practitioners with whom the examined person had not lived. The certificate of this board was a license to practise, and without it no legal demand could be made for services. Physicians who had regularly received the degree of Doctor of Medicine, those already in practice, and consulting physicians from neighboring States or counties were exempt from the provisions of this law. The above, somewhat modified, was made, in 1797, the general law of the State.²⁵

In 1798 power was given to the Medical and Chirurgical Faculty of Maryland to grant licenses "upon full examination or upon the production of diplomas from some respectable college." The penalty for practising without a license was \$50.00 for each offence.²⁶

During the first forty years of the present century, legislation, with a view to regulate the practice of medicine, was frequent and various. The initiative was taken by those desirous of protecting the people from ignorance, lack of skill and extortion; and the opposition came from quacks and pretenders of every kind.

New York, in 1806, incorporated medical societies for the purpose of regulating the practice of physic and surgery, following the example set by Massachusetts, and which proved so successful in that State after the amendments adopted by the Massachusetts Medical Society in 1804. In 1808, a few years after the territory of Orleans was set off from the Louisiana purchase, a bill was enacted by the territorial government, stating "that no person shall presume to practise medicine" without an examination, for which a diploma from some university or school was a qualification. This law was amended in 1816, and was enacted as the law for the State of Louisiana.²⁷

From this time on, State after State passed some form or other of a law for the prevention of quackery. And it is stated by Senn²⁸ that during the first half of our national existence every State had enacted such laws, with the exception of Pennsylvania, North Carolina and Virginia.

These laws, however, did not long remain operative; they were premature in many instances, there not being enough educated physicians to provide for the needs of the people. Quacks thus found their way into the remoter sections of the State, and their presence and assertions were welcomed by the sick and infirm. They practised in defiance of the law, whereas, now, unlicensed practitioners are declared exempt from the penalties of the law in States like Arizona and Idaho, when there is no licensed physician living within a convenient distance of the patient. Quackery spread from the remoter districts towards the centres of population, became more and more popular, and excited the more sympathy the more it was opposed. The difficulties in the way of enforcing the laws became greater. Juries refused to convict, officers of the

medical societies neglected to bring charges, and finally the laws were so amended as to exempt all quacks, mountebanks and charlatans from the penalties. This result attained, the laws became useless, and in certain States were effaced from the Statute Book.

The first serious blow to the regulation by the State of the practice of medicine was the result of the spread throughout the country of the doctrines of Samuel Thomson, who died in 1843. He was an illiterate farmer of New Hampshire, an empiric of the first water, but distinctly a remarkable man. He denounced the heroic treatment then in vogue by means of bleeding, mercurials and mineral medicines in general, and advocated the use of certain vegetable agents whose value he claimed to have discovered. He stated that he was in the habit of tasting herbs and roots, and was thus enabled to ascertain what were useful for any particular disease. In his "Narrative,"²⁹ first published in 1822, he announces as his general plan of treatment:

"to cleanse the stomach by giving No. 1, and produce as great an internal heat as I could by giving No. 2, and when necessary made use of steaming, in which I have always found great benefit, especially in fevers; after this I gave No. 3, to clear off the canker; and in all cases when the patient had not previously become so far reduced as to have nothing to build upon, I have been successful in restoring them to health."

No. 1 consisted of lobelia; No. 2 of red pepper; and No. 3 of a variety of herbs, including rosemary, bayberry, myrtle, sumac or raspberry, although he states that a great many other articles were "useful in removing canker."

In 1809, he was tried for the murder of one of his patients.³⁰

"As the learned Judge could find no law, common or statute, to punish the accused, he directed or advised those present to stop this quackery, as he called it, and for this purpose to petition the Legislature to make a law that should make it penal for all who should practice without license from some medical college to debar them of law to collect their debts; and if this should not answer, to make it penal by fine and imprisonment.

"This hint, thus given by the judge, was seized upon first in Massachusetts; from thence it has spread to nearly all the States of the Union. From this source may be traced all those unconstitutional laws which have been enacted in relation to this subject, and all those vexatious suits which I have had to attend in many of the States, from Massachusetts to South Carolina, more or less almost every year since. But I have been able to break them down by my patent being from higher authority, which Judge Parsons could not prevent, or perhaps he never thought of. He, however, made his own report, and handed it to the reporter, which is published in the sixth volume of Massachusetts Reports, and is resorted to by all the enemies of the practice for a defence against the system."

He afterwards brought suit against his principal accuser, Dr. French, which came to trial, again before Chief Justice Parsons, in 1811.³¹

"The judge then gave his charge to the jury, which was considered by those who heard it, to be the most prejudiced and partial one that they had ever heard. He made use of every means to raise the passions of the jury and turn them against me; stating that the defendant was completely justified in calling me a murderer, for if I was not guilty of wilful murder, it was barbarous, ignorant murder; and

³¹ Op. cit., p. 176.

even abused my lawyers for taking up of me, saying that they ought to be paid in screw augers and bull dogs."

The jury brought in a verdict for the defendant.

In 1813 he obtained a patent to secure to him the exclusive right of his system, and to put him above the reach of the law in any State. But in 1821 Judge Story decided that its specifications were improperly made out, and in 1823 a new patent was obtained.²²

"The preparing and compounding the foregoing vegetable medicines, in manner herein described, and the administering them to cure disease, as herein mentioned, together with the use of steam to produce perspiration, I claim as my own invention."

The simplicity of his theories of disease and of its treatment, the use of simples, always commending itself to the popular mind, and the notoriety attained by numerous lawsuits, all served to attract attention to Thomson's doctrines. Many editions of his writings were published, and agents were employed to travel throughout the States, selling with the book and medicines a family right to practise for \$20.00. "Friendly Botanic Societies" were established, the membership being composed of those who had purchased family rights, and the privileges in which are stated by him as follows:²³

"Every one who purchases a right for himself and family, becomes a member of the Friendly Botanic Society, and is entitled to all the privileges of a free intercourse with each other, and to converse with any one who has bought a right, for instruction and assistance."

Thomson's doctrines were especially favored in the eastern section of Massachusetts, and along the adjacent borders of Maine, New Hampshire and Vermont.

After the publication of his "Narrative" and the employment of agents, he and they travelled extensively in the South and West. Although they were unlicensed practitioners in most States, the laws had no penalties sufficient to prevent them from practising. His followers succeeded in securing the enactment of laws by which no person was to be debarred from using or applying for the benefit of the sick person any roots, barks or herbs, the growth or produce of the United States. At first the proviso was added, that they should be unable to recover by process of law any debt incurred from such practice. This objection was easily met by obtaining fees in advance. The restriction was of greater value to them for advertising purposes in creating sympathy, and we learn²⁴ that "thousands have had their sympathies enlisted in their behalf; have come to believe their senseless clamor, and had their prejudices aroused against the medical profession." Finally medical schools, called "eclectic," were established by those who were willing to take advantage of Thomson's success, adopting his practice, but avoiding his interference.

Thomsonianism prepared the way for the success of homœopathy, which proved to be the more effectual agent in annulling the licensing of physicians. In the words of Dr. J. W. Hamilton,²⁵ "It swaggered on the stage long enough to give a wholesome check to the excesses that brought it into being, and proved itself the bloodiest murderer that ever visited our too credulous community in the form of quackery."

In certain respects homœopathy bore a close resemblance

to Thomsonianism. It represented a reaction from the heroic treatment of the regular physicians; it offered a few remedies, although in palatable form, with such specific and authoritative directions that the family provided with pellet and pamphlet had but little need of the educated physician. Its leaders, however, came from the ranks of the latter, and its followers were to be found among the more intelligent, prosperous and influential members of society. Its adherents increased in numbers in the cities and larger towns, and it threw upon the opposition it encountered from members of the regular profession. Like Thomsonianism, it called for sympathy on the ground of intolerance, and persecution on the part of licensed physicians, and Thomsonianism and homœopathy combined succeeded in so emasculating existing laws regulating the practice of medicine that they became useless, and their removal from the statutes was often sought by all alike.

In 1838, Maryland made it lawful for every citizen of the State to charge and receive compensation for his services and medicines. In the following year, Georgia passed a revised medical act, in which it was "provided nothing be so construed as to operate against the Thomsonian or botanic practice or any other practitioners of medicine in this State."²⁶ A few years later, in 1847, it established a Botanico-medical board, with the same powers and duties as the regular board.²⁷ In New York, in 1844, a bill was enacted, of which Judge Beardsley said: "Since the passage of the act of 1844, quackery may certainly boast its triumphant establishment by law."²⁸

At the close of the first half of the present century there were practically no efficient laws controlling the practice of medicine by the licensing of physicians in this country. The history of such legislation in Massachusetts from the War of the Revolution to that of the Rebellion has been given elsewhere.²⁹ Existing laws had either been repealed or were not enforced, and the regularly educated physicians had ceased in their efforts to suppress quackery by attempting any legislative prohibitory enactments. They were largely responsible for this result. With the best of intentions throughout these fifty years, they failed to read aright the signs of the times, and by errors of omission and of commission they rather aided the progress of quackery than checked its growth.

With the incorporating of medical societies by the State, the licensing of physicians was placed in their hands. Examining boards were established and candidates were to appear before them. But in some States these boards were so few, and the members lived so far apart, that the examinations were not held. Such evasions of the law made it easy for a rejected candidate to obtain a special act of the legislature allowing him to practise. In case of rejection by one board he might appear before another less exacting. If all the boards in any one State were too stringent, it was possible for the candidate to obtain a license in another State, where the terms were less rigid, even by mere payment of the registration-fee. A license thus obtained was usually valid in other States. If he practised in violation of the law, it was the duty of no one to bring suit. Although the licensing power was transferred by the State to the medical societies, members

of the latter were unwilling to act as accusers and prosecutors from the demand it made upon them for time and money, and the necessity it placed them under of assuming a disagreeable and opprobrious task. Even if cases were brought to trial conviction was difficult, since the penalty was so severe that the jury was unwilling to condemn what it was told was essentially a difference of opinion.

What must be regarded as their chief mistake was the treatment of their homœopathic brethren. Irrespective of all questions of ethics it was a decided and decisive error of policy. The latter were educated physicians, certainly as honest as many of their associates, whatever may be said of their intelligence. Their expulsion and ostracism created two powerful opponents, largely representing two distinct classes of society, but united in their efforts to resist repression. The botanic, eclectic and physio-medical practitioners (the off-shoots and successors of Thomsonianism) and the homœopathists, as they increased in numbers and strength, were, combined, enabled to secure the repeal of all restrictive legislation. They became exempted by law from the need of a license, and the regular physician saw no necessity of paying the fee for a license which placed him in no different light before the public than the quack. As the irregulars formed chartered medical societies with the same privileges as those possessed by the regular societies, members of the latter in many States became active in securing the repeal of laws which proved of no value to the community. Eclectic and homœopathic medical schools were established, and the name of physician and the title of doctor of medicine no longer became of the least value in acquainting the public with any distinction between the educated practitioner and the ignorant pretender, and no check whatever was placed on the increase of the latter.

An interval of some twenty years now elapsed, during the first half of which the State medical societies were perfecting their organization with the view of maintaining a high standard of membership. A certain degree of uniformity in this action was the result of the formation of the American Medical Association in 1847. The annual meetings of this organization brought together representative men from the various State societies, most of whom had been actively interested in the legislative control of medical practice. They endeavored to improve the standard of medical education and the ethics of the regular profession throughout the country. The War of the Rebellion created a sudden and extensive demand for educated physicians and surgeons, their numbers speedily increased, and the subsequent rapid growth of the country has continued this increase. The brilliant progress in the various specialties of medicine made more apparent the distinction between the educated and skilful physician and the ignorant but pretentious quack. Homœopathic and eclectic medical schools were paying more attention to the instruction of their students, and the line was thus being more sharply drawn between practitioners of no training and those who had received some teaching. All educated physicians, whatever their degree of instruction, were interested in defending the community from mere pretenders, and their combination has led to the successful medical legislation of the past twenty-five years.

Since the law recognizes no distinction between regulars, homœopathists and eclectics, on the contrary, the

legislators have given like privileges to each, by incorporating them into medical societies and medical schools, it became obvious that if any legislation was to be secured against the worst forms of quackery, it must be obtained by the practical agreement of these incorporated medical bodies. The numerous experiments which have been made in the various States during the past twenty-five years, and which have led to the enactment of licensing laws in nearly all the States and Territories, have been the result of this harmony of action.⁴⁰ It has been justified not only by the needs of the community for protection, but also by the fact that both homœopathists and eclectics represent a kind of practitioner whose education is constantly improving. Homœopathists, in particular, have been, from the beginning, physicians of a certain, and at times of a considerable degree of education. They are honestly and earnestly endeavoring to improve their educational facilities, and some of the eclectic schools are following in their footsteps.

In 1872, a bill was prepared under the auspices of the New York Medico-Legal Society, and was favorably acted upon by the legislature, but was subsequently vetoed by the governor.⁴¹ This unsuccessful attempt was followed in 1873 by the passage of a law in Texas, requiring the registration of diplomas by all practitioners entering the State. It was repealed and replaced in 1876 by an act establishing boards of examiners, who were to examine all applicants for certificates of qualification without preference to any school of medicine. This law, to-day, in the words of Dr. West of Galveston, "is practically inoperative, as but few boards are organized, and about most that any of them do is to license non-graduates."

In the District of Columbia in 1874 it was the duty of every physician to register at the office of the board of health, under penalty of from \$25.00 to \$200.00. This regulation was legalized by Congress in 1880. All physicians required to register must do so upon a license from some chartered medical society, or upon a diploma from some medical school or institution.

The law of Nevada, enacted in 1875, makes a law practitioner one who has received a medical education and a diploma from some regularly chartered school having a *bona fide* existence when the diploma was granted. The county recorder accepts the diploma.

In 1877 a law was passed in Alabama according to which a license or diploma, or certificate of qualification, was essential to the lawful practitioner. If he wished to practise any irregular system, he was obliged to pass an examination in anatomy, physiology, chemistry and the mechanism of labor before the Censors of the Medical Association of the State of Alabama, or of some affiliated County Medical Society. This act was replaced by that of 1887, which was amended in 1891, and according to Dr. Cochran of the Board of Censors is

"almost ideally perfect. If the State would invite us to change it according to our wishes, we would not know what change to suggest. All we have to ask of the State is

⁴⁰ For much of the information relative to the provisions of the laws in the various States and Territories, I am indebted to the admirable Synopsis of the existing Statutes, prepared by William A. Poste, late deputy attorney-general of the State of New York, and Charles A. Boston, Esq., of the New York City Bar, for the text-book of Medical Jurisprudence, Forensic Medicine and Toxicology, of Witthaus and Becker, just published. By the aid of our librarian, Dr. E. H. Brigham, I have been enabled to obtain from the respective officials of many of the States copies of the medical licensing laws of these States, and take this opportunity of expressing my thanks to all concerned.

⁴¹ New York Med. Journal, 1874, xx, 64.

simply to let our law stand as it is and enforce it in the courts. . . . We have a very few homœopathic practitioners in Alabama, but a considerable number of doctors who, graduated in eclectic schools, have availed themselves of the advantages we have to offer them, and have become good working members of our organization."⁴⁸

In the same year Illinois passed its first law, which was amended in 1887. It is unnecessary to enter into the details of medical legislation during the next fourteen years. It is merely to be stated that laws were passed as follows:

<i>Year.</i>	<i>State or Territory.</i>
1880	Vermont.
1882	Georgia, Rhode Island.
1883	Maine, Michigan, North Carolina.
1884	New Mexico.
1885	Indiana.
1886	Iowa.
1887	California, Idaho, Minnesota, Virginia, Wisconsin, Wyoming.
1888	Tennessee.
1889	Delaware, Kansas, Missouri, Montana, Oregon.
1890	New Jersey, North Dakota, Ohio, South Carolina, Washington.
1891	Colorado, Nebraska, West Virginia.
1892	Florida, Maryland, Mississippi, Utah.
1893	Arkansas, Arizona, Connecticut, Kentucky, New York, Oklahoma, Pennsylvania, South Dakota.

THE FREQUENCY OF RENAL ALBUMINURIA, AS SHOWN BY ALBUMIN AND CASTS, APART FROM BRIGHT'S DISEASE, FEVER, OR OBVIOUS CAUSE OF RENAL IRRITATION.¹

BY FREDERICK C. SHATTUCK, M.D., OF BOSTON.

IN no branch of human activity, perhaps, can more striking illustrations be found of the dangers of hasty conclusions from insufficient data than in medicine. This is no reflection on our calling. It naturally flows from the fact that our knowledge of many things is still very imperfect, while the demands for the practical application of our knowledge are constant and imperative. The sick man wants instant help, and cannot wait while doubtful points are being settled. Medicine is more than an art, less, in a sense, than an exact science. The clinical significance of albumin and casts affords one of these illustrations. The chemical preceded the microscopical examination of the urine, and the latter first made it possible to determine with any accuracy the portion of the urinary tract from which the albumin is derived. The presence of casts shows that the true renal tissue is involved, and was for some time held to be diagnostic of Bright's disease. I well remember the grave prognosis which the discovery of albumin and casts was thought to necessitate when I was a hospital interne, not much more than twenty years ago. Perhaps I incorrectly interpreted my teaching — students sometimes do — but I think this was at that time generally regarded by the profession as damning evidence. Albumin and casts meant Bright's disease, and that meant an in-

evitably and more or less rapidly fatal disease. Further experience and the irresistible logic of facts has led to such changes in these views that considerable discussion has been held as to whether albuminuria might not be physiological, so common is it found to be, so little bearing may it have on the vigor or longevity of its possessor. Into this discussion I do not propose really to enter. Absolute physical perfection is occasionally found in the human being; but the ideal and the real are nearly as sharply contrasted in the more purely bodily as in the moral qualities. Whether there be a physiological albuminuria is largely a matter of definition of the word physiological.

Much ingenuity has been devoted to the discovery and application of tests of extreme delicacy for albumin. My friend and colleague, E. S. Wood, assures me that for clinical and qualitative purposes none of these tests can compare with the old heat and nitric acid tests; and I am glad to see similar views expressed very recently by D. D. Stewart,² of Philadelphia. These are the tests used in the cases which I have analyzed. A cloudiness of the boiled upper layer of urine in the test-tube after the addition of acetic acid, and the opaque zone with nitric acid are therefore considered proof positive of the presence of albumin, as a negative result is proof of its absence. To my eye the heat test is the more delicate of the two, but I know that all do not find it so. Vaunderpoel,³ in a recent paper on albuminuria without manifest organic renal lesion, has collected the literature of the subject and justly calls attention to the discrepancy which exists between the percentages of different observers examining considerable numbers of presumably healthy persons. Chateaubourg finds albuminuria in 84 per cent. of 701 examined; Grainger Stewart in 31 per cent. of 407 examined. Others put the percentage still lower, but even this discrepancy is sufficient to show that something is the matter. Doubtless Millard is right in believing that Chateaubourg, who used Tanret's test in many of his examinations, mistook mucin or some other non-albuminous organic substance for albumin. As far as I know casts have not been looked for as carefully as albumin. The search for them demands a good deal of time if the sediment is scanty; and they may easily be overlooked when present if ample time is not allowed the urine to settle, and if skill in the selection of portions of the sediment is not exercised. Experience has led me to be skeptical when the statement is made to me that a distinct trace of albumin is present, but that casts as well as other formed elements, such as blood and pus, are absent. In such cases I have repeatedly found that more careful examination revealed the casts.

These bodies still enjoy a worse reputation in the minds of the laity than albumin, as well as in the minds of the profession in general. Patients are alarmed by the knowledge that there are casts in their urine, much as they used to be by hearing that they had a murmur in their hearts.

For five or six years now I have been more and more particular to have a thorough examination of the urines of patients seeking my advice made by competent men, quite irrespective of the nature of the complaint which brought the patient. The frequency with which albumin and casts, chiefly hyaline and finely granular of small diameter, was reported in

¹ Paper read at the Ninth Annual Meeting of the Association of American Physicians, Washington, D. C., Thursday, May 31, 1894.

³ Medical Record, November 11, 1893.

those at or beyond middle life entirely apart from any other evidence of renal mischief, attracted my attention. This led to the preservation of the reports of those of fifty years of age or more, and more recently also of the younger patients. Consequently I deal with larger figures relatively or absolutely at the later ages. I now regret that I did not begin my collection on a more comprehensive basis. All the same, it does not seem probable that the result would be very materially modified. In the decade of twenty to thirty I believe that a larger number of cases would reduce the percentage of those with renal albuminuria, and I think also that larger figures would show the condition to be quite as frequent between eighty and ninety as between seventy and eighty; but I cannot regard these sources of error as serious.

In the collection of these cases I have excluded all those with fever; all in which such well-known renal irritants as bile and sugar were present, no matter how small in amount; and also those in which examination rendered it probable that the mechanical effect of crystalline formation in the kidneys was directly responsible for the albumin and casts.

In the division of cases reported as showing albumin and no casts, no cases are included in which there was sufficient blood or pus, either from the vagina or lower urinary passages, to account for the reaction. In many of these I am convinced that more careful search would have revealed casts. Cases of cardiac and other organic disease are included, but I have tried to omit all those in which passive congestion could account for the findings. Of course, all cases of unquestioned Bright's disease are excluded. In short, the attempt has been made to determine approximately how frequently renal albuminuria and casts are encountered in the urine in the ordinary run of adults who consult a doctor, but present no evidence outside of the urine of primary or secondary renal disease. Some sixty of the patients were hospital cases, partly medical, partly surgical, suffering from widely varying maladies or injuries. No record has been kept as to the time at which the urines of my cases were voided. The larger number probably were passed on rising in the morning; many were passed at mid-day in my office; some both morning and evening; not a few were mixed specimens of the twenty-four hours.

TABLE.

Age.	No. of Cases.	Albumin and Casts.	Albumin and no Casts.	No Albumin or Casts.
20-30	25	8, or 32%	3, or 12%	14, or 56%
30-40	39	9, or 23%	4, or 10%	26, or 66%
40-50	47	26, or 55%	3, or 6%	18, or 38%
50-60	99	64, or 65%	11, or 11%	24, or 24%
60-70	57	42, or 74%	5, or 9%	10, or 17%
70-80	16	16, or 100%	00	00
80-90	14	11, or 79%	00	3, or 21%

The personal equation can be eliminated from my results for the reason that the examination was made in, roughly speaking, nearly equal proportion by four different observers, and a few by two others, all competent to distinguish mucous from renal casts. The small percentage of cases in which albumin was found without casts shows, I think, that no serious suspicion

can attach to my results on the ground that other substances were often mistaken for albumin. In the great majority of cases but a single examination was made, but in a fair number there were two or more.

The table needs little explanation. It shows that the percentage of urines containing albumin and casts rises steadily with each decade from the fourth to the eighth, while those free from albumin and casts are in steadily decreasing percentage, and the proportion of those containing albumin but no casts remains nearly the same throughout. The number of cases in which casts were found without albumin was so small that these have not been classified.

The question remains as to the significance of these results. The pathological meaning is not easy of absolute proof. The class of patients who form the basis of my statistics are slow to die, and office and hospital patients are easily lost sight of. A considerable number of the patients I know to be alive, and apparently as well as when albumin and casts were discovered a number of years ago. In only two have I notes of autopsies. In one patient of eighty-five death was the result mainly of old age, and the kidneys were exceptionally healthy to the naked eye. In another of eighty-six years death was due to sudden uræmia supervening on prostatic enlargement necessitating repeated catheterization, cystitis, and impacted calculus at the vesical end of the left ureter; the kidneys were cystic and atrophic, especially in the cortices. Albumin and casts were found four years before death, and yet the general health was remarkably good for a person of upwards of eighty. In some of the cases albumin and casts were undoubtedly due to active hyperæmia or to irritation of the kidneys, and was perhaps transitory; but it is my belief that the facts in my table are best explained on the theory that the albumin and casts are the expression of senile renal atrophy, especially as far as the higher decades go.

There is no internal organ in which it lies in our power to detect so unerringly minute and slight changes as in the kidney. The heart, lungs, and blood-vessels as a whole are far less accessible to our examination. Age is not a matter of years, nor do we grow old symmetrically. I see no other reasonable explanation for the progressive increase in the frequency of albumin and casts as age advances. Whether this pathological doctrine be true or not the clinical significance admits, to my mind at least, of no doubtful interpretation. My anxiety is not awakened either for the present or the future by the report that a faint trace of albumin and hyaline and finely granular casts of small diameter are found in the urine of a patient after the age of fifty, provided that the kidneys are doing sufficient work as is shown by the twenty-four-hour excretion of solids, and provided that there are no symptoms.

Three years ago I was consulted by two brothers, fifty-two and fifty-five years of age, who had been urgently solicited to take out life insurance policies for one hundred thousand dollars each. But the ardor of the company was cooled when it was found that their urines contained a slight trace of albumin and casts, and their anxieties were awakened. Albumin and casts were constantly found in several examinations during the succeeding year; but the men were and remain perfectly well. The urines were rather concentrated. In patients under fifty albumin and

casts do not disturb me anything like as much as they did formerly. The important practical point is that they are not necessarily the precursors of serious kidney disease, and that their presence does not inevitably demand very careful regulation of the life and constant medical supervision.

In a certain proportion of cases, how large this proportion may be it will take years to determine, interstitial changes will reach a degree to shorten life, advancing more or less rapidly. It is not in our power at present to distinguish accurately which these cases are. Some help is afforded by the close estimation of solids in the twenty-four-hour urine; but in the average individual the reserve balance of kidney power is sufficient to permit of extensive renal impairment without curtailment of the ordinary daily work. The reserve may be diminished or gone; but if the reserve is not drawn upon too much or at all no apparent stringency is felt. We can grant that renal albuminuria is always pathological. Chronic pharyngitis is also pathological. It may be heresy, but I cannot resist the feeling that we are coming to believe that the clinical significance of the one is not necessarily greater than that of the other. I shall follow up my cases as far as I can and hope to be able in the course of years to throw further light on this important practical question. Life insurance companies are right in refusing risks reported as presenting albumin and casts. Life insurance is more like the French than the English criminal law; — it holds that innocence must be proved beyond reasonable doubt. But I have no doubt that risks are daily accepted by the best companies where an expert examination would detect albumin and casts. Few examiners apply the heat and nitric acid tests in a manner to try their full delicacy, and a microscopical examination is practically not demanded. Even if it were it would not ordinarily be sufficiently careful to be of much value.

Finally, my results may be summed up in the following conclusions:

(1) Renal albuminuria, as proved by the presence of both albumin and casts, is much more common in adults quite apart from Bright's disease or any obvious source of renal irritation than is generally supposed.

(2) The frequency increases steadily and progressively with advancing age.

(3) This increase with age suggests the explanation that the albuminuria is often an indication of senile degeneration.

(4) Though it cannot be regarded as yet as absolutely proved, it is highly probable that faint traces of albumin and hyaline and finely granular casts of small diameter are often, especially in those past fifty years of age, of little or no practical importance.

PELVIC INFLAMMATIONS.¹

BY LEONARD WHEELER, M.D., WORCESTER, MASS.

THE subject of Pelvic Inflammation is one of great importance to every practitioner; for the condition is very common, and, for two reasons beyond inherent difficulties, it is not easy to diagnose. These two reasons for the difficulty in diagnosis are, first, that in its present aspect the subject is so novel that only the younger men among us learned anything of it in the

medical school; second, that any degree of expertness in diagnosis requires the handling of a good many cases.

The pathological history of pelvic inflammations has been long and varied, but the salient points are interesting, and may be made very brief. Up to 1850 there was nothing extraordinary. Correct post-mortem observations had been made and recorded. Forty years ago, however, Nouat in France, followed by West and Simpson in Great Britain, and they again by Emmet in this country (of course, there are other names in plenty, but these were leaders), placed the seat of all these pelvic indurations and suppurations in the cellular tissue of the pelvis. It is wrong to say that these men based their ideas unduly on what they were able to feel during life, on clinical appearances and signs rather than the revelations of the post-mortem table. Autopsies do give strong credence to this view. It is only abdominal surgery, after all, that has proved it false. Where the pelvic inflammation has gone on to a fatal result, this cellular tissue has become extensively involved, and it is quite impossible to determine the point of origin of the disease. The suppurative process gets into this cellular area and follows it along, just as Schlesinger's air and liquid glue followed it between the folds of the broad ligament, along the psoas muscles, inward around the cervix, outward to the inguinal ring and downward between vagina and rectum. Having felt the disease during life and in its earlier stages apparently in the broad ligament, and after death finding a vast suppuration involving this very cellular area, it was natural enough to conclude that the disease had been all the time an affection of the cellular tissue, and that the diseased tubes always found with it were secondary. All this time, however, the opposite and correct view was stoutly maintained by Aran and his followers. He insisted that the masses felt during life were the same as those found so often after death from other causes as well as this pelvic inflammation, namely, diseased Fallopian tubes.

In 1857 appeared the first account of Bernutz's remarkable researches on the nature and pathology of pelvic inflammations. He clearly described the disease clinically; and he showed pathologically that it was a disease of the tubes and ovaries accompanied by peritonitis, and that cellulitis had no influence in causing the symptoms, that, in fact, it rarely existed at all as a primary disease except as a phlegmon in puerperal cases. This is the accepted doctrine of to day, in the past few years made plain by hundreds of operations for the radical cure of that large class of cases until recently regarded and treated as chronic cellulitis.

Notwithstanding this thorough work and its thorough discussion for years, the opposite theory still had its supporters, and would have had to the present day but for the revelation of Tait's operation, so-called.

In 1872 Battey did his first oöphorectomy, and the discussion and operations following prepared men's minds for the favorable reception of Tait's operation. Tait may have done some operations before, but the table in his book "Diseases of Women" begins with 1880. The operation for removal of diseased appendages was not done in this country until 1882. In 1883 it began to be much talked about, and has been ever since. The more it was discussed, the more attention was diverted from cellular tissue and fastened upon Fallopian tubes, though men were slow of conversion. Emmet held his ground firmly until 1888 or 1889.

It seems strange that so common and so grave a dis-

¹ Read before the Worcester Society for Medical Improvement, April 4, 1894.

ease as salpingitis should have been neglected for so long a time, especially after it had been so well described as it was by Bernutz. Still there would probably have been no further advance in these times except that Lister's grand discovery and proof of the value of cleanliness in surgery had made modern abdominal work possible. Except for this the pioneer work of Battey, Hegar, and Tait would have been quite likely to be dropped and forgotten.

With the advance in pathological knowledge and surgical treatment has come an eager study of the causes producing these inflammations, and all this attention has resulted in finding the disease of far more frequent occurrence than had been supposed. Gonorrhœa in the female has received a new meaning, and the necessity of surgical cleanliness in all gynecological and obstetrical work has received a capital emphasis.

In 1875 Noeggerath first published in this country his ideas in regard to latent gonorrhœa, which have given rise to a vast amount of discussion. It was a saying of Ricord that in the great conflagration of the final judgment the last thing to be consumed would be a drop of gleet. Noeggerath's ideas were in the same line. He maintained that any stricture after a gonorrhœa supplied a secretion capable of infecting the female, and that the favorite chronic abiding place of this inflammation in the female was in the tubes. His views have not been proved, but they went far in bringing about the modern idea of gonorrhœal disease in women. It used until quite recently to be considered a trivial disease. But with the present better knowledge of tubal pathology it becomes plain that it may be a very serious and dangerous disease.

It seems to be proved that some, perhaps many, deaths ascribed to puerperal fever are really cases of ruptured gonorrhœal pyosalpinx.

Another and probably more important cause than even gonorrhœa is the septic inflammation that extends over the genital mucous membranes after an unclean confinement, or especially abortion, or after the use of unclean instruments obstetrically or gynecologically.

There are other causes like syphilis, tuberculosis, exanthematic fevers, tubal pregnancy; but the important truth is that pelvic cellulitis, as it used to be understood, practically does not exist. The hard vaginal vault, the pre-uterine masses, the lumps by the side of or behind the uterus, the thickenings, the indurations, the areas of fulness with which we are so familiar, all these come from diseased tubes and consist either of swollen and adherent tubes and ovaries, or of peritoneal adhesions, or cicatricial bands. Other masses, of course, are often enough felt in the pelvis, but practically all the cases which used to be considered cellulitis are of this sort, and they are caused by an extension of inflammation from the uterine mucous membranes into the tubes.

Having in mind the bacterial nature of the disease its etiology may be expressed as follows: pus in the pelvis may owe its origin, first, to an inflammation of one sort or another (that is, may be owing to some form or another of germ growth) extending over the uterine mucous membrane into or through Fallopian tubes (gonococcus, etc.); second, to an inflammation extending through the parenchyma of the uterus via lymphatics or veins (streptococcus, etc.); third, to an inflammation derived from the intestine—the appendix, in one of my cases (*bacillus coli communis*).

In the great majority of cases it comes in the first way, via utero-tubal mucosa. It is a pyo-salpinx or the sequelæ of a pyo-salpinx. Those occurring in the second way, by an infection through the lymphatic or venous channel of the uterus, are of septic origin, starting from an abortion, confinement, or some surgical operation on the genital organs. The third sort is rare.

The prognosis and treatment of these cases of pelvic inflammation is a matter of much perplexity, and each case has to be decided on its own merits. One would think that a consultation of the authors writing just before the surgical treatment of the disease began, would give a definite idea of the prognosis of the disease. As a matter of fact, however, one finds merely vague statements of personal impressions, the general idea being that pelvic inflammation, except in puerperal cases, is not often fatal but is apt to entail a vast amount of distressing sequelæ. Wherever figures are used, however, the mortality becomes more conspicuous, as in McClintock's twenty-four cases with seven deaths.

The comparison is often made between salpingitis and appendicitis, but the two cases are only distantly similar. The appendix is a useless organ, and it is an advantage to be rid of even a healthy one, whereas there is no more important organ, except those necessary to life, than the Fallopian tube. Again, the diseased tube more frequently drains successfully into the uterus than the appendix into the cæcum. The universal surgical treatment of appendicitis may be maintained with some show of reason. Not so with salpingitis. Men make very definite statements as to certain conditions of the tubes entailing sterility, but it is a matter of much difficulty to determine what tubes are hopelessly diseased. I have seen a chronic pelvic inflammation, many months in duration, where the pelvis from side to side was of wooden hardness, in a woman who afterwards bore several children. Diseased appendages are not to be indiscriminately removed.

The cases to be operated upon are those where there is a recurrence of disease arising from a permanent focus of disease; second, those where there is a permanently palpable enlargement of the tube causing symptoms which wear upon the health; third, a few acute cases which have to be treated simply as abscesses.

As an illustration of my subject I have briefly reported the following ten cases, all but one of which occurred in my last year's service at Memorial Hospital. Four recovered without operation, two after the removal of the appendages, one after vaginal drainage, one died of peritonitis after operation, and one (a puerperal case) of peritonitis without operation.

CASE I. D. W., admitted October 28, 1892. Thirty-eight years old; widow; three children, youngest thirteen years. History of salpingitis one year before entrance. Recurrent attack two weeks before entrance. Whole pelvis found filled with hard irregular, sensitive mass, in which no organs could be made out. In three months this had gradually disappeared until there was nothing abnormal beyond slight lateral thickenings with backward displacement of the uterus. Patient was feeling well and having no pain even at time of menstruation.

CASE II. E. D., thirty-six years old, married. Admitted to Memorial Hospital November 24, 1892.

No children. Abortion four months before admission, followed by pelvic inflammation. Probable abortion five weeks before admission, followed again by pelvic inflammation. On admission there was a hard, tender mass extending from the retroflexed uterus to left pelvic wall. Under treatment this mass slowly disappeared, leaving an adherent retroflexed uterus; and patient had pretty well recovered her health in ten weeks.

CASE III. J. S., twenty-two years old, single. Admitted to Memorial Hospital February 16, 1893, with appendicitis. Abscess opened and drained (pus two ounces) February 17th. Limits of abscess cavity could be touched by finger in all directions except toward pelvis. This wound was completely closed by March 23d. Two weeks before this a purulent vaginal discharge led to the discovery of a double salpingitis, which gradually disappeared under treatment in the course of two months, leaving nothing palpably wrong in the pelvis except a retroflexion with adhesions.

CASE IV. J. McS., twenty-two years, single. Admitted to Memorial Hospital January 10, 1893. Confined with first child in Canada two weeks before entrance. Placenta adherent and removed. Chill on seventh day with abdominal pain and tenderness, vomiting and diarrhoea. Acute symptoms abated; but patient lost flesh, color and appetite, and complained of nearly constant pain up to time of entrance. Examined at this time, pulse was 95, temperature 101°. Abdomen somewhat distended and tender. P. V. uterus crowded backward and to the right by a hard, tender, immovable mass, filling left side of pelvis and extending above pelvis brim. After six weeks in the hospital, the mass had entirely disappeared, and the uterus was normally movable.

CASE V. L. R., twenty-one years, single. Admitted to Memorial Hospital January 20, 1893. A thin, pale, nervous girl. Gives history of invalidism, amenorrhoea, polyuria, etc., for four years. Has had local treatment. On left of uterus is a pear-shaped mass, twice as large as uterus, closely juxtaposed but not adherent to that organ. The diagnosis was solid tumor of ovary. The abdomen was opened February 15th. The tumor proved to be a huge pyosalpinx larger than the fist, with a few light adhesions to floor of pelvis and one very firm attachment at utero-vaginal junction, where the pus was apparently creeping toward the vagina. The breaking of this adhesion allowed a single drop of pus to escape. The tumor was easily tied off and removed. The right tube was found enlarged into half the size of this, and filled with pus. This was also removed. The recovery was uneventful. Discharged well March 14th.

CASE VI. B. W., twenty-five years, single. Entered Memorial Hospital November 22, 1893. Suffering from acute gonorrhoeal salpingitis (gonococci found in vaginal discharge). Pain was very severe, and patient altogether very sick. The acute symptoms passed away in the course of a few weeks, and she began to improve decidedly. The pelvic organs became less matted, and it was possible to distinguish the uterus with the swollen tubes on either side. At this point improvement ceased, pain became worse, and we decided to remove the tubes. This was done January 26th. The tubes were perhaps double the size of the thumb, and tensely filled with thin pus. As always in these cases, they were folded downward and back-

ward under the broad ligament. Adhesions were strong and universal. At first, it seemed impossible to find any place of cleavage. By patient scratching they were dug out, tied off without the loss of any pus. Was allowed to sit up in two weeks. Discharged well March 2d.

CASE VII. J. E., twenty-five years, married. Entered Memorial Hospital March 2, 1893. Artificial abortion a year ago followed by severe hæmorrhage. Confined at term six weeks ago. Had chill and fever on second day, otherwise recovery was not interrupted. Yesterday, March 1st, was seized with severe pain in pelvis accompanied by nausea and vomiting. Entered hospital March 2d at 5 P. M., temperature 104.4°, pulse 120. No defecation for two days; no urine for thirty hours, 22 ounces drawn by catheter. Abdomen moderately distended and tender. Masses on both sides of uterus felt by vagina. Uterus much enlarged. Free catharsis caused improvement in symptoms. Patient was so severely sick that hesitation was felt about opening the abdomen, so an opening was made per vaginam, drawing off four ounces of pus, and a drainage-tube inserted. The cavity was washed out daily, discharging pus for two weeks. Patient slowly improved, and was discharged after six weeks in hospital feeling nearly well. Uterus was still too large; adherent to it on the left was a mass the size of an English walnut. The right adnexa were naturally soft.

CASE VIII. N. M., thirty-one years, married. Entered Memorial Hospital March 12, 1893. Patient had a history which led to a probable diagnosis of tubercular peritonitis. Laparotomy was done. No tubercles found, but the whole pelvis was found occupied by what appeared to be a soft, solid mass, easily bleeding, in which pelvic organs, omentum and intestines were hopelessly involved. The next day began a discharge of pus from the rectum, which continued several days and was estimated at about a pint in amount. She improved rapidly; the pelvic mass melted down to an insignificant thickening; and she was discharged well on April 16th.

CASE IX. M. C., twenty-eight years, married. Entered Memorial Hospital February 14, 1893. Married at eighteen; child one year later. Three years ago had inflammation of the bowels. In bed four weeks. Unable to do full work for a year, and has been subject to pelvic pain since. December period copious, followed by recurrence of inflammation. In bed since. January, flow scanty, and followed by purulent vaginal discharge, which has continued since. Patient is thin, pale, with little appetite, small pulse, temperature nearly normal. Hard mass felt by palpation above pubes. Uterus in nearly normal position, partially embedded in hard mass on right, which extends from pelvic wall to beyond median line. Mass is hard, immovable, not sensitive. Orifice of sinus from which the pus comes, felt behind cervix to right. It was found impossible to follow this sinus for the purpose of dilatation. It was thought better to attack the trouble through the abdominal wall.

At the operation on March 28th, the right tube was found divided into two distinct four-ounce cavities filled with pus, extending from the side of the uterus to the cæcum and universally adherent. Omentum could not be separated, and was tied off. When the tube was nearly enucleated, it burst and covered the field of operation with pus. This was washed out with hot water, the enucleation completed, and the tumor tied off. There

was no difficulty of separation at the point of the fistulous opening into the vagina. Left tube healthy. Large gauze drain was left in. Patient died of peritonitis at the end of the third day.

CASE X. R. E., forty years, married. Admitted to Memorial Hospital March 15, 1893. First child born three weeks before entrance. Confinement normal. Was up feeling quite well on the eighth day, March 10th. Five days before entrance, eighteen days after confinement, after exposure, wetting feet, etc., had a chill followed by fever, vomiting, abdominal pain and tenderness. On 13th, temperature 103°, pulse 130. On 15th, when she entered hospital, temperature 103°, pulse 100. Abdomen moderately distended and tender; countenance dull. Said she felt better than the day before. Nothing abnormal was felt by the vagina. A few hours later she grew rapidly worse. At evening, temperature was 105°, pulse 170; and she died at 4 A. M., March 16th. Autopsy five or six hours after death. Body warm. Rigor mortis not present. When abdominal cavity was opened, a sero-purulent fluid escaped. The amount of this fluid in abdominal cavity estimated at from six to eight ounces. Peritoneum everywhere covered with lymph flakes. Intestinal coils just beginning to adhere one to another. Signs of peritonitis as much marked in upper part of abdomen as lower. Vermiform appendix and gall-bladder normal. Uterus possibly a trifle subinvolved. Site of placenta evident upon posterior part of fundus. Fallopian tubes and broad ligament free from adhesions. Broad ligament not thickened. Cause of the general peritonitis not determined by the post-mortem appearances.

Reports of Societies.

ASSOCIATION OF AMERICAN PHYSICIANS.

NINTH ANNUAL MEETING, WASHINGTON, D. C., MAY 29, 30, 31 AND JUNE 1, 1894.

FIRST DAY.—TUESDAY.

PRESIDENT REGINALD H. FITZ, of Boston, called the Association to order, and delivered an address on the

RISE AND FALL OF THE LICENSED PHYSICIAN IN MASSACHUSETTS, 1781-1860.¹

DR. BEVERLY ROBINSON, of New York, read a paper on

THE TREATMENT OF CERTAIN SYMPTOMS OF GROUP-PNEUMONIA, PARTICULARLY IN ADULTS.

The treatment of pyrexia and pulmonary congestion, he said, are of special interest in the first stage. The modern antipyretic drugs are not ordinarily useful, although good, occasionally. Phenacetine is the most satisfactory. More reliance is placed upon the use of spirits of Mindererus, citrate of potash and sulphate of magnesia to reduce temperature by action on the skin, kidneys and bowels. Three to five grains of quinine every four to six hours tends to diminish fever while strengthening somewhat the heart. Cold sponging, the ice coil, cold pack or cool bath for the purpose of reducing temperature do not act with any special efficacy as usually employed. Occasionally, when the

temperature is beyond 104° and there are evidences of adynamia, the tub-bath at 80° to 90° F. may be usefully employed, combined with continuous friction.

Aconite or aconitin may often be injurious by diminishing the energy of cardiac contraction. Even when combined in its use with digitalin, or digitalin and strychnine, it is not free at times from grave objections. There are other drugs eminently more useful, both theoretically and practically. In this stage of pneumonia no drug acts as well as antimony in small repeated doses. Kermes mineral, or the oxysulphuret of antimony, is the best form. It is given usually in doses of $\frac{1}{2}$ of a grain every two hours, or every hour for a while, in a mixture with syrup of gum and orange-flower water. Employed in this manner, fever and pulmonary congestion diminish at times in a very obvious manner. Expectoration becomes easier and more abundant, and the sputa from being very tenacious and viscid are more fluid and brought up with relative ease and increased frequency. Kermes mineral given in this way is not irritating to the digestive tract as tartar emetic often is, and does not produce a collapsed condition. It suits children, also, remarkably well. To aid its advantageous effect, we should employ at times alcohol internally, and revulsives to the chest wall. The great mistake formerly made in the use of antimony was the employment of the wrong salt and its use in excessive doses.

When the heart is particularly taxed by reason of pulmonary congestion and a tendency to cedema, no drug produces the rapid and remarkable results of nitroglycerin given by the mouth, or better still, hypodermically. We must not rigidly adhere to the ordinary dose of $\frac{1}{100}$ grain, but should use $\frac{1}{60}$ or $\frac{1}{30}$ if the condition of the patient is imminently threatening.

The use of inhalations of oxygen in relieving pulmonary congestion affords marked temporary relief to breathing in the greater number of cases of pneumonia; but, in a few instances, not even relief is afforded, but the dyspnoea, and subjective distress is obviously increased. These differences of action cannot always be accounted for.

It is essential to have pneumonia patients drink abundantly of water, and not force them simply to take milk, beef-tea, or broths of different kinds, with the idea that all that is required is to give nutritious fluids, losing sight of the great importance of water given by the stomach to promote the elimination of poisonous excreta through the skin and kidneys. The abundant use of cold spring-water or soda-water gives relief to thirst and helps reduce the fever, and may diminish slightly the viscosity of the expectoration.

The proper use of alcohol in the treatment of pneumonia is a difficult problem. Unquestionably, in many instances it is very beneficial. It is generally judicious practice when any reasonable doubt prevails as to the condition of the patient with respect to any one of the numerous conditions which seem threatening to life, to give moderate and repeated doses of alcohol. There are two absolute contra-indications: first, cases in which the patient is highly plethoric; second, cases in which the hepatic engorgement and gastric catarrh render it pernicious because nausea and stomachal intolerance are increased by its exhibition even in moderate amount, and assimilation of food and water is prevented.

The use of calomel in small repeated doses often has marked beneficial effect in cases where the tongue

¹ See page 529 of the Journal.

remains yellow and thickly coated with fur, while the breath is offensive. An engorged and sometimes tender liver, a hard and distended abdomen, are frequently dissipated by this medication.

The two dangers most to be feared in the state of hepatization as well as that of crisis, come from heart-failure or pulmonary hyperæmia. How are these conditions to be met? The author's convictions are opposed to the use of digitalis or digitalin, except in very small doses, and then only to control cardiac irregularity when it occurs. The pulse is sometimes lowered in a sudden and alarming manner from this drug. The author employs in these conditions, large doses of strychnia, at first by the mouth, and later, whenever there is evidence of heart-failure coming on, by the hypodermic method. Results of considerable value have been obtained by the use of hypodermic injections of extract of coco, made up aseptically. Reliance must also be placed in these cases upon the use of nitroglycerin hypodermically. Bleeding, alone, saves certain cases. After venesection, the use of the drugs mentioned is more valuable. In reflecting upon some cases in which general pneumonic congestion at first seemed to be the immediate cause of death, the author has concluded that a slowly forming ante-mortem heart-clot had much to do with the fatal termination. Frequently repeated doses of strong black coffee is often beneficial. Black coffee and alcohol, particularly old brandy or rum, will be assimilated and hold the vitality of the patient when other food or stimulant will be of little or no apparent benefit. Caffein does not replace the use of coffee.

In the treatment followed at St. Luke's Hospital, New York, half-milligramme doses of arseniate of strychnine are usually given together with digitalin and aconitin. The author has for some time watched this method of treatment, and prefers the treatment outlined in his paper to the one with the so-called "trinity pill."

DR. G. L. PEABODY, of New York, said that he was in accord with Dr. Robinson, that at the present time there was no possibility of any other treatment of pneumonia than the symptomatic. One combination of symptoms which is very distressing and which needs treatment, had not been given by Dr. Robinson, namely, pain together with insomnia. Frequently doctors object to the administration of morphine in pneumonia, even in the minute doses in the cough mixtures, on the ground that opium and its alkaloids impair the activity of the respiratory centres; and as here the respiratory system is at fault or impaired, it is undesirable to do anything that would still further impair it. This reasoning is very fallacious, for it is not the respiratory centre that is impaired, but the respiratory periphery; and small doses of morphia do not further impair the respiratory system of the thorax but will often act as a cardiac stimulant and aid matters in the chest. Small doses of morphia, one-sixth of a grain, repeated once or twice if necessary, during the course of the night, will relieve the symptom of pain, or insomnia dependent upon pain or excessive cough, in a way that nothing else will.

It is not necessary to treat every case of pneumonia whose temperature reaches 103° by any form of bath; but if the temperature is particularly high or prostrating, then the bath is exceedingly valuable, in conjunction with friction to the surface.

Dr. Robinson's experience as to the occurrence of

heart-clot as a cause of death in pneumonia was at a variance with that of Dr. Peabody. In many autopsies in deaths from pneumonia, he had very rarely found heart-clot present. He thought that the French authors particularly have been inclined to mistake a post-mortem for an ante-mortem heart-clot. They have relied for a differential diagnosis upon the imprint of the aortic valve upon the clot, which is fallacious. The heart-clot is so infrequent that it is not possible to predict it or to avert it by treatment.

DR. J. C. WILSON, of Philadelphia, said, in croupous pneumonia we have to deal with a pathological condition associated with certain clinical phenomena which vary within the widest limits, so that the croupous pneumonias of infancy, of early life, of adult life and of old age; the croupous pneumonias of alcoholic subjects; the croupous pneumonias which are secondary to antecedent infectious processes; the croupous pneumonias in which there are corresponding or equally varying local lesions; central pneumonias, apex pneumonias, crossed and double pneumonias, and so on, give us a series of clinical pictures which present not only wide variations in symptoms, but indicate an equally varying treatment. So that the treatment of pneumonia to-day, while we have no specific treatment to fall back upon, must be, in the first place, a treatment of expectancy, and, in the second place, a treatment in which the symptomatic factor must enter largely in the process.

The experience with cold baths in the German Hospital in Philadelphia has not been satisfactory in the treatment of any form of pneumonia. The cases have not done well that have been immersed in the cold bath. The application of cold locally to the chest has at times seemed to be of decided benefit.

Regarding venesection, it would appear from the literature of the subject that too much attention is paid to the mechanical indications for venesection. Venesection in croupous pneumonia has often proved advantageous, doubtless by relieving the toxæmia by withdrawing from the blood-supply in large volume the toxic principles to which the nervous symptoms and other serious symptoms must be due. Venesection is therefore useful in cases where the old mechanical indications are not very well marked.

Regarding the use of opium, it is not only safe but often advantageous, in a large proportion of cases of pneumonia, to give small amounts of morphia. Small doses of Dover's powder, two, two and one-half or three grains, at intervals of two, three or four hours, according to the degree of pain or restlessness of the patient, may be given throughout the case.

DR. V. C. VAUGHAN, of Ann Arbor, believed that Dr. Robinson had not used the true digitalin, but a so-called digitalin the greater part of which is digitoxin. The true digitalin, which has been studied by Pfaff, has a wholly different action from that described by Dr. Robinson.

DR. B. ROBINSON said that he had purposed in his paper to oppose what seemingly is the conviction of some eminent practitioners in New York of the efficacy of the so-called "trinity pill," or a modification of it, in the treatment of certain threatening symptoms of pneumonia.

He also wished to direct attention to the fact that we are using drugs very often in a way that is not altogether rational, simply because we do not know what we are using. Different doctors, using what

they suppose to be the same drug, secure different results, which are due to the fact that the agents they use are not the same.

DR. J. W. ROOSEVELT, of New York, stated that the "trinity pill" was not used in all the cases at the Roosevelt Hospital. It had been used in about one-third of the cases during the past year.

DR. S. A. FISK, of Denver, read a paper on

A TREATMENT OF TYPHOID FEVER.

Dr. Fisk exhibited a chart on which his article was based. It was compiled from thirty average cases of typhoid under his treatment, running through three years. The chart is a composite of these cases. The morning temperature for any one day of all the cases are added together and divided by thirty, and a mean temperature is thus obtained. The same way with the evening temperature; so that the chart as presented is a composite of the thirty cases, both with reference to the temperature and the pulse-rate.

The cases were mostly hospital cases, and were obtained, as most hospital cases are, about the fourth or fifth day. They were cases of undoubted typhoid, not selected, having the usual symptoms, including rose spots, and treated almost by routine according to the method outlined.

The chart shows a steady decline in both temperature and pulse-rate from the very beginning and a short duration. Together with this chart was exhibited a typical chart of typhoid fever taken from Pepper.

The treatment is: Calomel, five grains, at the very start, followed by a saline; a tumbler of milk, peptonized if necessary, every three hours, followed in twenty minutes by four minims of the oil of turpentine, four minims of castor oil, ten grains of the subnitrate of bismuth and a drachm of mucilage of acacia. This has the effect of constipating the bowels, so that every second morning anywhere from two teaspoonfuls to a tablespoonful of castor oil is given, the patient usually feeling better on the days on which he takes the oil. Plenty of water, which can be iced if they prefer; lemonade, not to conflict with the milk, if they choose. Delirium of the early stage is quieted with Dover's powder, five grains, repeated once or twice p. r. n. at night. But little attention is paid to high temperature; occasionally the patient is sponged a few times, if the temperature runs very high. Dr. Fisk believes with Dr. Steadman, in the city hospital reports of Boston, that the pulse is a better indicator of prognosis than the temperature. After the temperature has remained normal, or in many cases subnormal, a week or ten days, he begins to feed gradually, preferring animal diet, in the way of broths, eggs and the juice of beef, to starchy foods. If the pulse becomes feeble, he stimulates with whiskey, one-half ounce every two or three hours p. r. n., and uses digitalis or strophanthus, rather preferring the latter.

DR. I. E. ATKINSON, of Baltimore, agreed with Dr. Fisk that milk was the proper diet of typhoid fever patients, but with some qualifications. He had a number of times seen patients whose death was doubtless due to the efforts made in attempting to expel the undigested portion of the casein of the milk which had accumulated in the rectum. He thought that the judicious mingling of liquid animal food with the milk toward the end of treatment of typhoid fever was useful and desirable in nearly all cases.

Insomnia in typhoid, especially that insomnia which

may be called the coma vigil, is extremely ominous. In a number of cases Dr. Atkinson had averted fatal consequences by abandoning the use of ordinary hypnotics and using a slight inhalation of chloroform. In cases where the patient has taken the ordinary hypnotics to the danger point, a few whiffs of chloroform has allowed the patient to go into a slumber and permitted the other hypnotics to assert themselves.

It has been well established that all the symptoms of typhoid are favorably modified by the use of the cold bath. The dry, brown tongue is not present; there is absence of tympanites, subaustus, of delirium and of profound depression, all due to the use of the cold bath, even where the temperature is only temporarily modified.

The efficacy of the line of treatment which Dr. Fisk points out is not shown quite clearly by the chart. One or two cases widely different from the rule would have given quite a different picture. It is not shown that his method is as good as the cold-bath treatment now in vogue.

DR. C. F. FOLSOM, of Boston, thought that Dr. Fisk had had the luck to have treated 80 unusually mild cases. Since Dr. Folsom has been a visiting physician at the Boston City Hospital, probably 1,500 to 2,000 cases of typhoid have been treated; and of these, 300 to 400 were under his care. After he had treated 150 cases, he had been rash enough to write a paper and to generalize from these cases on the treatment of typhoid fever. Now, when he needs a little humiliation he refers to that paper. The number of Dr. Fisk's cases is altogether too small to generalize upon. Medicine, strictly speaking, has very little effect in typhoid, excepting in controlling symptoms which cannot be better controlled in other ways, and those are very few. Almost all the symptoms are best treated with cold water.

DR. J. F. A. ADAMS, of Pittsfield, Mass., expressed his appreciation of the composite charts presented by Dr. Fisk, and thought it would be well for others to follow the same plan. He referred to the fact that typhoid fever in different parts of the country, and at different times in the same locality, is almost an entirely different disease. In Western Massachusetts, about ten years ago, there had been an invasion of intermittent fever, and following this invasion typhoid fever became greatly changed, and instead of following the typical chart of Dr. Pepper, followed more nearly the chart of Dr. Fisk. The mortality was very much diminished; and every form of treatment that was used during the two or three years following the invasion of malaria, was highly successful, because of the mild and short form of typhoid fever.

DR. WM. OSLER, of Baltimore, said that the paper of Dr. Fisk illustrated a common therapeutic fallacy, as it was doubtful whether Dr. Fisk's treatment had any influence on the disease. The chart indicates that he had a peculiarly mild series of cases which would have doubtless recovered with diet and a nurse. For the year ending May 15th, Dr. Osler had treated in his wards at the Johns Hopkins Hospital, 80 cases by the Brand method with a mortality of only just over six per cent., which is a very satisfactory showing for a general hospital to which the cases are brought at all stages.

DR. S. A. FISK said that the criticisms upon his paper were as he expected. While the treatment he outlined was not a specific, yet it had been employed

satisfactorily in Denver for many years, where there has been much typhoid fever. In the fall of 1890, there were 700 cases of typhoid in Denver during the month of October. He believed that there were other methods of treating typhoid fever than by cold baths.

DR. C. F. FOLSOM, of Boston, read a paper on

CASES OF TRAUMATIC HEADACHE.²

Six cases were reported of injury to the head from severe blows, in five of which there were irregular, ragged cicatrices from healing by granulation. In two trephining was done. In the others the cicatricial tissue was excised. The pathological conditions found by Dr. W. F. Whitney were interstitial neuritis, thickened pericranium, increased cell proliferation causing pressure, and, in one case, diffuse hyperostosis of the skull. The symptoms—pain, various morbid nervous and mental indications and petit mal—were relieved. In two cases, there was also an ocular defect as a partial and contributing cause of the trouble.

DR. M. ALLEN STARR, of New York, said that although such a severe operation as trephining was a rather serious matter to recommend for headache, yet there are some cases, such as those related by Dr. Folsom, in which it should be used as a last resort. He related a case similar in many features to the cases of Dr. Folsom. A young man struck upon the head four years ago had suffered very intensely since that time from constant pain at the seat of injury, and his disposition had changed very much. From being a good-natured, fairly intelligent boy, he had become a perfect little devil. He had, at times, attacks of rage in which he would act in a maniacal manner. After all other measures had been tried in vain, Dr. McCosh trephined at the position of the pain, which coincided with the position of the cicatrix. A slight depression was found in the external table, but there was no fracture of the internal table and no adhesion of the dura to the bone. Under the dura was a small angioma, which was taken away. Punctures were made with a hypodermic needle in three directions under the wound, in search of a possible cyst beneath the cortex, but nothing was found. The patient made a good recovery. He has been entirely free from headaches; his disposition has become tractable; and he is in every way a new and better boy.

In a large experience with traumatic epilepsy and other cases of traumatism of the scalp, Dr. Starr has found pain at the seat of the injury the exception and not the rule.

An interesting observation in connection with this case was, that for six weeks subsequent to the operation the boy had an absolute loss of muscular sense in the right hand and arm below the elbow. There was no disturbance whatever, of motor power, no disturbance of touch, temperature or pain senses. It is perhaps the only case on record in which a cortical lesion has produced a loss of muscular sense alone, and settles a disputed question as to the existence of muscular sense as separated from motion and sensation.

DR. FREDERIC P. HENRY, of Philadelphia, read

A CLINICAL REPORT OF TWO CASES OF RAYNAUD'S DISEASE.

The author gave in detail the history of two interesting cases of Raynaud's disease, and exhibited colored sketches of the patients. He then discussed the distinc-

tion between genuine and spurious cases of Raynaud's disease, the genuine affection being distinguished by the stages of local "syncope" and "asphyxia," the absence of traumatism, and symmetrical distribution of lesions. The disease has nothing in common with senile gangrene.

The chief theories of the cause of Raynaud's disease are: (1) that it is due to an endarteritis obliterans; (2) that it is due to peripheral neuritis; (3) that it is the result of vascular spasm. The last is the theory of Raynaud himself, and, in the opinion of the author, is the one that is in accordance with the clinical phenomena. The disease is most prevalent in females and in the young, that is, in those whose vaso-motor system is most impressible. It occurs in paroxysms, which are caused by the surest exciter of vascular spasm—cold. Finally, in several cases, during the paroxysm, there has been dimness of vision, which was shown by the ophthalmoscope to depend upon a contraction of the central artery of the retina and its branches; and in one recently reported by Dr. H. M. Thomas, the attacks of local syncope were followed by a chill, loss of consciousness and convulsions. Such facts are in the highest degree corroborative of Raynaud's view that the disease is due to an "enormous exaggeration of the excito-motor energy of the gray parts of the spinal-cord which control the vaso-motor innervation."

The symptom hæmoglobinuria, occasionally observed, is best explained by the theory of vascular spasm, and is dependent upon an excretion of hæmoglobin which has been separated from the red corpuscles in the peripheral asphyxiated parts.

DR. HENRY M. LYMAN, of Chicago, thought that from the physiognomy of the pictures presented both of the patients were arthritic subjects. The relationship between arthritism and Raynaud's disease should be borne in mind. He had seen quite a number of cases in which that relationship was very evident.

DR. WM. OSLER said: Dr. Henry has referred to a case reported by Dr. H. M. Thomas from my clinic. It was very interesting in this respect, that the attacks occurred only during winter, were always associated with epilepsy, and usually associated with hæmoglobinuria. In connection with the cerebral manifestations of the disease, we have also had under observation a remarkable case in which with the local asphyxia, sometimes without, the patient has aphasia sometimes with and sometimes without hemiplegia.

DR. M. ALLEN STARR said that the disease could be entirely outgrown, and spoke of a case under his observation which had resulted in recovery.

DR. W. H. WELCH, of Baltimore, said that it was not at all clear to him how there could be a connection between hæmoglobinuria and arterial spasm. It is possible that the hæmoglobinuria in these cases belongs to the general type of paroxysmal hæmoglobinuria that follows exposure to cold. The experiments of Ehrlich and of Rosenach indicate that the red blood-corpuscles in this condition are unstable and readily, under the influence of cold, give up their hæmoglobin. It is probable that the corpuscles give up their hæmoglobin in those cases described by Dr. Henry from this cause, and that vascular spasm has nothing to do with it.

DR. F. P. HENRY believed that there was a greater vulnerability on the part of such patients to such causes as dissolve the red blood-corpuscles than on the

² To be published in full in the Journal.

part of other people; but it seemed to him also, that the arterial spasm, the effect of which is to produce local asphyxia, is also concerned in the production of the hæmoglobinæmia. The hæmoglobinuria is a result of the hæmoglobinæmia.

DR. H. C. ERNST, of Boston, then reported

DR. S. C. MARTIN'S RESEARCHES ON THE BACTERIA OF VACCINIA.¹

The paper presented was made up of the work of Dr. Stephen C. Martin upon Vaccine Virus, obtained from a complete set of notes left to Dr. Ernst by Dr. Martin before his death, which occurred last fall, and which he wrote out when he found that he would not be able to continue his work by reason of the illness, that finally proved fatal. Briefly stated, the results of Dr. Martin's investigations are as follows:

- (1) The germ of cow-pox is a bacterium.
- (2) This bacterium, in different stages of development, is in the form of a coccus or of a bacillus.
- (3) It can be isolated and grown in pure culture on blood serum at the temperature of the blood.
- (4) Inoculation on the calf from such cultures readily produces the typical cow-pox, while inoculations in man, have produced typical cow-pox but once in eleven times.

All that remains to be done now is to find under what conditions to grow the pure culture, that it may be uniformly relied upon for vaccination in man.

DR. W. H. WELCH thought that the results reported in this paper were very important, if true. Others have made observations in much the same way, with negative results. The work is left by Dr. Martin in that condition where it needs confirmation.

DR. A. C. ABBOT, of Philadelphia, thought the results obtained by Dr. Martin exceedingly interesting, but felt that subsequent observations might modify the results.

DR. G. M. STERNBERG said he would like to have these experiments repeated by an accomplished bacteriologist. There ought to be no difficulty in confirming the experiments if they were reliable.

DR. H. C. ERNST said that the work had been done in his laboratory, that he had carefully questioned Dr. Martin at different times, but could never detect any fallacy. His object in presenting the work to the Association was to secure confirmation or refutation.

(To be continued.)

ASSOCIATION OF AMERICAN ANATOMISTS.

THE Sixth Annual Meeting of the Association of American Anatomists was held in conjunction with the Congress of American Physicians and Surgeons in Washington, D. C., May 29 to June 1, 1894.

The Secretary reported that Dr. Chas. B. Ewing, Assistant Surgeon, U. S. A., and Dr. F. C. Schaefer, Professor of Anatomy in the Chicago Medical College, had resigned; and that three members had died, namely, Dr. Wm. Lee, Professor of Physiology, Columbian University, Washington; Dr. Wm. B. Towles, Professor of Anatomy and Materia Medica, University of Virginia, and of Anatomy, University of Vermont, and Dr. Corydon C. Ford, Professor of Anatomy and Physiology, University of Michigan.

The officers elected for the ensuing term were: Dr.

¹ To be published in full in the Journal.

Thos. Dwight, of Harvard University, President; Dr. B. G. Wilder, of Cornell University, 1st Vice-President; Dr. F. J. Shepherd, of McGill University, Montreal, 2d Vice-President; Dr. D. S. Lamb, Army Medical Museum, Washington, Secretary and Treasurer. Prof. C. L. Herrick, Denison College, Granville, O., delegate to the Congress of American Physicians and Surgeons; Dr. D. K. Shute, Columbian University of Washington, D. C., alternate. Dr. Theo. M. Gill, Smithsonian Institution, Washington, D. C., was elected to the vacancy in the Executive Committee.

The following new members were elected: Dr. John A. Boger, Assistant Demonstrator of Anatomy, University of Pennsylvania; Dr. H. B. Ferris, Assistant Professor of Anatomy, Yale University; Dr. Robert L. Greene, Professor of Anatomy, University Medical College and Western Dental College, Kansas City, Mo.; Dr. Wm. Keiller, Professor of Anatomy, University of Texas; Dr. Joseph Leidy, Assistant Demonstrator of Anatomy, University of Pennsylvania; Dr. Mary B. Moody, New Haven, Conn.; Mr. Robert O. Moody, Yale Medical School; Dr. Chas. D. Smith, Professor of Physiology, Bowdoin College; Dr. Wm. O. Stillman, Albany, N. Y.; Dr. W. C. Woodward, University of Georgetown, Washington, D. C. Sir Wm. Turner, of London, was elected an honorary member.

The following papers were read: "On the Identity of Structure of Protoplasm with that of Striped Muscle," by Dr. Carl Heitzmann, of New York City; "Some Problems Relating to Cerebral Fissures," Dr. Wilder, of Cornell University; "A Plea for a Methodically Written Text-Book on Anatomy," Dr. Edmond Souchon, Tulane University, New Orleans; "Study of the Human Cranium," also, "Shortening of the Face-Axis in the Evolution of the Mammalia," Dr. Harrison Allen, University of Pennsylvania; "Methods of Estimating the Height from Parts of the Skeleton," Dr. Dwight, Harvard University; "The Perineum and Perineal Body," Dr. Shute, of Columbian University, Washington, D. C.; "The Study of the Muscular Tunic of the Large and Small Intestine of Man in the Region of the Cæcum," also "A Note on the Occurrence of the Scapulo-Clavicular Muscle," Mr. Moody; "Theoretical Anatomy of the Sympathetic System," Dr. Wm. Carr, Columbian University, Washington; "The Female External Genital Organs, a Criticism on Current Anatomical Description," Dr. Lamb, Army Medical Museum, Washington, D. C.

The following papers were read by title in the absence of the authors: "In Our Two Years' Study of Anatomy, What Part of the Subject should be Covered in the First Year's Work, What Part in the Second?" by Dr. A. D. Bevan, Rush Medical College; two papers "The Form and Relations of the Nerve-Cells and Fibres in *Desmognathus Fusca*," and "The Terminology of the Nerve-Cell," by Prof. P. A. Fish, Cornell University.

A STRIKE CAUSED BY TOOTHACHE.—A dentist is attached to all the French lucifer match factories. At one of these all the hands went on strike recently, so it is said, because the dentist made them suffer so much. As their visits are compulsory at certain stated intervals, there was no escape except by the means adopted. The dentist resigned, and was replaced, and the hands returned to their work.

AMERICAN MEDICAL ASSOCIATION.

Forty-Fifth Annual Meeting, San Francisco, CAL., JUNE 5, 6, 7 AND 8, 1894.

FIRST DAY. — TUESDAY.

THE Forty-fifth Annual Meeting of the American Medical Association was held at San Francisco, June 5th. The general session of the opening day was attended by over two hundred members, and was held at Odd Fellows Hall, which was abundantly decorated with orange, scarlet and white festooning. The President, JAMES F. HIBBERD, of Richmond, Ind., called the meeting to order at 10.45 A. M. In the unavoidable absence of both the Governor and the Mayor, Supervisor J. C. James extended to the guests "the freedom of the city and a hearty and cordial welcome."

The formal Address of Welcome by the California State Medical Society was given by DR. J. L. DIMMONS, of Sacramento.

DR. H. R. PLUMMER, Chairman of the Committee of Arrangements, reported that the entire expenses of the meeting had been provided for without calling upon the funds of the Association. After announcing the official programme, he presented President Hibberd with a gavel made of orange-wood (representing the State color) and manzanita-wood. The sides were of gold, one inscribed "A.M.A., S.F., 1894," and the other "James F. Hibberd, President."

The chairman of the various sections were each presented with a gavel of yew and myrtle wood by the physicians of Oregon.

THE PRESIDENT'S ADDRESS.

After thanking the convention for its gift, PRESIDENT HIBBERD delivered the address.

He discussed the various points at which the Association comes into touch with the general medical needs and work of the country. He considered it of the greatest importance that a more satisfactory arrangement should be made of subordinate medical societies in their relation to the American Medical Association. At present many delegates are annually not received because their credentials are not issued by a society technically entitled to representation.

"Every medical man who belongs to any medical society should belong to a county or an equivalent medical society, and every member of a county society should be *ipso facto* a member of his State society, and this is an "open sesame" to the American Medical Association.

By this arrangement, all reputable physicians in the United States would be brought together in the common fold, whose power for good within its legitimate sphere would be limited only by its aggregate wit and energy. Such a consummation would elevate the American profession to a plane for useful work the highest conceivable for the disciples of scientific medicine.

This would in no wise interfere with the organization of medical men devoted to special lines of practice or investigation; indeed, the more of these, and the more special their fields of labor and inquiry, the more rapid will be the development of medical knowledge, the nearer will expert art approach to perfection, and the greater will be the blessing to humankind. In these special and limited societies there will be a concentration of thought and labor that will yield results

advanced and true to a degree beyond hope from a more promiscuous assembly.

All the adherents of the special organizations will be members of county societies, and thereby of their respective State societies, whence, for the asking, they can step through the portals of this Association, and find in our sections a department already organized and at work, into which they can enter, each according to his tastes or qualifications, and feel at home among fellow-laborers.

After discussing in detail the organization and functions of the various sections and committees of the Society, he devoted the remainder of his address to the more public duties and opportunities of the Society. A determined effort should be made by the whole Association to prevent the threatened mistake of reducing the number of assistant surgeons in the army, and to have Congress restore the appropriation for the National Medical Library to its original \$10,000. Reviewing the efforts to secure a National Bureau of Public Health, he said:

"Without rehearsing details, I feel free to declare my conviction that enough has been ascertained of the sentiment of the executive and legislative departments of the government to rob us of all hope of the establishment of a Department of Public Health within the remainder of the nineteenth century."

A bureau of public health, with a commissioner as its chief, within one of the existing departments of the government, was apparently within reach of a united, harmonious, aggressive effort of the profession for a year or two previous to the enlargement of the power of the Marine-Hospital Service by the last preceding Congress, but the excellent work of that service at home and abroad since its increase of authority and means has lessened the anxiety of the government and the apprehension of the public in such degree as to make those in power less attentive to appeals to do what should yet be accomplished.

As to the relation of the medical profession to public opinion on small-pox and vaccination, he said:

"It seems to me the reasonable duty of this Association at this time is to declare and proclaim its unabated faith in the virtue of vaccine to protect from small-pox, to render persons as immune against variola as an attack of variola itself, and that it is innocent of all mischief when the vaccination is done by a vaccinator who is a competent judge of both the purity of the vaccine and the fitness of the vaccinee.

"The progress of medicine in the immediate future must be along biological lines. The microscope has revolutionized our knowledge of the world of living things, and to us has been discovered the generators of the most extensive and persistent and malignant epidemics that periodically decimate the earth, as well as intractable and fatal disorders that we have always with us. Another line of biological workers have carried us back through the morphology organs, tissues and cells to the origin of vital activity in protoplasm, and still more important, in doing so have given us glimpses of the origin and development of the somatic mind that will, when the scheme of nervous organization and function shall be clearly portrayed, dissolve the mystery that has in the past obscured our realization of the true nature of hypnotism, Christian science and other anomalous neuroses which the sciolists and, in an especial manner, those claiming to be doctors, are promulgating and practising to the discredit of true

scientists and the injury of the weak-minded and ignorant classes. We should apotheosize protoplasm, the dividing line between organic and inorganic matter, itself at once the result of the law of perpetual motion with which the Creator endowed the atoms of elemental matter, and the beginning of that phase of energy known as vital activity, which constitutes the entire vegetable and animal kingdom. No one people or class of people can claim exclusively to have opened the way into this more primitive arcanum of nature. The physicists of all nations, botanists, zoölogists, anatomists, physiologists and their congeners, have all participated in this progress. The distinction of Schwann, Virchow, Ferrier, Jackson, Pasteur, Koch and Steinberg is due to their advanced study of biology."

As to the proposed changes in the Code, he said:

"For years there has been a feeling among many most excellent and intelligent working members of the guild that the Code of Ethics did not fairly accord with the demands of the advanced profession in their intercourse with each other, nor with the proper reciprocal relations between the profession and the public, while, on the other hand, many members equally intelligent and devoted to the Association have felt that the Code of Ethics that has guided the Association through nearly half a century prosperously and honorably, and is still a reliable guide in every advanced thought and action, cannot be bettered for our present status, and should not be disturbed."

The Address of the President was referred to a committee of five—Drs. W. T. Bishop, Z. B. Todd, R. B. Cole, F. W. Mann, and J. P. Woodbridge.

On motion of DR. QUIMBY, of New Jersey, a committee was appointed to draft a resolution of protest to Congress against the threatened reduction of the medical and surgical force of the army. Dr. Quimby was appointed chairman of this committee.

The Report of the Treasurer, which was read by the Secretary owing to Dr. Dunglison's illness, showed a balance of \$6,156, in the treasury.

The Secretary's Report was largely devoted to presenting the action of the various State societies as to the revision of the Code. Twenty-one societies were opposed to the change. Nebraska, Vermont and Indiana were in favor of the change. Wisconsin and Florida laid the matter on the table. Three had not yet considered the question, and from eleven no reply had been received.

The following resolution was adopted:

Whereas, Dr. R. J. Dunglison has been for seventeen years a faithful, energetic Treasurer of this Association, without any compensation; therefore, be it

Resolved, That the hearty and unreserved thanks of this Association be cordially extended to him for his efficient and laborious duties on behalf of this Association, and a copy of this resolution be forwarded by the Secretary to Dr. Dunglison.

In the afternoon the sections held their meetings.

In the evening the San Francisco County Medical Society gave a reception to the members of the Association and ladies, which was attended by over five hundred guests.

SECOND DAY. — WEDNESDAY.

The general session of the second day was called to order at noon by the President to listen to the Address on Medicine by DR. C. H. HUGHES, of St. Louis, on

THE NERVOUS SYSTEM IN DISEASE AND THE PRACTICE OF MEDICINE FROM A NEUROLOGICAL STAND-POINT.

He spoke first of the great advance of modern medicine, saying that as Hippocrates drove the devotees of superstition from the Temple of Hygeia, and taught the people that offended gods could neither bring, nor propitiated gods dispel, disease, and as Andreas Vesalius defied the popular prejudice and ecclesiastic power of his day, at the risk of his life, to make his first human dissection, so his professional descendants of to-day continue breaking down barriers of ignorance, of prejudice and superstition in the way of man's happiness and prosperity, unlocking the secrets of Nature's arcanum and setting the captive mind and organism free from the enthrallment of disease.

The recent epidemics of influenza had done much to emphasize to physicians the great therapeutic importance of understanding the intricate influence of the nervous system. All forms and manifestations of disease were dominated by the nervous system, and it was in the slightly disordered functioning of this marvelous organization that the early approach of disease was to be recognized. Even bacteriology was second in importance to an understanding of neurology for the explanation of the origin and onset of disease.

"And now in the sunlight of advancing science, and of the approaching twentieth century, I proclaim that neuriatry and the practice of general medicine are practically one. The practice of medicine is rapidly becoming one of neurological methods, of neuriatry and psychiatry; and the best neurologist, all other attainments being equal, must of necessity make the best general practitioner. The boon of hypnosis and narcosis under the many methods for its induction known to our art, saving the insomniac from the precipice of mental overthrow or neural failure in the lower centres of the cerebro-spinal axis or peripheral nervous system; the power of antiseptics, and through it the wonderful procedures and possibilities of modern surgery, and this *fin de siècle* hygiene; the many and marvellous therapeutic and hygienic advances in promoting the phagocytosis of the toxic bacteria, the destruction of the ptomaines, and in other directions of relief and cure: the discoveries of pathology, histology, medical chemistry, biology, neurology, psychology, psychiatry, and the contributions of surgery, gynecology, ophthalmology, otology, laryngology, proctology, and the other specialties of study and work, have made the later decades of the present century the most memorable in resourceful discovery in the history of medicine or in the history of mankind."

The Librarian's Report recommended the transfer of the library of the Association to the Newberry Library in Chicago.

The Report of the Trustees of the *Journal* was accepted, after some opposition, by a vote of 86 to 33.

THIRD DAY. — THURSDAY.

The Society was called to order at 10.30 A. M. After some general business, and the election of Dr. H. H. Brown of Chicago to fill the vacancy in the judicial council caused by the death of Dr. Murphy, the Committee on the Revision of the Constitution made its reports. The majority report was presented by DR. W. M. HOLTON and the minority report by DR. H. D. DIDAMA. After a sharp discussion, the minority re-

port (opposed to a change) was adopted as the report of the Committee by a vote of 161 to 70.

FOURTH DAY. — FRIDAY.

The closing session of the Association was called to order at 10.30 A. M., the President in the chair.

The first business to come before the meeting was the debate on the

REVISION OF THE CODE OF ETHICS,

which followed closely the lines of the discussion on the Constitution of the day before. The minority report, presented by Dr. Didama, was adopted. The next business was

THE ELECTION OF OFFICERS.

The ticket presented by the Nominating Committee was elected by acclamation.

President, Donald McLean of Michigan. Vice-Presidents — Starling Loving of Ohio, William Watson of Iowa, W. B. Rodgers of Tennessee, F. S. Bascom of Utah. Treasurer, H. P. Newman of Illinois. Permanent Secretary, William B. Atkinson of Pennsylvania. Assistant Secretary, G. H. Rohe of Maryland. Librarian, passed. Chairman of Committee of Arrangements, Julian J. Chisholm of Maryland. Board of Trustees — Joseph Eastman of Indiana, J. T. Priestley of Iowa, John E. Woodbridge of Ohio (unexpired term), J. W. Graham of Colorado, (*vice* D. C. Patterson, deceased). Judicial Council — D. W. Crouse of Iowa, R. C. Moore of Nebraska, T. D. Crothers of Connecticut, G. B. Gillespie of Tennessee, W. T. Bishop of Pennsylvania, C. H. Hughes of Maryland, I. J. Heiberger of the District of Columbia, H. Brown of Kentucky.

The meeting of 1895 will be held in Baltimore.

The Address in Medicine will be given by Dr. W. E. Quine of Illinois; in Surgery, by Dr. C. A. Wheaton of Minnesota; and that in State Medicine, by Dr. H. D. Holton of Vermont.

The question of excluding advertisements of preparatory remedies from the *Journal* of the Association was referred, after some discussion, to the Judicial Council, which decided, after debating the whole afternoon, that one of the advertisements complained of had been inserted through inadvertence. The attention of the Trustees was called to the other one.

The Annual Addresses in Surgery and in State Medicine were then read by title only, as neither Dr. Rohe or Dr. Laplace attended the meeting or sent any manuscript.

MASSACHUSETTS MEDICAL SOCIETY.

THE ONE HUNDRED AND THIRTEENTH MEETING.

The sessions of the Sections in Medicine and in Surgery were held at the Harvard Medical School on Tuesday, June 12th.

The Shattuck Lecture was given on Tuesday evening, by Dr. THOMAS DWIGHT, upon

THE RANGE AND THE SIGNIFICANCE OF VARIATIONS IN THE HUMAN SKELETON.

The exhibit this year was chiefly educational in character. Boards of health were represented by those of Cambridge and Lowell. The latter had an excellent set of diagrams, tables, photographs, etc., illustrative of its special duties. The plant for crema-

tion of garbage, in which Lowell has led the way, was illustrated in detail. Especially instructive tables were those giving the statistics relative to the recent small-pox cases, also to the falling off in the death-rate since the establishment of the board. Mr. James H. Emerton had a unique exhibit of his *papier maché* models of human bones, etc., so valuable for class purposes. Among them were a gigantic skull, two and a half by three and a half feet in diameter, long bones, vertebrae, brain, liver, an encysted trichina, all correspondingly enlarged.

There were the usual exhibits of representative instrument-makers and publishers.

The exhibit of especial interest was that of the Massachusetts College of Pharmacy. It consisted of a carefully prepared and authentic collection of all the crude drugs, preparations, organic products, chemicals, test and volumetric solutions and reagents official in the revised United States Pharmacopœia of 1890, collected, prepared and tested by students of the college. It was a surprise to all to see that the Pharmacopœia was so great a work as to permit so extensive an exhibit of over eleven hundred articles. Few of us realize that provision is made for seventy-two tinctures and nearly twice as many extracts and fluid extracts; and it was new to a good many who saw it that by following Pharmacopœial directions any pharmacist, just as the students had done, can prepare pills, troches, etc., of exact dosage, ready solubility in the body's fluids, and also of elegant appearance. As this pharmacopœial collection is unique, is of unusual interest, and as complete as it could be made, regardless of expense, the College of Pharmacy intends preserving it in its museum for permanent exhibition.

The One Hundred and Thirteenth Annual Meeting was held on Wednesday, June 13, 1894, the President, DR. JAMES C. WHITE, in the chair.

The Secretary reported that during the year 153 members had been admitted, and that 26 had died.

Papers were read upon the following subjects:

ICHTHYOL IN GYNECOLOGY,

by DR. MALCOLM STORER, of Boston.

CHRONIC INFLAMMATION OF THE SEMINAL VESICLES,

by DR. G. W. ALLEN, of Boston.

THE FREQUENCY OF PUERPERAL SEPSIS IN MASSACHUSETTS, ITS DIAGNOSIS AND EFFICIENT TREATMENT,

by DR. EDWARD REYNOLDS, of Boston.

Discussion by DRs. C. M. GREEN, of Boston; E. H. STEVENS, of North Cambridge.

THE ANNUAL ORATION¹

was delivered at noon, by DR. R. H. FITZ, of Boston.

THE ANNUAL DINNER

was served at one o'clock, there being about nine hundred and fifty members present.

At the close of the dinner the Anniversary Chairman, DR. SILAS D. PRESBREY, of Taunton, spoke as follows:

Another year has passed, and once more our Society welcomes you to her annual festivities. At our last meeting we were reminded that we were then at the beginning of a great national celebration; at this time

¹ See page 581 of the Journal.

the Columbian Exposition is finished, and we may well consider some of the contributions that were made by the medical profession of the State, and we may justly take pride in the work that was done by members of this Society.

The Massachusetts State Board of Health has received high praise, both in this country and abroad, for the comprehensive exhibit of its work and its methods. The *Journal of the American Medical Association* says: "This exhibit is an object-lesson well worthy of study by other States, as owing to the increased density of population and increase of manufacturing wastes, our water-supplies are annually becoming more polluted, and the necessity for such work more and more imperative." Thus the oldest board of health of the country justified the opinion that it is a leader and an authority in the work in which it is engaged.

The Medical Department of Harvard University made a striking exhibit of the most advanced methods of instruction, and in some respects methods entirely unique. A Harvard man could not fail to feel a thrill of satisfaction when he found himself surrounded by the familiar frozen sections and the mammoth models. Studies in physical culture, as expressed by charts, photographs and models, showed the zealous care with which the health and growth of the Harvard student are watched and promoted.

I would not miss the opportunity to call to your attention an innovation of the last year which seems to me especially worthy of your notice and of your patronage. Through the school year the Faculty of the Harvard Medical School has given a course of evening lectures on special subjects, which physicians were invited to attend without charge. The lectures were given on each Wednesday evening from October to May, vacations excepted. This work was done by gentlemen of great experience in teaching, and each lecturer is an acknowledged authority on the subject which he handled. I hope this, the first and experimental year, may prove the beginning of a permanent custom.

The third feature of the medical year is the adoption by the Legislature of an Act to provide for the Registration of Physicians and Surgeons in the State of Massachusetts. I am happy to say that after hard work and careful management the Act has passed both branches of the Legislature and has received the Governor's signature.

Fellows, the weightier matters of the physician's work and duty have had ample discussion for two days in the neighboring halls; here we have met for refreshment and entertainment. How well your admirable Committee of Arrangements have attended to the refreshment you are all able now to judge; it only remains for me to introduce to you the entertainment.

Dr. Presbrey then offered the first regular sentiment: "The Massachusetts Medical Society," which was responded to by the incoming President, Dr. F. K. PADDOCK, of Pittsfield, who spoke as follows:

It would seem to me more proper that the response to this toast should be made by my predecessor, Dr. J. C. White, who has so faithfully and successfully conducted the affairs of the Society for the last two years. It will be my greatest ambition to perform the duties of this office as satisfactorily as he has accomplished them.

There is no question about the importance and emi-

nence of the Massachusetts Medical Society. Its members embrace the best medical talent in the State, and for seventy years it exerted a controlling influence over the practice of medicine throughout the Commonwealth. In 1859, for various reasons, the Legislature deprived the Society of this control, so that for thirty-five years the people of the State have been preyed upon and defrauded without opposition by hordes of quacks and charlatans.

The dignity of this Society and the welfare of the community demand that this condition shall be changed. Other States have laws to regulate the practice of medicine; this State should do likewise. During the last session of the Legislature a successful effort has been made to establish a law to regulate the practice of medicine. For this legislation we are indebted to a member of this Society, Dr. Harvey, of Westboro'.

The good influence of this Society is increased by every regularly educated, respectable physician who joins it; and I think that it is the duty of the members to personally solicit candidates for admission.

"Lessons from the Experience of Two Years in the Presidency of the Massachusetts Medical Society."

DR. J. C. WHITE, in response, said: I told you at a former dinner, in the few words I then addressed to you, that I hoped to have more of interest to say when I should have become better acquainted with the condition of the Society and the functions of the high office with which you have honored me. There is no other opportunity offered to the President to meet so large a gathering of members of our Association, and to present any opinions he may have formed concerning its welfare, as this occasion, so that he must avail himself of it for this purpose.

During my term of office I have visited, for purposes of observation and inquiry, all the eighteen districts into which our Society is divided, and which present so striking a diversity in their physical aspect and in the character of their inhabitants, as in the long stretch of sandy Barnstable, with its remote settlements, the lonely and sparse hill-towns of Berkshire, and the many busy centres of factory life, with their dense throngs of foreign peoples. We hardly appreciate here in the metropolis and its immediate surroundings how unlike our own are the life and professional relations of these other districts, which are so essential a part of our State Society. Think of a Massachusetts township with only 219 inhabitants, and of these all but 19, Indians; and of 80 or more towns in the State without a resident Fellow of this Society. It has been my object to study its workings in all these regions, and to gather the views of its members living under such diverse conditions as to how satisfactorily it may be fulfilling its mission.

Let me first briefly define what, in my opinion, should be the chief objects of this Association:

- (1) The cultivation of friendly relations and mutual support among its members.
- (2) The establishment and maintenance of rules to regulate the practice of medicine in its relations to the community.
- (3) The stimulation of progress in our art by meetings for medical improvement, by encouragement of scientific research, by the foundation of scholarships and lectureships.
- (4) The elevation of medical education.
- (5) The securing and enforcement of laws for the

preservation of the public health and the enlightenment of the people concerning it.

Now I have found that, on the whole, a satisfactory loyalty to these objects prevails throughout the Society; that much interest is everywhere manifested in the district meetings, and that the papers there presented are most praiseworthy. In some parts of the State, where the towns are thinly peopled and widely separated, the attendance was not large.

It was a great surprise to me to note how small a proportion of the physicians in many places were graduates of our Massachusetts schools of medicine. Thus, in one district containing 36 Fellows, only three, and in another of 38 members, but two, had received such a degree of M.D. In the seventeen districts of the State (omitting Suffolk), representing 1,200 members, only 463 are graduates of our medical schools.

Again, I was astonished to learn how many physicians were practising medicine in this State, graduates of medical colleges whose diplomas are recognized by us, of excellent reputation, regarded as their peers by our Fellows, their associates in private medical bodies in many instances, and with whom they consult freely, and yet who are not members of the Massachusetts Medical Society. Many of these are gentlemen who have come from other States, where they were in good standing in their State societies. I cannot give you their exact number, but it is very large. The president of one district informed me that there were twenty such men in his city. Another president of a small district named twelve to me. The Treasurer of the Harvard Medical School Alumni Association informs me that 775 of its members reside in this State, and that of this number 118 are not members of our Society, or 15 per cent. Now it is very important that every good physician should be enrolled upon our list of Fellows. It is better for them, much better so for us, and why are they not members? Because in the majority of cases they are unwilling to run the possible risk of being stamped by our examining boards as incompetent. There can be no doubt that the examinations of our censors have often been too severe, and of a character to test the school rather than the practical knowledge of the candidate. Within two years two distinguished professors, recently become residents amongst us, and desiring membership, have refused to offer themselves to the test of such methods of examination. How many of my colleagues on this platform would venture to act otherwise? At the time when our present laws defining the duties of censors were formed, the requirements for a medical degree in most or all schools were lax and insufficient, and the Society had to protect itself by an independent and rigid examination. It is very different now, and in all good schools the requirements for the degree of M.D. give practical assurance of sufficient medical knowledge for our purpose. Yet within the last two years graduates of the Harvard Medical School have been turned aside by our censors. At a meeting of one district society I heard read aloud the names of several young men who had failed to pass the examination of a neighboring board. Can one wonder that our present system repels candidates, and serves to keep good men out of the Society, whereas its object is to get them in? You are aware that at a recent meeting of the Council a system has been adopted by which the entrance to this Society may be made more lax, but still sufficiently protected. This plan is to

come before a special meeting of the Society next October, and deserves your careful consideration.

"The Commonwealth of Massachusetts."

LIEUTENANT-GOVERNOR WOLCOTT said that, having addressed the Society before, it required the delicate touch of a Hawthorne to give any charm to twice told tales. The two characteristic actions of the medical profession which were unparalleled in any other are, first, the gratuitous treatment of the poor in hospitals and asylums, whereby the most unfortunate person can call upon and receive the aid of the most skilful physician; and, secondly, the close observance of that unwritten law, which has more force than statutory law, that whatever device or remedy for the alleviation of suffering a physician may by skill or study discover, shall be freely given to the public. The benefit to a community of the scientific knowledge and enthusiasm which the medical profession brings so freely to the service of the public good is not easy to estimate. For this, too, Massachusetts offers her congratulations and acknowledgment.

The Medical Registration Bill is certain to prove of permanent utility to the Commonwealth, although Massachusetts comes a little haltingly into line. If it but keeps the word "doctor" back to its old meaning of teacher—a teacher of sound sanitary law, of a high standard of honor, a teacher of the laws of public health—so that no charlatan can use it, the Governor and members of the Legislature are entitled to your thanks and those of the community.

"The City of Boston: New England's Thought-Centre."

MAYOR MATTHEWS being unable to attend the dinner, no response was made to this toast.

"Harvard University."

PRESIDENT ELIOT said that in looking back over the last twenty-five years nothing was more clearly marked than the progress of professional education, and in this medicine has taken the lead. There has been more gain in the education of physicians and surgeons than in any other department of the university. He had often felt the wish that medical schools in general, and those of Massachusetts in particular, were producing more country doctors. The country doctor should be given chief place. He needs a better education than the city doctor. He has no specialist at his elbow. He must know himself, and act himself. The training of the country doctor is most important, and needs to be developed, for he is more than a physician. He is a missionary. He is a social reformer—a sanitary reformer. He brings to his community the scientific spirit, a most valuable and important thing. The country doctor has one immense privilege and great happiness for his comparative isolation, that of living in the country, an inestimable prize for himself and for his family—as one who from long observation of where the most promising students come from can testify.

Commenting on the examinations of the Society, he said it had been proven useless to examine at one time a man on studies which had taken six or seven years to acquire. This practice had been given up in the university, and it was not reasonable to do so in this Society. What is wanted is an examination which will test power. The question which the Council

should put to each candidate is not, "What do you know of this book or that book?" but "What can you do in judgment and tact and good temper for your patients?"

"The Physician as seen by the Lawyer."

ATTORNEY-GENERAL KNOWLTON spoke of the general relations of the lawyer and the physician. As the physician had been his first friend in this world, so he would be with him at the close of life to make it easy. It seemed to him that the same quality of character was essential to success in both the lawyer and the physician—that peculiar quality which for lack of a better term is called "nerve," the ability to face great danger and risk in an impassioned manner uninfluenced by personal feeling. The doctor who attempts to care for his own case was likened to the man who makes his own will; both are more daring than wise.

"The Physician as seen by the Journalist."

HON. WILLIAM REED, JR., spoke of the earlier attempts to secure a Medical Registration Bill, in some of which he was actively engaged himself while in the Legislature. He congratulated the Society, not that the members had protected themselves, for they needed no protection beyond the honor of the Society, but that the people of the State had been protected.

"The Medical Man of Japan."

REV. ARTHUR M. KNAPP spoke of the remarkable progress of medical science in Japan since 1854, and the magnificent work done by the medical school of Tokyo, which was the first step in the formation of the great university there. He related many interesting facts about the medical history of Japan.

MASSACHUSETTS MEDICAL SOCIETY.

COUNCILLORS' MEETING.

THE annual meeting was held at the Medical Library, Boston, on Wednesday, June 13, 1894.

The meeting was called to order at eleven A. M. by the President, DR. JAMES C. WHITE. One hundred and fifty-five Councillors indicated their presence by signing the roll.

The Secretary read the names of 153 Fellows admitted since the last annual meeting, and of 36 whose deaths had been recorded.

The Treasurer, DR. FORSTER, presented his report, which was accepted, showing the receipts of the Society for the year ending April 15, 1894, with the balance on hand at the beginning of the year, to have been \$11,887.92, and the expenditures \$8,895.09, leaving a balance of \$2,992.83.

DR. DRAPER, for the Committee on Membership and Finances, reported the names of four Fellows whom the Committee recommended to become retired members; of eight to be allowed to resign; and of four to be dropped for non-payment of assessments.

The report of the Committee was adopted.

It was also voted, on recommendation of this Committee, that \$1,900 of the surplus in the treasury be distributed among the district societies.

The Committee on Publications reported that DR. ROBERT T. EDES, of Jamaica Plain, has been ap-

pointed to deliver the Shattuck Lecture at the annual meeting of the Society in 1895.

The Librarian, DR. BRIGHAM, presented his report. The Committee on Nominations reported, and the following were chosen officers of the Society for the ensuing year: President, Dr. Franklin K. Paddock, of Pittsfield; Vice-President, Dr. Frederic A. Sawyer, of Wareham; Treasurer, Dr. Edward J. Forster, of Boston; Corresponding Secretary, Dr. Charles W. Swan, of Boston; Recording Secretary, Dr. Francis W. Goss, of Roxbury; Librarian, Dr. Edwin H. Brigham, of Boston. Dr. Alfred Worcester, of Waltham, was chosen Orator, and Dr. Herbert L. Burrell, of Boston, Anniversary Chairman, for the annual meeting of the Society in 1895.

Voted, That the next annual meeting of the Society be held in Boston on the second Wednesday in June, 1895.

The following Standing Committees were appointed: Of Arrangements: Drs. H. Jackson, J. C. Munro, A. Thorndike, A. K. Stone, J. G. Mumford, N. V. Pierce.

On Publications: Drs. B. E. Cotting, O. F. Wadsworth, G. B. Shattuck.

On Membership and Finances: Drs. F. W. Draper, J. Stedman, E. G. Cutler, L. R. Stone, A. H. Johnson.

To Procure Scientific Papers: Drs. H. P. Bowditch, F. H. Zabriskie, H. L. Burrell, S. B. Woodward, L. Wheeler, C. W. Townsend.

On Ethics and Discipline: Drs. G. E. Francis, F. C. Shattuck, C. G. Carlton, E. Cowles, J. F. A. Adams.

On Medical Diplomas: Drs. E. J. Forster, H. E. Marion, E. N. Whittier.

DR. C. M. GREEN called attention to the fact that for two years there has been no session of the Section in Obstetrics and Gynecology at the annual meeting of the Society; that owing to the interest of members in the other sections it is difficult to obtain a satisfactory audience, and an injustice to ask for the preparation of papers. He moved, and it was voted, that the rule by which the Obstetrical Section was established be rescinded, and that the Section be abolished.

DR. G. B. SHATTUCK offered resolutions which were adopted:

That a Standing Committee on State and National Legislation be appointed at the annual meeting of the Councillors.

That this committee shall consist of five members, including the President, *ex officio*.

It shall be the duty of this committee to take such action in reference to proposed legislation as shall, in their opinion, be most conducive to the interests of the medical profession, and to make an annual report thereon.

DR. GAGE offered the following, which, after some discussion, was adopted:

Whereas, the expenses attending the annual meeting of the Society have been increasing in recent years, and now exceed what seems to be a reasonable amount for this object; and *whereas*, it is desirable that such expenditures should be more under the immediate control of the Council than hitherto,

Voted, that the Committee of Arrangements for the anniversary shall hereafter consist, in part, of members of the Council.

DR. J. F. A. ADAMS presented the following, which was passed:

Whereas, it is evident that the affairs of the Society can be best administered by the coöperation of those who have the widest experience with its condition in all sections of the State,

Resolved, that in the opinion of the Council it is advisable that District Societies shall include in their election to this body such ex-Presidents of the State Society as may reside therein.

The following preamble, together with amendments to the By-Laws abolishing the office of Anniversary Chairman were, on motion of Dr. CHEEVER, adopted :

Whereas, it is more consistent with the dignity of the office, and in conformity with the custom of all societies of such high character, that the President should preside over all meetings, and especially at the most important public occasion, the annual dinner : *Resolved*, etc.

Adjourned at 1.15 P. M.

AMERICAN CLIMATOLOGICAL ASSOCIATION.

ELEVENTH ANNUAL MEETING, WASHINGTON, D. C.,
MAY 29, 30, 31 AND JUNE 1, 1894.

FIRST DAY. — TUESDAY.

AFTER a brief Introductory Address, the President, DR. ANDREW H. SMITH, New York, read a paper on

ALIMENTATION IN PULMONARY DISEASE.

In pulmonary affections the problem of alimentation is complicated by special conditions growing out of the functions of the affected organs. We are too apt to regard nutrition as if it were only another term for digestion, and practically to assume that, if the food taken into the stomach goes through the proper changes in the alimentary canal, and the nutritive portion is properly taken into the blood, that is all with which we need have concern. The products of digestion when received into the circulation are not blood. They represent neither serum nor corpuscles: they are, in fact, dead matter, requiring to be vitalized by the process of assimilation before they become a part of the living blood.

Of the manner in which this change takes place we know almost nothing. But we do know that an essential factor is the process of oxygenation that takes place in the lungs. Material which has not undergone this change is, for the time being, not only useless to the economy, but a hindrance to proper metabolism.

If, then, a considerable obstruction exists to the entrance of air into the lungs, it follows that an addition of more nutritive material to the blood than can be acted upon under the circumstances of crippled respiration, will only add to the circulatory embarrassment and aggravate the condition of the patient.

Under these conditions, therefore, we should study in acute cases to give as little nourishment as will sustain the vital powers, rather than as much as the stomach can be made to digest.

If we pass to chronic affections of the lungs, the same principle will hold good, with certain important modifications in practice. We have a chronic condition in which we are confronted with a restricted hæmatosis on the one hand and urgent necessity for a high degree of nutrition on the other. The difficulty of reconciling these two conditions will be in proportion to the degree of lung-insufficiency.

In the minor degrees of chronic lung-insufficiency,

the respiratory movements make up in frequency what they lack in amplitude. So long as this compensation can be fully maintained, there may be no considerable defect in hæmatosis, and, in the absence of fever, no marked failure of nutrition. But, sooner or later, a time comes when the respiration is so far impaired that enough oxygen cannot be taken into the blood to act upon such an amount of nutritive material as is necessary for the full maintenance of the economy. The moment this stage is reached, the appetite fails in proportion to the defect in hæmatosis. Unless we can improve the hæmatosis, and with it the whole process of metabolism, we shall only do harm by high feeding. Digestion in these cases fails as well as assimilation. Moreover, in these chronic cases with pronounced anæmia and emaciation, we cannot rely chiefly upon nitrogenous food, as we must do in acute affections of the lungs. The heat-producing hydrates and fats are required in addition, and these are more difficult of assimilation. A vicious circle is established, the defective hæmatosis aggravating the dyspepsia, and this in turn resulting in greater poverty of the blood. Under these conditions, life in the open air is of the utmost importance.

The speaker has obtained much benefit in cases of this kind from rectal injections of defibrinated blood. This material seems to be absorbed almost unchanged, the corpuscles as well as the serum; it being a frequent experience that no trace of blood is found in the next defecation. There being no digestive action upon the blood, its absorption into the venous circulation is almost equivalent to transfusion very slowly performed; and but little change in the way of hæmatosis is required to fit the added material for the immediate use of the tissues.

Dr. Smith described a case of phthisis treated in this way. There was an enormous cavity at the summit of the right lung; the patient was emaciated to the last degree, weighing only 101 pounds. After two weeks of the treatment with blood enemata, he gained seven pounds. At the end of three months he left the hospital; the cavity in the lung had contracted greatly; expectoration had nearly ceased; he had gained 33 pounds.

Dr. Smith said: Though defibrinated blood is preferable for this purpose, good results may be obtained with the materials usually employed for rectal feeding, provided the patient can live much in the open air.

In the discussion which ensued, DR. KARL VON RUCK referred to twenty or thirty cases in which he followed the method suggested by Dr. Smith, and carefully observed the number of corpuscles and the hæmoglobin present. All the cases showed marked improvement in the blood condition.

The paper of DR. BOARDMAN REED, of Atlantic City, on

THE RELATION WHICH ALIMENTATION SHOULD BEAR TO OXYGENATION IN LUNG DISEASES,

was read by DR. JAMES B. WALKER.

Dr. Reed concurred in the opinion of Dr. Smith, that any excess of food beyond the amount which can be perfectly digested and assimilated, is injurious. When the intake of oxygen is large, as in the case of a robust person exercising actively in the open air, a maximum amount of food can be safely given. When, on the other hand, a patient has one or even both lungs crippled, the amount of food which he can digest

and thoroughly oxidize into a nutritive pabulum for the uses of the economy, is much less. Between these two extremes are found patients with all possible degrees of capacity and opportunity for absorbing oxygen, and in consequence equally varying degrees for digesting and assimilating food. Evidently, then, there is such a ratio as has been assumed. It is exceedingly important that this fact be borne in mind in deciding the proper feeding of a case of lung disease.

Dr. Reed gave a detailed report of six cases (four of the number being now either well or convalescent), concerning which he says: The results are, on the average, considerably better than when it was my practice to encourage the fullest feeding of consumptive patients. They have been obtained with the aid of so little internal medicine, and that addressed almost exclusively to the digestive tract, that the management of the diet and hygienic regimen generally should receive the credit.

An abundance of pure healthy blood circulating normally in the lungs is the most essential prerequisite to a cure of phthisis pulmonalis. Hence the paramount importance of looking closely to the blood-making processes by securing as perfect digestion as possible, together with a complete oxidation of its products, so as to spare the lungs from the injurious task of assisting in the excretion of the poisonous compound resulting from suboxidation and decomposition. To obtain these ends satisfactorily, the total amount of aliment ingested must not be in excess relatively to the amount of oxygen absorbed. Dr. Reed considered the importance of selecting a special climate for such cases greatly over-estimated, though changes of climate exert a powerful stimulant action upon nutrition, for a few months especially.

THE METHODS AND VALUE OF SUPERVISED EXERCISE IN THE PROPHYLAXIS OF PULMONARY PHTHISIS,

was the title of a paper by DR. GLENTWORTH R. BUTLER, Brooklyn. The substance of Dr. Butler's paper was as follows:

Pulmonary tuberculosis is essentially a disease of defective nutrition. Although of microbial origin, a certain vulnerability of the tissues precedes and underlies the bacillary growth. The same individual may be at one time vulnerable, at another time invulnerable, as shown by the onset and arrest of the disease. The therapeutics of this disease demands that every possible means should be employed to strengthen the resisting power of the tissues. Aside from measures designed to prevent tuberculous infection, these means may be thus enumerated: climate; abode and out-door life; medication, general and local; personal hygiene and habits of life; diet; exercise, general and local, with its corollary, rest.

For the pretuberculous status and incipient cases, one of the valuable resources for permanently increasing vital capacity is "pulmonary gymnastics." The appreciably best method of taking such exercise is under the instruction and supervision of a trained operator, acting under general directions from the physician. This method admits of beginning with the gentlest exercise and progressing to the severest, in accordance to the patient's varying condition. It ensures the patient's attendance and economizes the physician's time. Graduates of physical-culture schools can be found in all of the larger and most of the smaller towns and cities.

The paper embraced a detailed discussion of the physiologic effects and relative advantages of the use of compressed air, breathing-tubes, and voluntary exercise, with a report of cases, and a series of photographs from the living model.

Dr. E. O. OTIS, in the discussion, laid great stress on the careful supervision of exercises by the physician, in contrast with the ordinary hap-hazard direction, "to take physical exercise." He said: "If this careful arrangement of exercises, in the first place, and careful supervision, in the second place, can be followed out with pretuberculous cases and incipient ones, as Dr. Butler has suggested, much might be achieved. The practitioner who treats cases of phthisis is bound to study the application of chest gymnastics as he would the effect of any drug he uses.

SECOND DAY. — WEDNESDAY.

The second day's proceedings began with a paper entitled:

THREE YEARS' EXPERIENCE IN THE SANITARIUM TREATMENT OF PULMONARY DISEASE, NEAR BOSTON, by DR. VINCENT Y. BOWDITCH, which will be published in full in the JOURNAL.

Dr. R. G. CURTIN, in a paper on

CREASOTE, GUAIACOL AND BENZOYL OF GUAIACOL IN PHTHISIS,

gave a brief *résumé* of observations in the use of these drugs, covering a period of fifteen years. Concerning guaiacol, he says: "In acute catarrhal phthisis with high temperature, little or no good is to be expected from its use. In acute tuberculosis no material benefit results from its employment. The class of cases that seem to be most benefited is the one in which we have slight elevation of temperature with poor nutrition, slow digestion with fermentation. Guaiacol has no specific effect upon the bacillus. In cases where the process was slow, beneficial results followed the use of guaiacol."

Dr. Curtin's conclusions were as follows:

Guaiacol is not so irritating to the stomach as creasote. Guaiacol is not so liable to produce irritation of the kidneys, nor to be followed by hæmaturia.

Among the advantages of guaiacol are: First, it is more easily taken; second, the process of manufacture insures purity; third, the exact quantity of medicinal substance administered is known.

Dr. A. L. LOOMIS: We find no evidence that these drugs have any other effect than to aid assimilation and digestion in a certain class of individuals. We cannot use them hypodermically. Whether we shall gain something by the use of the vapor seems to me still unsettled. They have no specific action upon the bacillus.

Dr. JUDSON DALAND reported five cases at the Philadelphia Hospital, in which the object was to see if guaiacol, administered by the skin, had any effect upon the temperature. No results were obtained.

Dr. VON RUCK reported one case where a dangerous fall of temperature followed the administration of guaiacol by the skin; the other cases showed little change.

SHALL ANYTHING BE DONE BY LEGAL AUTHORITY TO PREVENT THE SPREAD OF TUBERCULOSIS?

Dr. FREDERICK I. KNIGHT, of Boston, called at-

tention, in this paper, to the fact that, though twelve years had elapsed since the infectious nature of tuberculosis was established beyond question, very little had been done to prevent its spread. This was attributed by Dr. Knight not to a want of belief in the infectiousness of the disease, but to the magnitude of the problem and manifest difficulties in dealing with it. Dr. Knight claimed, however, that boards of health are organized to keep people informed, and not in ignorance, of the dangers by which they are surrounded; and gave notice that in the business meeting he would introduce a resolution upon this subject.¹

An interesting discussion followed the presentation of this resolution. All the members agreed that something ought to be done to prevent the spread of tuberculosis; the only difference of opinion being as to the means. Much regret was expressed as to the present constitution of boards of health in this country and their connection with politics; Massachusetts was congratulated upon the high character of the Chairman of its State Board of Health.

(To be continued.)

Recent Literature.

A Practical Treatise on Diseases of the Skin. Third edition, thoroughly revised and enlarged. By JAMES NEVINS HYDE, A.M., M.D. Philadelphia: Lea Bros. & Co. 1893.

Ten years have passed since the appearance of the first edition of this excellent text-book of skin diseases. The third edition, just issued, fulfils all the expectations warranted by the great accumulation of dermatological material since the earlier editions were brought out, and puts this work at the head of the modern American treatises on skin diseases. The author has introduced thirty-five new diseases in this edition, and has corrected and improved almost every page. He is especially to be congratulated on his chapter on tuberculosis, which he has amended so that lupus vulgaris, and scrofuloderma assume their proper place as varieties of this disease, and are intelligently considered in the light of modern pathology. Five plates and twenty-two wood-cuts, all of great excellence, have been added to the illustrations. The excellence of the chapters on treatment, together with the care that has been bestowed on subjects that have acquired new interest, make the book one to be warmly recommended to any one seeking for a reference book in this branch of medicine.

A Treatise on Headache and Neuralgia, including Spinal Irritation, and a Disquisition on Normal and Morbid Sleep. By J. LEONARD CORNING, M.A., M.D. With an Appendix, *Eye Strain, a Cause of Headache*, by DAVID WEBSTER, M.D. Third edition, 8vo, pp. 275, 17 illustrations. New York: E. B. Treat. 1894.

To the third edition of this book a chapter has been added on the localization of the action of remedies upon the brain. This method of treatment consists of applying the remedies to the nasal mucous membrane, and increasing their effect by compression of both jugulars.

¹ The article of Dr. Knight, including the resolution, will be published in full in the Journal.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, JUNE 21, 1894.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE PLAGUE IN CHINA.

THE word plague has had but little of its terrible real meaning for Europeans for many years. Eastern Russia and Persia had a short and mild experience some fifteen years ago; but practically Europe has been free from the disease since 1665, when London was scourged. Its native home is China; and in some cities there it appears every year during the dry season, but with a mild degree of poison, attacking only the poorer class of natives. The present epidemic is so widespread as to be of serious menace, as it has already attacked European settlers in the healthy portion of the cities.

Toward the end of April the extent of the outbreak at Canton became so alarming that the Board of Health at Hong Kong wrote to the Consular Surgeon at Canton, for a report of the true state of affairs. Dr. Renzie replied as follows:¹

"The first outbreak occurred in the last week of March, and was confined to a poor quarter of the city, near the South Gate. This neighborhood we visited on the 8th of April, and had an opportunity of examining one or two cases and also inquiring into the sanitary condition of the houses.

"The symptoms are as follows: With or without premonitory warning in the shape of malaise or chill, there is a sudden onset of fever rising to 105°, or over. There is much headache and cerebral disturbance, accompanied by stupor. In from twelve to twenty-four hours a glandular swelling occurs in the neck, arm-pit, or groin, rapidly enlarging to the size of a fowl's egg; it is hard and exceedingly tender. With or without a decline of the fever, the patient sinks deeper into a condition of coma and dies usually at the end of forty-eight hours or sooner. If six days are reached recovery is hopeful. The glandular swelling shows no signs of suppuration. In some cases epistaxis or vomiting of blood occurs; petechiæ appear in a few cases, but no regular eruption. Such are, briefly, the symptoms at the beginning of the disease. It was then extremely fatal, over 30 deaths having occurred in the small street we visited. The mortality was high, being over 65 per cent. of the patients attacked, whose houses are occupied by laborers and artisans; they are small and badly ventilated houses, with damp earthen floors. Underneath the flag-stones in front of the houses in question is the usual drainage arrangement, which, at the period of our visit, was in a very insanitary condition on account of the lack of water and in consequence of the prolonged drought.

¹ Report of Sanitary Board: Hong Kong Daily Press, May 11, 1894.

The people stated that at first many dead rats were found about the houses, but that after a few days these animals entirely disappeared.

"On the 17th of April we had again an opportunity of examining some cases in a Chinese hospital situated inside the North Gate of the city. The cases were all of a milder character than those we had seen the previous week. The native doctor in charge informed us that whereas the patients he treated at the outset of the epidemic died at the rate of about 80 per cent., the mortality had declined to about 25 per cent., and he seemed to be of the opinion that the disease was declining. Since then the disease has extended to other parts of the city, and also to Honam. We have had no opportunity of examining cases recently, but from what we can gather it appears to have in no way diminished either in frequency or severity. It is impossible to obtain reliable statistics as to the mortality, and we therefore refrain from expressing our opinion on this point."

The unspeakable filth of the poorer quarters of the Chinese cities had been much increased by the long drouth. For nearly seven months there had been no rain to speak of, but only a few light showers. The long time without serious epidemic had made the supervision of sanitary conditions lax, and the uncleanness of the poorer quarters polluted the air for considerable distances. A general cleaning out was at once ordered at Hong Kong, but the water-supply was too scanty to allow of thorough cleansing.

Some idea of what a cleaning up in a Chinese city means may be had from the Report of the Sanitary Board concerning the first general cleaning out some years ago. This report says, that during the eight days on which special facilities were offered for the work, no less than 2,400 tons of rubbish were removed in excess of the normal quantity, which was stated to be 100 tons a day. Of late years there has been no such accumulation; but the drainage is still notoriously defective, and the amount of surface and concealed filth is sufficiently large.

The cleaning and disinfecting at Hong Kong was begun too late, however, for the plague had already appeared, and some twenty cases were at that time in the Tung Wah Hospital. The early deaths were reported as due to fever; and it was only when several had occurred in quick succession that the true nature of the disease at Hong Kong was realized. At first, it was hoped to keep the disease down; but the upturning of dirt appeared to favor its spread, until even the better portions of the city and the foreign inhabitants were attacked. The mortality in Canton at first was 80 per cent., falling for a while to 30 per cent., but soon rising to 55 or 60 per cent., where it remained until the end of May.

Under ordinary conditions the disease is reported by Dr. Lowsan, of Hong Kong, not to be contagious, "but if healthy persons remain too long in the same atmosphere there is great probability of their catching the disease. The attendants at the Canton Hospital take care to smell of a bag of sandal-wood and aromatics during their work, and say that none of them have taken the disease. The disease appears to me more of a chemical origin than a bacteriological."

The disease had gathered such headway that it is hardly possibly to expect the recent much longed-for rains to do much in the way of checking the scourge.

Its course and developments unavoidably suggest a similarity to anthrax.

The terrible mortality rate, over 80 per cent., and the frightful rapidity of the disease, death ensuing often in twelve hours, should teach the lesson that cleanliness and sanitation should be the constant and precautionary care of a people, and not the last resort of a plague-stricken city.

MEDICAL NOTES.

THE PLAGUE IN CHINA. — A terrible epidemic of the plague is now raging in China for the first time in eleven years. The disease is reported by medical observers to be very similar, if not identical with, the Great Plague of London in 1665. The disease appeared first in Canton the 1st of April, and spread with frightful rapidity among the poorer classes until the deaths had numbered many thousands. Some statements put the mortality at 60,000. About the 8th of June the disease appeared in Hong Kong, where it is now epidemic. At first only the natives were attacked, the mortality being about ninety per cent., but finally the European inhabitants have become victims to the disease, and several deaths have been reported. The daily death-rate in Hong Kong is nearly one hundred. In Canton the spread of the disease continues, but the mortality is lessening.

THE CHOLERA. — With the return of warm weather the cholera has made its reappearance at various centres in Europe. The epidemic which began in April at Lisbon has somewhat abated, and is now officially reported once more not to be cholera. Cases have occurred at various places in Spain, but none are officially admitted, so that early quarantine is much neglected. In France cases have occurred in Finistere since the middle of April and number about four cases a day. In Russia the disease is very widely scattered, and has broken out in many of the provinces. Appearing first in the Polish districts and along the East Prussian border, the disease has attained its greatest severity in the districts of Plozk, Radom and Petrokoff, where the number of cases has already reached several hundred. During the last week there have been reported nearly a hundred cases with twenty-five deaths from Ciechanowice, a town thirty miles from the German frontier. In Warsaw there have been about ten new cases with six deaths each day since the first of May. The disease has appeared at Mislowitz and Stettin and throughout the Vistula district. Many towns in Galicia have been affected, especially Siczerynce and Skala. Turkey, as might be expected, has many centres of infection, none officially recognized. Although the epidemic at Constantinople has been severe, it is now stated to have ceased in that city, and the quarantine has been abolished. Several of the Black Sea ports are now infected.

SMALL-POX QUARANTINE AGAINST STAPLETON, S. I. — Dr. Doty, of the New York Board of Health,

has recommended that a quarantine be established against Stapleton, S. I., for the reason that small-pox is epidemic there, that it is not properly dealt with by the local authorities, and that the conditions in the village constitute a menace to New York City. He urges the Board to act promptly by asking the intervention of the State Board to the end that Stapleton may be cut off from communication with New York.

UNSEEMLY JESTING.—The *Medical Record* makes the following comment on the recent cartoon in *Life* called the "Vivisectionist": "The esteemed contemporary, *Punch*, does not always seem funny at this distance from its proper atmosphere, but it is always good-natured and generally just. Its New York imitator, *Life*, is sometimes neither one nor the other, but simply scurrilous. Its recent cartoon on the 'Vivisectionist' was a loathsome and cowardly performance, utterly false in its representation, mean in its insinuations and low in its intent." As descriptive of the picture, the *Record's* remarks are gentle and its language mild.

THE REGULATION ON THE USE OF OPEN STREET-CARS.—The New York City Board of Health has passed an amendment to the sanitary code, prohibiting the use of open street-cars except from June 1st to October 1st, and directing that during the daytime every fourth car on each line shall be a closed car, and during the night every third car.

HONORARY DEGREES.—At the annual commencement of Princeton College the degree of LL.D. was conferred upon Dr. Alfred A. Woodhull of the Army Medical Corps, and that of A.M. *honoris causa* on Dr. Austin Flint, Jr., of New York. Dr. Landon C. Gray, of New York, was given an honorary A.M. by Columbia College at commencement, June 13th.

DR. BILLINGS'S APPOINTMENT CONFIRMED.—The Senate of the United States, on June 16th, confirmed the appointment of Dr. John S. Billings to be Lieutenant-Colonel and Deputy Surgeon-General of the United States Army.

A NEW PROFESSORSHIP FOR NORTHWESTERN UNIVERSITY.—Dr. William Deering, of Chicago, has given to Northwestern Medical School the sum of \$50,000, to found a professorship to bear the name of Dr. N. S. Davis, who has been a life-long friend of the donor.

RECENT APPOINTMENTS AT JEFFERSON MEDICAL COLLEGE.—At a recent meeting of the Board of Trustees of Jefferson Medical College, Dr. W. Joseph Hearn was elected Clinical Professor of Surgery; Dr. Edward P. Davis, Clinical Professor of Obstetrics; and Dr. S. MacCuen Smith, Clinical Professor of Otolaryngology.

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—The Forty-third Meeting of the American Association for the Advancement of Science will be held in Brooklyn, N. Y., from August 15 to 24, 1894, under the presidency of Dr. Daniel G. Brinton.

DR. LANPHEAR'S REMOVAL TO ST. LOUIS.—Dr. Emory Lanphear has resigned the chair of Operative and Clinical Surgery in the Kansas City Medical College to become Professor of Surgery in the St. Louis College of Physicians and Surgeons.

A NEW DEPARTURE IN MEDICAL LITERATURE.—The first number of *Teratologia*, a new medical quarterly, has just been issued in Edinburgh, under the editorship of Dr. J. W. Ballantyne. Its pages will be devoted exclusively to the subject of antenatal pathology.

PROFESSOR CZERNY AND THE PROFESSORSHIP OF SURGERY AT VIENNA.—Professor Czerny is reported to have refused to be made Professor of Surgery at Vienna because of the inadequacy of the laboratory equipment of the hospital.

"BIRTHDAY" KNIGHTHOOD FOR PHYSICIANS.—In the distribution of honors on her seventy-fifth birthday, Queen Victoria conferred knighthood upon Dr. J. C. Bucknill, F.R.C.P., F.R.S., Mr. F. S. Haden, F.R.C.S., and Dr. T. Grainger Stewart, F.R.C.P., Edin., Professor of Physics in the University of Edinburgh. Of these and several others, Dr. Stewart's is said to be the only one purely medical in origin.

MAGISTRACY, MEDICINE AND MALINGERING.—The special usefulness of a medical magistrate is reported from England. A workhouse inmate was arraigned before a medical J.P., charged with refusing to work, to which he pleaded that he was a victim of heart disease, whereupon the magistrate promptly descended from the bench, produced a stethoscope, auscultated the culprit, and re-ascending the throne of justice, sent him "up" for seven days for malingering.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—During the week ending at noon, June 20, 1894, there were reported to the Board of Health of Boston, the following numbers of cases of acute infectious diseases: diphtheria 43, scarlet fever 59, measles 12, typhoid fever 9.

HARVARD MEDICAL ALUMNI ASSOCIATION DINNER.—The fourth annual dinner of the Harvard Medical Alumni Association will be held at the Hotel Vendome on Tuesday, June 26th, at one P. M. The guests will be Dr. W. M. Polk, of New York, Dr. W. W. Keen, of Philadelphia, Dr. William Osler, of Baltimore, and Deputy Surgeon-General John S. Billings, of Washington.

COLLEGE OF PHYSICIANS AND SURGEONS.—The commencement exercises of the College of Physicians and Surgeons of Boston were held in the Y. M. C. A. Hall on Wednesday afternoon, June 20th.

A LABORATORY COURSE IN BACTERIOLOGY AT THE YALE MEDICAL SCHOOL.—A six-weeks' course in bacteriology is to be given at the Yale Medical School commencing June 20th.

THE MAINE MEDICAL ASSOCIATION.—The Maine Medical Association held its annual meeting at Portland, last week.

NEW YORK.

MORTALITY.—The recent hot weather has had the effect of augmenting to some extent the weekly mortality of the city. During the week ending June 16th there were reported 841 deaths, which represents an annual death-rate of 22.45 per thousand of the estimated population; an increase of nearly three per cent. over the previous week. The principal increase was in diarrhoeal diseases, and there were also three deaths by sunstroke.

COLUMBIA COLLEGE COMMENCEMENT.—On June 18th the annual commencement of Columbia College was held at Carnegie Music Hall, and the degree of M.D. was conferred upon 120 graduates of the Medical Department, the College of Physicians and Surgeons. The Hippocratic oath was administered to the class by Dr. James W. McLane, the President of the latter. The alumni fellowship in anatomy was awarded to Dr. F. J. Brockway, in physiology to Dr. R. J. Cunningham, and in pathology to Dr. W. S. Stone; and Dr. Ira T. Van Giesen received the Alonzo Clark scholarship. The degree of A.M. was conferred upon Dr. Landon Carter Gray.

STERILIZED MILK FOR THE POOR.—Mr. Nathan Strauss has been enlarging the field of his depots for the supply of sterilized milk and other food for infants and young children at the lowest possible prices by issuing blanks, (which have been distributed to the police stations and dispensaries) which, when signed by any reputable physician, will enable parents, too poor to pay at all, to secure these supplies free of charge. In addition, he has secured permission from the Park Commissioners to have pure milk sold at the low rate of one cent a glass in the various parks of the city.

DEATH OF A PHYSICIAN FROM DRUGS AND SEPTICÆMIA.—A physician, Dr. Frank W. Carmon, thirty-five years of age, recently fell a victim to his inordinate craze for drugs. It is stated that he had long been a great sufferer from rheumatism, and in order to relieve the pain used morphia freely, and became addicted to the opium habit. After a time he also took larger quantities of chloral, paralydehyde and other hypnotics, and a few days before he died, he is said to have swallowed about an ounce and a quarter of paralydehyde at a single dose. Yet the next day he had sufficiently recovered from its effect to go out. It was at first supposed that he had died of morphia poisoning, but the coroner's investigation showed that death was in reality due to septicæmia resulting from the excessive use of the hypodermic syringe. Both the arms, from the shoulders to the wrists, were in a state of violent inflammation. Dr. E. R. Squibb, of Brooklyn, mentions a case reported by Dr. T. Mackenzie, of Douglas, Isle of Man, in which a patient recovered, after thirty-four hours of sleep, from a dose of three and a half ounces of paralydehyde.

Miscellany.

THE INFLUENCE OF ODORS ON THE VOICE.

THE subject of smells seems at present to be most passionately studied by French writers. We have recently been shown the psychological influence of smells on character and morals, as evidenced by M. Zola; and now another writer, M. Joal, has published a volume upon "Odors and their Influence on the Voice." That various odors may affect the voice is well known among singers, who consider the violet to be especially detrimental to a clear voice. A story is told of an envious soprano who sent her unsuspecting rival a large corsage bouquet of violets, and thereby caused her failure in a brilliant part. Now M. Joal rejects the idea that the odor of violets prevents a free vibration of vocal cords, which are unaffected by roses. "It is not a property of any particular perfume, but is wholly a question of individual susceptibility. One person may be unaffected by flowers, musk, civet or various toilet perfumes, but becomes at once hoarse and oppressed on perceiving the odors of oils or fats.

"It is difficult to offer any explanation of these vagaries which we must be content to call olfactory idiosyncrasies. There is no doubt, however, that odors may cause vocal disturbances, especially in persons of nervous temperament."

ST. LOUIS AND ITS MEDICAL SCHOOL.¹

PROFESSOR W. S. CHAPLIN, Chancellor of Washington University, St. Louis, in a recent address, gave the following explanation of the present condition of medical education in St. Louis:

"Don't think for a minute that these many medical schools in the West have been established for purely pecuniary reasons. The doctors do not make enough out of them certainly to pay for the work which they put into them. They might make more money, probably, by sawing wood the same amount of time. They do it in order to establish themselves as specialists. They have no other reason. Is this not a case where you have put on too much restriction in one direction? And that has produced an abnormal growth in another direction. If you look into the history of these medical schools, you find that there was a time when there was but one medical school. Some fifty years back, in St. Louis, I believe, there was just one. Then, by a process which the naturalists understand perfectly, by the growth of a kind of septum across the medical school, suddenly there were two medical schools, equipped fully, and those two medical schools were running in the most violent opposition. Here, in the East, I understand the medical profession have none of these differences and troubles, but in the West every medical school means a new set of mutual admirers. The professor of ophthalmology sends all his cases of surgery to the surgeon who is connected with his medical school. Go into St. Louis to-day, and you find just eleven sets of men who generally recommend and send all their patients to the men connected with their own schools. I do not despair of medical education in the West. I hope there will be constant and rapid deaths among the medical schools. The condition is certainly a disgusting one when viewed from the point of education."

[Special Correspondence.]

LETTER FROM SAN FRANCISCO.

ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

SAN FRANCISCO, June 11, 1894.

MR. EDITOR:—The American Medical Association has had its meeting and adjourned, or as the daily papers here express it, "The Medicos have gone and Odd Fellows' Hall no longer shivers with the echoes of comminuted fractures and the creaking of tubercular joints."

The regular reports of the meeting you have already had. While living quietly on milk and seltzer and thinking of the gastronomic glories of the recent past, it occurred to me that your readers might enjoy a bit of gossip about the social side of the convention. It was extremely social! The hospitality was generous and constant, and even when making allowance for Californian fondness for florid expression, the newspaper accounts were but just.

The first "feast and frolic" was a banquet tendered the American Medical Editors Association by Mr. R. E. Queen, on Monday evening, before the Congress met. Nearly two hundred guests were present. Dr. I. N. Love acted as toast-master, while Dr. Hughes made his usual speech to his "fellow cranks." The papers reported that "it was long after midnight when the last 'cat died,' and although the electric lights were out for a few minutes, neither the brilliancy of the wit nor the sparkle of conversation was dimmed for one moment."

The same evening a reception was held by the Committee of Arrangements in the Rotunda of the Palace Hotel.

On Tuesday evening occurred the great reception of the San Francisco County Medical Society. I quote: "Over five hundred ladies and gentlemen, nearly all of whom appeared in full evening dress, were present. The ladies, without exception, appeared in elegant toilets, lending to the scene charming grace and vivacity. The greater number were visitors from the East, and all expressed themselves in the highest terms of praise at the magnificent reception tendered them. Refreshments were served at ten o'clock. Liquid refreshments were served at the buffet in the vestibule throughout the entire evening."

On Wednesday evening Dr. W. F. McNutt entertained the Association with great hospitality. About six hundred persons were present. "Many, after paying their respects to the host and hostess and strolling around engaging in social converse, departed, but the majority remained and partook of the generous hospitality extended to the fullest extent. The toilets of the ladies present were elegant in every respect, and were only rivalled by the beauty and vivacity of the wearers of them."

The same evening a large reception was given by Dr. L. C. Lane at the new hospital of the Cooper Medical College; and it is probable that those who left Dr. McNutt's before supper were more eager to taste the bounties offered them at the College.

The ladies were given afternoon lunches and entertainments by Mrs. McLean and Mrs. Lane, and by Mr. Sutro at Sutro Heights, where they had an opportunity to see the "most sublime view in the world."

Many of the sections had dinners of their own; and the Obstetrical Section was banqueted by the Gynecological Society of San Francisco. Besides those already mentioned there were several private dinners. The meeting of the Medical Temperance Association, which was held on Thursday, was not largely attended.

The numerous boat-rides and excursions, the visits to the Mid-Winter Fair, and other attractions of the neighborhood—though tempting to the casual visitor—I did not attend. What little time was left from the sessions and the dinners was required for rest and gastric repose. Certainly the thousand guests of this Golden City of the West have reason to remember a most generous hospitality and welcome.

Yours truly,

S. F.

A QUALIFIED SIGNATURE TO THE REGISTRATION LAW.

BOSTON, June 18, 1894.

MR. EDITOR:—For any members of the State Society who do not wish to ignore their "license to practise," given to members by the act of incorporation, perhaps, as the present law reads, the best phrase, over their signature of registration, would be this, *reserving the claim of a right to practise, irrespective of registration*. Thus, it would seem, no one need have any objection to registering.

Yours very truly, J. L. W.

THE MEDICAL REGISTRATION LAW.

BOSTON, June 14, 1894.

MR. EDITOR:—A law, as now enacted by the General Court, which calls upon medical graduates of Harvard University, and others already legally licensed, and upon members of a medical society authorized to license, whose charter has not yet been repealed (if indeed it can be without its own consent), while it expressly excepts certain noted quacks and persons who practise "cosmopathic or any other method of healing"—such a law, some of us, young and old, are inclined to think a little *too utter* for an intelligent community. A clause above is italicized because it would seem to let in the whole crowd,—regulars, irregulars, one and all.

I suppose any one classed as a healer of any other method, may be entitled to subscribe himself,

Yours to register as, H. O. A. O. M. O. H.

¹ Thanks to Dr. Gay for his authoritative adoption of "practiser," the simple and correct form—"practitioner" being "an unlovely intruder." See "Words and Their Uses," by Richard Grant White, page 216.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, JUNE 9, 1894.

Cities.	Estimated population.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from

Deaths reported 1,899; under five years of age 716; principal infectious diseases (small-pox, measles, diphtheria and croup,

diarrhoeal diseases, whooping-cough, erysipelas and fever) 327, acute lung diseases 245, consumption 229, diphtheria and croup 126, diarrhoeal diseases 73, scarlet fever 33, measles 23, whooping-cough 23, erysipelas 13, typhoid fever 13, small-pox 10, cerebro-spinal meningitis 8.

From measles Brooklyn 10, Cleveland 7, New York 6. From whooping-cough Brooklyn 7, New York 5, Washington, Cincinnati and Cleveland 3 each, Boston 2. From typhoid fever Brooklyn, Washington, Cincinnati and Nashville 2 each, New York, Cleveland, Lowell, Somerville and New Bedford 1 each. From small-pox New York 7, Brooklyn 2. From cerebro-spinal meningitis New York and Lawrence 2 each, Washington, Worcester, Lowell and Lynn 1 each. From malarial fever Brooklyn 7, New York 3, North Adams 1.

In the thirty-three greater towns of England and Wales with an estimated population of 10,458,412, for the week ending June 2d, the death-rate was 17.0. Deaths reported 3,403: acute diseases of the respiratory organs (London) 222, measles 240, whooping-cough 112, diphtheria 53, scarlet fever 40, diarrhoea 36, fever 26, small-pox (London 4, West Ham and Birmingham 3 each, Liverpool and Bradford 1 each) 12.

The death-rates ranged from 13.6 in Bristol to 30.0 in Wolverhampton; Birmingham 17.2, Bradford 16.8, Cardiff 18.9, Gateshead 17.3, Hull 14.0, Leeds 17.4, Leicester 13.8, Liverpool 20.0, London 16.4, Manchester 19.6, Newcastle-on-Tyne 16.8, Norwich 18.8, Nottingham 19.4, Portsmouth 14.6, Preston 13.6, Sheffield 16.3, Sunderland 20.3.

METEOROLOGICAL RECORD.

For the week ending June 9th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 9, 1894, TO JUNE 15, 1894.

FIRST-LIEUT. DRANE C. HOWARD, assistant surgeon, is relieved from duty at Fort Buford, North Dakota, and will report in person to the commanding officer, Fort Snelling, Minnesota, for duty at that station.

The following named officers, having been found by Army retiring boards incapacitated for active service on account of disability incident to the service, are, by direction of the President, retired from active service: LIEUT.-COL. SAMUEL M. HORTON, deputy surgeon-general; CAPTAIN MARCUS E. TAYLOR, assistant surgeon; CAPTAIN WILLIAM G. SPENCER, assistant surgeon.

PROMOTIONS.

FIRST-LIEUTS. PHILIP G. WALES and BENJAMIN L. TEN EYCK, assistant surgeons, to be assistant surgeons with the rank of Captain, June 7, 1894, after five years' service, in conformity with the act of June 23, 1874.

APPOINTMENTS.

DRS. J. G. MUMFORD, W. A. BROOKS and C. A. PORTER have been appointed surgeons to out-patients at the Massachusetts General Hospital.

RECENT DEATHS.

JAMES EDWIN WALKER, M.D., M.M.S.S., died in Brookline, Mass., June 15, 1894, aged sixty-two years.

DR. MIDDLETON MICHEL, of Charleston, S. C., died in that city, June 4th, aged seventy-two years. He was a graduate of the Medical College of South Carolina and at one time Associate Editor of the *Charleston Medical Journal*.

ELIJAH S. ELDER, M.D., President-elect of the Indiana State

Medical Society, died in Indianapolis, May 19th, aged fifty-three years. He was a graduate of the Medical College of Ohio and of Bellevue Hospital Medical College. In 1890 he was chosen Dean of the Medical College of Indiana.

AUGUST KUNDT, Director of the Physical Institute of the University of Berlin and the successor of Von Helmholtz, died recently, aged fifty-five years.

DR. WILLIAM FROST CUNNINGHAM, formerly of Charlestown, died in Leamington, England, June 5th, aged thirty-five years. He was a graduate of the Harvard Medical School, class of 1881.

DR. SPERK, the Director of the Imperial Institute of Experimental Medicine in St. Petersburg and a syphilologist and dermatologist of high repute, died recently. For twenty-one years he was chief physician to the Kalinkin Hospital in St. Petersburg. His best known works are those on "Prostitution and Prostitutes."

BOOKS AND PAMPHLETS RECEIVED.

A Contribution to the Study of the Physiological Actions of Sparteine. By David Cerna, M.D., Ph.D. Reprint. 1894.

Myxodema, Acquired and Congenital, and the Use of the Thyroid Extract. By George W. Crary, M.D., of New York. Reprint. 1894.

Brain Surgery, with Report of Nine Cases. Surgical Clinic, given at Wesley Hospital, March 31, 1894. By F. C. Schaefer, M.D. Reprints. 1893-94.

De l'Hydronephrose Intermittente. Par le Docteur Lucas-Championnière, Chirurgien de l'hôpital Saint-Louis. Paris: Coccoz, Libraire-Editeur. 1892.

A Case of Primary Tuberculosis of the Laminæ and Spinous Processes of the Vertebral Column. By John B. Roberts, M.D., of Philadelphia. Reprint. 1894.

Tumor of the Brain Simulating a Vascular Lesion; to which is added an Account of the Autopsy, with Remarks. By J. T. Eskridge, M.D., of Denver, Col. Reprint. 1894.

Recent Studies in Naupathia, or Seasickness, Symptomatology, Diagnosis, Pathogenesis and Treatment by a New and Efficacious Method. By Winslow Warner Skinner, M.D. (Par.) Reprint. 1894.

Sur la Cure Radicale des Hernies. Série Nouvelle de 116 Cas, Complétant un Total de 391 Cas, Mémoire présenté à l'Association pour l'avancement des Sciences à Besançon. Par le Dr. Just Lucas-Championnière. Paris: Coccoz, Libraire-Editeur. Reprint. 1894.

Zur Lehre von der Entwicklung des Beckens und Seiner Geschlechtlichen Differenzierung. Inaugural-Dissertation zur Erlangung der Doctorwürde einer Hohen Medicinischen Facultät der Universität Bern. Vorgelegt von Moses Konikow, Aus Zarizin (Russland). Reprint. 1893.

Surgical Shock. Procidencia Uteri. Profuse Menstruation. The Perfect Needle-Holder. A New Uterine Curetting Forceps. Acute Puerperal Cellulitis and True Pelvic Abscess. A New Method of Examining the Kidney, Especially for Stone. By Charles P. Noble, M.D., Philadelphia. Reprints. 1894.

Practical Lectures on Dermatology, Comprising a Course of Fifteen Lectures delivered at the University of Vermont Medical Department, during the session of 1892-93. By Condict W. Cutler, M.S., M.D., Professor of Dermatology, University of Vermont Medical Department, etc. New York: G. P. Putnam's Sons. 1894.

Rotura de la Uretra por Estrecheces; Abceso Urinario y Gangrena del Escroto; Pérdida de Cinco Centímetros de Uretra; Uretrotomía Interna, por la Electrolisis—Curación. Por el Dr. Ramon Martín Fil, Médico-director del Hospital Noble de Málaga. Barcelona: Establecimiento Tipográfico de Amat y Martínez. Reprint. 1894.

Further Remarks on the Occurrence of a Form of Non-Albuminous Nephritis other than Typical Fibroid Kidney. A Serious Fallacy Attending the Employment of Certain Delicate Tests for the Detection of Serum-Albumin in the Urine, Especially the Trichloroacetic Acid Test. By D. D. Stewart, M.D., Philadelphia. Reprints. 1894.

Pathological Notes on Two Pedunculated Tumors. Three Specimens of Tumors of the Heart: Metastatic Carcinomatous Nodule in the Myocardium; Implantation Sarcoma of the Right Ventricle; Primary Round-Cell Sarcoma of the Epicardium. A Specimen of Four Healed, Ascending, Ileal Invaginations, Symmetrical and Equidistant. By Ludvig Hektoen, M.D., of Chicago. Reprints. 1893.

The Relation of the Patellar Tendon-Reflex to some of the Ocular Reflexes found in General Paralysis of the Insane. A Series of Wools for the Ready Detection of "Color Blindness." Clinical History of a Case of Spindle-Cell Sarcoma of the Choroid, with a Study of the Microscopic Condition of the Growth. By Charles A. Oliver, M.D., of Philadelphia, Pa. Reprints. 1893.

Address.**THE LEGISLATIVE CONTROL OF MEDICAL PRACTICE.¹**

BY REGINALD H. FITZ, M.D., BOSTON.

(Continued from No. 25, p. 613.)

THUS, at the present time, there are laws intended to regulate the practice of medicine to a greater or less extent in all the States of the Union, except in Massachusetts and New Hampshire.

The requirements of these laws vary within very wide limits. Rhode Island merely demands that the name and residence shall be recorded in the town clerk's office. In Maine and Wisconsin the physician cannot recover compensation unless he has a medical degree from a public medical institution in the United States, or a license from the State Medical Association, or, in Maine, a certificate of good moral character from the town authorities. The simple registration of the diploma or license suffices in Arizona, the District of Columbia, Georgia, Idaho, Indiana, Kentucky, Louisiana, Michigan, Nebraska, Nevada, South Carolina, South Dakota, and Wyoming. The possession of a diploma or a certificate of qualification from a State or County Medical Society is sufficient in Kansas and Ohio.

The diploma must be verified by boards of examiners in California, Colorado, Connecticut, Delaware, Iowa, Montana, New Mexico, Oregon, South Carolina, Tennessee, Vermont; by boards of health in Illinois, Kentucky, Louisiana, Missouri, Nebraska, Oklahoma, South Dakota, West Virginia. They are only approved when representing certain periods of study in Maryland, Minnesota, Montana, Nebraska, New York, New Jersey and North Dakota.

Candidates who have no diploma are required to pass an examination in Alabama, Arkansas, Colorado, Connecticut, Delaware, Missouri, Montana, New Mexico, North Carolina, Oklahoma, Illinois, Iowa, Oregon, Tennessee, Texas, Utah, Vermont, Virginia, West Virginia.

Examinations are the sole qualification for license in Florida, Maryland, Minnesota, Mississippi, New Jersey, New York, North Carolina (except for graduates prior to 1880), North Dakota, Pennsylvania, Utah, Virginia and Washington.

The effect of these laws also is extremely various. In Arkansas, California, Florida, Georgia, Ohio, South Carolina and Texas the laws are said to be either unworthy of the name, contain glaring defects, are of low standard, unsatisfactory or practically inoperative. Even in North Carolina the law is defied with impunity. On the contrary in Alabama, Minnesota and Virginia, the laws are almost ideally perfect. In New York the promise has been more than fulfilled. More and more support is being given to the law in West Virginia, while in Illinois, Indiana, Iowa, Kentucky and Missouri the laws are efficient, salutary, working well, or meeting with general favor. In New York the number of physicians entering practice has been diminished, and the quality has been improved. Of 327 candidates in 1892, 267 fulfilled the requirements, of whom 244 were regulars, 17 homœopaths and six eclectics. In Indiana 559 practitioners left the State;

in Kentucky 400 or 500, and 250 in Minnesota, during the year 1885.

A conspicuous effect of these laws has been seen in the improvement of the standard of medical education. To them, more than to any one cause, is due the difference which exists between the condition now and in 1870. In Alabama, Colorado, Connecticut, Illinois, Nebraska, Oregon, South Dakota and Washington, at least three full courses of five to six months each, no two in the same year, are demanded. The State of Oregon, after 1898, will require four courses of six months each from physicians who wish to practise in that State. There is not only a prolongation of the period of study as the effect of these laws, but there is also an increased demand for a preliminary education, the establishment of new professorships, and more exacting examinations for the degree. Of all agents distinctly bringing about this change, the Illinois State Board of Health, and especially its secretary, the late Dr. John H. Rauch, deserve the highest consideration.

Let us now consider the recent efforts in Massachusetts. In the address, previously referred to (p. 611), it is stated that all laws relating to the licensing of physicians by the State of Massachusetts were stricken from the statutes in 1859. The influence of the homœopaths in bringing about this result was obvious, but a number of them still retained their membership in our Society. They were inoffensive, but the feeling against homœopathy was so strong in the minds of certain members that, in 1870, a protest was made by some of the latter against the admission to the American Medical Association, then meeting in Washington, of delegates from the Massachusetts Medical Society. The Association voted, in effect, "that the Massachusetts Medical Society voluntarily and improperly furnishes shelter and gives countenance to irregular practitioners to such an extent as to render it unworthy of representation in the General Assembly of American Physicians."⁴³

At the annual meeting of our Society, May 24, 1870, the following vote, "amid much confusion," was passed:

"Resolved, That the Massachusetts Medical Society hereby expels from fellowship all those who publicly profess to practise in accordance with any exclusive dogma, whether calling themselves homœopaths, hydropaths, eclectics, or what not, in violation of the code of ethics of the American Medical Association."⁴⁴

This vote, however, had no legal force, since no member could be expelled except after a trial in conformity with the by-laws. But Dr. Cotting, at the Councillor's meeting, June 6th, 1871, offered the following preamble and resolutions, which were adopted by the Council, and on the following day by the Society:

"Whereas, The Massachusetts Medical Society has always endeavored to make, as its charter emphatically enjoins, 'a just discrimination between such as are duly educated and properly qualified for the duties of their profession and those who may ignorantly and wickedly administer medicine,' while at the same time it has ever acted in accordance with the 'liberal principles' of its foundation, and shows itself ready to examine and to adopt every suggestion, from whatever source, promising improvement in the knowledge and treatment of disease;

¹ The Annual Discourse before the Massachusetts Medical Society delivered June 13, 1894.

⁴³ Proc. Mass. Med. Soc., 1871, 204.

⁴⁴ Loc. cit., 1870, 159.

"And, whereas, It is alleged that some of its Fellows, in opposition to the spirit and intent of its organization, consort, in other societies or elsewhere, with those whose acts tend 'to disorganize or to destroy' the Society;

"Therefore, resolved, That if any Fellow of the Massachusetts Medical Society shall be or shall become a member of any society which adopts as its principle in the treatment of disease any exclusive theory or dogma (as, for example, those specified in Art. I. of the By-laws of this Society), or himself shall practise, or profess to practise, or shall aid or abet any person or persons practising, or professing to practise according to any such theory or dogma, he shall be declared to have violated the By-laws of the Massachusetts Medical Society by 'conduct unbecoming and unworthy an honorable physician and member of this Society.' By-laws, VII., § 5.

"Resolved, In case the Society concur with the Councillors in the foregoing resolution, that the President of the Society shall appoint a committee of five Fellows (to hold office one year and until others are appointed) to bring before a Board of Trial any Fellow who, three months from this date or after, shall be found chargeable with the offence set forth in the foregoing resolution.

"Resolved, That, after concurrence by the Society, the foregoing preamble and resolutions shall be printed, and a copy sent to every Fellow of the Massachusetts Medical Society.

"Resolved, That a committee of three be appointed by the chair to report the action of the Councillors on the foregoing preamble and resolutions to the Society, to-morrow, for concurrence."⁴⁵

A board of trial was appointed; it reported in 1873, 1875 and in 1877, in each of which years a certain number of the homœopathic members were expelled until all were thus disposed of.

In the meantime, as already stated, successful efforts were being made to secure the legislative control of medical practice in various States. Their success depended upon the recognition of the principle that no attempt should be made to interfere with the chartered rights of existing medical societies. The action of our Society towards its homœopathic members was based on the view that their "conduct was unbecoming and unworthy an honorable physician." It, therefore, could not, then, consistently unite with the homœopathic society in favoring a law which should place both on the same level.

But the need of discriminating between educated and honorable physicians and the reverse was strongly felt by individual members of the Society, and the earlier attempts at securing legislation were initiated by them.

In 1877 a bill⁴⁶ was introduced by Mr. Ewing of Hampden, and was entitled "An Act to regulate the Practice of Medicine and Surgery in the State of Massachusetts." It provided that each and every existing chartered medical society shall elect censors, with authority to examine and license practitioners of medicine, surgery and midwifery. The license was to be valid for a year only, and was to be furnished on presentation of a medical diploma or satisfactory certificate of examination from an authorized board. The certificate of license was to be recorded by the county clerk, and might be revoked for cause. The penalty of practising without a certificate was from \$50.00 to \$100.00 for the first offence, from \$100.00 to \$400.00 for any subsequent offence, and fees for services rendered could not be collected by law.

This bill was intended to prevent the practice of

medicine by uneducated persons, without, however, establishing any common or definite standard, and required merely the verification of certificates. It was referred to the Committee on the Judiciary, who reported against the bill,⁴⁷ and it was rejected. A month later another bill, relating to medicine and pharmacy, was presented, and was referred to the next General Court.⁴⁸

In the following year the same bill was again brought before the Senate,⁴⁹ and was referred to the Committee on Water-Supply and Drainage. They reported, February 20, 1878, that it ought not to pass, and it was rejected. A similar bill⁵⁰ "to regulate the Practice of Medicine and Surgery in the City of Boston" was also referred to the Committee on Water-Supply and Drainage. The clause relating to the inability to collect fees by law was omitted. It was expressly stated that veterinary surgeons, exclusive practitioners of the Thomsonian or botanic system of medicine, clairvoyants or healing mediums, not assuming the title of doctor, physician, surgeon or midwife, persons practising gratuitously, and those not occupying an office or place of business for the practice or advertisement of medicine, surgery or midwifery in the city of Boston, were exempt from its provisions.

The practical effect of this bill was to limit the use of the title of doctor, physician, surgeon or midwife to persons of some degree of education, but the difference in standard might be extreme. It was less restricting than its predecessor. The committee reported leave to withdraw, but a minority recommended its passage. This bill also appears as House, No. 122, submitted in reply to a petition from the mayor of Boston, for an order relative to regulating the practice of medicine and pharmacy in the city of Boston. The same minority, as before, of the Committee on Water-Supply and Drainage, recommended its passage, but leave to withdraw was voted, March 15, 1878.

In 1880, Governor Long, in his inaugural address, stated that the necessity of protecting the community against medical impostors had been urged upon his attention, and he referred it to that of the legislature. At this time the health department of the American Social Science Association had its headquarters in Boston, and a number of the younger Fellows of the Massachusetts Medical Society were among its members. Through their initiative, a powerful effort was made in the name of the above association to secure a law to regulate medical practice. Dr. E. W. Cushing, of Boston, at a meeting of the Suffolk District Medical Society early in the year, explained⁵¹ the steps which had been taken and the provisions of the bill. He stated that it had been prepared after consultation with eminent lawyers and representative physicians. The experience of other States had been utilized in its preparation, and the final draft met with the approval of the leaders of the homœopathic and eclectic medical societies. It was supported by eminent citizens of Massachusetts in Boston and elsewhere. It provided for the appointment, by the Governor and Council, of a board of medical registration composed of eight physicians and one dentist. The former were to be selected from the incorporated medical societies of the State in proportion to the whole number of members

in each. This board was to examine, in medical subjects exclusive of therapeutics, applicants for a license to practise medicine, dentistry or midwifery. All members of the State medical societies incorporated at the time of the passage of the act were to be exempt from examination. Also all practitioners in the State, of one year's standing, having an approved diploma or license; all practitioners of good moral character and reputation having practised in the State for ten consecutive years; non-resident practitioners with an approved degree or license, and students of incorporated schools rendering gratuitous services. Licenses could be refused or revoked for cause. The penalty for practising without a license was a fine not exceeding five hundred dollars.

This bill was referred to the Committee on Public Health, which held six hearings, and reported "An Act relating to Practitioners of Medicine,"⁵³ providing that persons offering or advertising to practise medicine, surgery or midwifery, without a reasonable degree of learning, skill and diligence therein, shall be fined not exceeding five hundred dollars. Another provision was that persons professing to heal or cure disease in whatever manner, shall not assume the title of doctor, or of doctor of medicine, without having received the degree of doctor of medicine from a reputable chartered medical institution, under penalty of a fine not exceeding five hundred dollars. There were exempt from this provision persons who had used the title for ten years in the State, and members of any medical society of the State lawfully exercising the power to examine and approve its members before admission.

The bill was rejected by a very large majority in the House. This attempt of the Social Science Association to protect the community against medical impostors was defeated, according to Dr. Granger,⁵⁴ largely because of counter-petitions and complaints that the law was intolerant and exclusive, for the benefit of the few, and an interference with the rights of the many. The opposition was determined and powerful. It comprised some of the oldest and most honored physicians, many educated and intelligent citizens, all the quacks and their friends, and was supported by many newspapers, and advocated by eminent counsel.

In 1882, Governor Long, in his veto of the bill to "regulate the practice of dentistry," stated: "It would perhaps be better worth while to consider the expediency of a general statute to the effect that any person pursuing a business or profession without sufficient skill therein shall be punished. Such a statute, in the hands of judge and jury, would never work injustice, and yet would be ample for those exceptional cases of imposition, on the strength of which vicious special statutes are urged from year to year."

This suggestion from Governor Long was in harmony with the provision of the bill of 1880. It was eminently necessary in the practice of medicine, since at that time, the ruling of Chief Justice Parsons in the case of the Commonwealth v. Samuel Thomson was generally held to be sound law. As has already been stated,⁵⁵ this ruling was replaced in 1884 by that of Judge Holmes. It was urged by Mr. Benton, in his argument before the Committee on Public Health

in 1885, against the petition of the Massachusetts Medical Society for a law to regulate the practice of medicine, that the latter decision made further legislation unnecessary. He says:

"The present law is clear and ample. A man or woman who assumes to practise the healing art impliedly contracts that he or she has sufficient skill and knowledge to do the thing which they assume to do, to cure the disease which they assume to treat, and no other. And if he or she does not have it, they are liable in damages for all the consequences that result from the lack of knowledge and skill. If he or she is grossly or presumptuously ignorant and negligent, and a person is thereby killed or injured, he or she is liable for manslaughter or for assault."

Even with this interpretation of the law, the security to the public is insufficient. As has already been shown, the cases of imposition are not so exceptional as assumed by Governor Long, neither is the victim nor his or her friends always conscious of it or competent to judge of the skill or knowledge of the medical adviser. None are more aware of the defenceless state of the public in these respects than physicians.

The next attempt was made in the name of our Society. In June, 1884, on motion of Dr. H. O. Marcy, it was voted⁵⁶ that a committee be appointed by the President of the Massachusetts Medical Society to secure, if possible, an act to protect the people from ignorant and incompetent practitioners of medicine. A committee of sixteen was appointed, Dr. Townsend, of Natick, being the chairman. This committee was subsequently strengthened by the addition of Drs. G. C. Shattuck, Cotting, Lyman, H. W. Williams and Hosmer, as a special committee to aid that of the Society in its petition.

A hearing was given, lasting four days, was largely attended, and excited much public interest. It was shown as probable that there was in Boston, at the time, "greater ignorance and criminality, disguised under the name of the profession, than in any other city of the Union. Even houses of ill-fame are covered under the name of a physician."⁵⁷

The committee reported⁵⁷ June 3, 1885, "An Act to regulate the Practice of Medicine," but one member dissenting. It provided for a board of nine examiners, not more than four to belong to the same medical society or school of medicine, who were to register as qualified physicians all graduates of legally chartered medical colleges or universities having the power to confer degrees; also all practitioners of medicine of ten years' continuous practice in the State. All other applicants for registration were to be examined, and at the close of a year all applicants whatsoever were to be examined. The examination was to be elementary and practical, and to embrace the subjects of anatomy, surgery, physiology, chemistry, pathology, obstetrics and the practice of medicine, exclusive of therapeutics. Persons practising medicine or surgery without being registered were liable to a fine of not less than fifty nor more than five hundred dollars.

The bill was refused a third reading in the House by an overwhelming majority. According to the *Boston Medical and Surgical Journal*,⁵⁸ despite the origin of the movement at the annual meeting of the

Society, and its advocacy, both by a general and special committee, "the sentiment of the great majority of the Society was one of entire indifference. But a small portion thought it worth while to put themselves on record at all."

Dunglison and Marcy state: "It was presented during the last hours of a heated, long drawn out political contest, when time could not be given for its proper consideration, and, loaded down with amendments offered for its destruction, it failed of passage."

Four years later the attention of the legislature was again called to this subject through the labors of Dr. J. Frank Perry, at the time editor of the *Journal of Health*. The draft of the bill then presented⁶⁰ required that licenses to practise should be given by the Board of Health to medical graduates of legally chartered colleges, to members of at least one year's standing of incorporated medical societies, and to practitioners who had been in practice for ten years. All other applicants were to be examined by the censors either of the Massachusetts Medical Society, the Homœopathic Medical Society or the Eclectic Medical Society, and the Board of Health was to license the successful candidates. Violation of the law was punishable with a fine not exceeding \$500.00, or imprisonment not exceeding six months. Three petitions were presented in favor of the object of this bill, and twenty-six against it.

The subject was referred to the Committee on the Judiciary, who reported, May 23, 1889, a bill⁶¹ entitled "An Act to Regulate the Practice of Medicine and Surgery." It provided that practitioners should file an affidavit of their qualifications with the city or town clerk, who should give a certificate stating the substance of the facts set forth in the affidavit, which certificate was to be conspicuously displayed in the practitioner's office. Violation of the provisions of this act was to be punished by a fine not exceeding one thousand dollars, or imprisonment not exceeding one year, or by both fine and imprisonment.

This bill was sent up for concurrence by a vote of eighty-two to fifty-nine, and was defeated in the Senate. Dr. Perry informs me that he used every effort to defeat this bill in the Senate, since he was determined to obtain a good bill or none at all.

In 1890 the attention of the legislature was again called to the subject by Dr. George S. Wilson, of Boston, representing the Working People's Aid Society, and other workingmen's organizations. The matter was referred to the Committee on the Judiciary, who reported it inexpedient to legislate.

In the following year Dr. Wilson succeeded in obtaining a hearing before the Committee on Public Health, and presented the draft of a bill "to establish the registration of Medical Degrees." No one was to use the title of "Doctor," or of "Doctor of Medicine," or any abbreviation thereof, unless possessing a diploma from some reputable college or institution legally empowered to confer the degree. At the end of the year, after the passage of the act, no medical college was to be considered reputable which required less than three years of medical study and three annual courses of lectures of not less than twenty weeks each. The penalty was a fine of \$50.00 to \$200.00 for the first offence, and from \$100.00 to \$500.00 for each

subsequent offence, or imprisonment from thirty to ninety days, or both fine and imprisonment.

The committee reported March 24, 1891, a bill⁶² entitled: "An Act to regulate the Practice of Medicine by the Registration of Practitioners," the provisions of which were similar to those of the bill reported in 1889. This bill was returned to the committee, slightly amended, and again reported April 7, 1891.⁶³ Dr. Wilson states that, in his opinion, the bill was so unsatisfactory to the working people, that he "went to the State House and saw several influential members, who succeeded in killing the bill." It was refused a third reading in the House by a vote of eighty-six to forty-two.

In the present year, Governor Greenhalge, in his address to the legislature, makes the following request: "64

"I ask you also to consider the expediency of requiring that practitioners of medicine be registered in somewhat the same manner as pharmacists are now registered. In every State of the Union, except five, such a system of registration has been established, and it cannot fail to protect the public, and at the same time help to maintain a high standard among medical practitioners."

Pharmacists are registered by a board of registration appointed by the Governor and Council. The candidate is examined, receives a certificate, if qualified, and the certificate must be conspicuously displayed in his place of business. Unregistered pharmacists transacting the business of pharmacy are punished by a fine not exceeding fifty dollars.

The above section of the Governor's address, also a bill to regulate the practice of medicine and surgery by the registration of practitioners,⁶⁵ were referred to the Committee on Public Health. They reported, three members dissenting, the bill⁶⁶ "to provide for the Registration of Physicians and Surgeons." This bill was essentially the same as the House bill (No. 445) of 1885, and corresponded very closely with the act of the same year to establish a Board of Registration of Pharmacy. As a substitute for this bill, Senator Kittredge offered another,⁶⁷ which is practically the bill recommended in 1889,⁶⁸ with a smaller penalty and a clause making it a misdemeanor to append, without authority, the letters M.D. to the name of the person. The committee's bill was advocated in the Senate by Dr. Harvey, and was passed to be engrossed; Mr. Kittredge's substitute being defeated by a vote of twenty-two to six. The bill⁶⁹ as passed by the Senate differs from the committee's bill, in containing, as amendments, a clause preventing more than three members of the board being at one time members of any one chartered State medical society; also that practitioners of three years' continuous practice before the passage of the bill should be entitled to registration; also, that all applicants with the degree of M.D. from a legally chartered medical college or university having the power to confer degrees in medicine in this Commonwealth shall be registered in the future without examination.

Finally, the bill was so amended as not to apply "to clairvoyants, or to persons practising hypnotism, magnetic healing, mind cure, massage methods, Christian science, cosmopathic or any other method of

healing," provided such persons do not advertise or hold themselves out by the letters M.D., or the title of doctor, meaning doctor of medicine.

Senator Kittredge claimed that there were four thousand remonstrants against the bill, and none but doctors in its favor.⁷⁰

Some of the opponents of the attempt to secure the legislative control of the practice of medicine in Massachusetts have placed themselves on record in the public press. The personal characteristics of many of those present at the hearings have been thus described:⁷¹

"What a collection of them there was in the Green-room at first, and afterwards in the large hall of the House of Representatives, to which an adjournment was necessary on account of the crowds! Medical blacklegs of all kinds, deceitful clairvoyants, long-haired spiritualists, necromancers, wizards, witches, seers, magnetic healers, pain charmers, big Indian and negro doctors, abortionists, harpies who excite the fears and prey on the 'indiscretions' of the young of both sexes, who treat venereal diseases with the utmost secrecy and despatch, who have good facilities for providing comfortable board for females suffering from any irregularity or obstruction, who sell pills which they are very particular to caution women when pregnant against using; *et id genus omne*. Some of them looked sleek, well fed and prosperous; others seemed to have come from the very slums of destruction. Most of them had a coarse, animal, degraded look."

(To be continued.)

CASES OF TRAUMATIC HEADACHE.¹

BY CHARLES F. FOLSON, M.D.

IN studying the various causes of headache, I have grouped together six similar cases due to traumatism, which I report to-day. Others, where the injury was to the nose, are not included, inasmuch as the cause of the symptoms in them was complex.

CASE I. C. H., aged seventeen years, with healthy antecedents, strong, well developed and nourished, and sensibly brought up, was referred to me in October, 1890, by Dr. Hasket Derby, who had carefully examined his eyes and found them without defect. Four years previous to my seeing him, he was thrown from a horse and struck by the freshly-shod hoof of another horse, over the upper and middle region of the left parietal bone. There was a large irregular cut in the scalp which bled freely and finally healed by granulation. There was no unconsciousness after the accident and there were no cerebral symptoms at that time.

A year later, he began to have headache now and then, which was not severe, but which, still a year later, had become very bad and more frequent. These headaches began just back of the left eye, a couple of inches anterior to the cicatrix, extended over the temporal region, and finally involved the whole head. They lasted several days and were quite disabling. They were not affected in a causative way by the use of the eyes. The headaches became more and more troublesome until the summer of 1890, when they were almost constant, although the boy was at the

time leading an outdoor life on a farm where he was passing his vacation. He made as little as possible of his symptoms, as he was very desirous of returning to school, which he did in October. He was not able to study and was sent back to me by his teacher as being in constant suffering. From his mother, whom I then saw for the first time, I learned that he had been obliged to give up the active occupations and amusements of boyhood, and walked about, and especially up and down stairs, with the greatest care in order to avoid the least jar, which made his head much worse. He could not study or read and there was no let-up to the pain which varied from time to time in degrees of severity. There had never been any convulsions nor vomiting.

Physical examination of the patient was negative, except that over the upper middle part of the left parietal bone there was an irregular cicatrix, quite tender on pressure, about an inch and a quarter long, and three-sixteenths of an inch wide at the widest part. The boy had the general appearance of health, except that his face usually had the expression of pain. He was unnaturally irritable, and disagreeable to himself and to others.

After four years of medical treatment, it did not seem wise to try that any further. I advised that the cicatricial tissue should be cut out and that trephining or further exploration should depend upon the indications—an opinion in which Dr. Weir Mitchell concurred after seeing the patient in consultation.

The operation was performed by Dr. Warren, October 29th, in the presence of Dr. Weir Mitchell, Dr. C. B. Porter and myself, but nothing was found to justify any apprehension of possible serious injury to the brain. There were three small indentations in the external table of the skull and trephining showed some reddening of the dura with adhesions to the adjacent bone. Dr. W. F. Whitney found, on microscopical examination, diffuse hyperostosis of the skull, and interstitial neuritis in the cicatrized tissue.

The patient made a complete recovery, has been able to resume his studies, and has remained entirely well.

CASE II. Miss —, aged twenty years, was seen by me in January, 1891, complaining of persistent dull headache, obstinate constipation which did not yield to ordinary remedies, and of paroxysms of severe pain throughout the head, with mental confusion beginning a few days before menstruation and lasting a week or more.

The patient's health had otherwise been excellent except for debility and some neurasthenic symptoms of three years' duration, which began a few months before the appearance of her headaches, and which had been attributed in part to worry and in part to a life involving some exposure on a cattle ranch in the West, with food not altogether suited to her somewhat exacting needs. She had lost twenty pounds in weight.

The family history was negative.

In July, 1884, the patient was kicked in the head over the upper and posterior portion of the right temporal bone by a well-shod horse. There was a large irregular scalp wound which got filled with sand and gravel. The wound was tied up and healed by granulation. There had been no unconsciousness or cerebral symptoms of any kind. There was no headache of consequence until nearly four years later, in 1888,

¹ Read at the meeting of the Association of American Physicians, Washington, D. C., May 29, 1894.

⁷⁰ Boston Daily Advertiser, April 18, 1894.

⁷¹ New England Medical Gazette, 18-0, xv, 65.

when she was again thrown from a horse and dragged about fifty feet, being debilitated at the time. She was also generally bruised about the same time in a third accident with a horse. Then severe and persistent headaches began, gradually becoming worse, and being at last completely disabling a few days before menstruation.

The more or less constant headache was quite moderate in degree and attended with slight mental confusion, which became quite marked at the time of the severe headaches of the menstrual period. There was also a degree of a peculiar motor aphasia at such times with hysterical symptoms, and there were often acts of cerebral automatism and attacks resembling petit mal.

After fourteen months of treatment the general health was restored, the constipation was relieved, and the persistent headache was somewhat better, but the paroxysmal attacks which have been described were not very much improved. There was nothing peculiar in the character of the headaches, which were general all over the head; and there was no tenderness in or near the cicatrix, which was irregular and ragged in shape, an inch and three-quarters long, and at the widest part nearly a quarter of an inch broad. It may be said in passing, that in this case and in the preceding case, the diagnosis had been made of *contrecoup* injury to the brain.

The cicatrix was removed by Dr. Warren in March, 1892, with complete relief to all the symptoms which I have enumerated.

Dr. W. F. Whitney found in the cicatricial tissue marked interstitial neuritis.

CASE III. F. R., aged eleven years, seen November, 1892, in consultation with Dr. V. Y. Bowditch; of neurotic temperament and family history.

In 1886 he was stunned by a fall, striking on a curbstone, with the result of a small scalp wound over the right frontal region about an inch above the supra-orbital ridge. In 1888 he was thrown from a small cart over a stone fence and was unconscious for a considerable time. There was a small scalp wound over the superior and posterior portion of the right temporal bone from this accident. In the same year he was partially stunned by being thrown from the rear platform of a street-car. His only serious illness had been intermittent fever in Italy.

Between two and three years after the second injury to the head he began to have persistent headache of slight degree, with frequent paroxysms of intense pain throughout the head. He lost flesh, became very thin and irritable, and had to give up study and reading. He also had frequent attacks of partial loss of consciousness, the precise nature of which I never ascertained. The only one which I saw resembled petit mal and probably was that. The eyes had been examined by an expert and found without defect. Medical treatment had been exhausted.

The two small, faint cicatrices were excised by Dr. Warren, November 23, 1892. The relief from the operation was not immediate, but gradual, and in a month's time the patient was virtually well in every respect. Two months later he was run over by a sled, the runner striking the upper cicatrix, and he was at about the same time accidentally struck a heavy blow over the other scar. There were pain and tenderness over both for three days, and the headaches returned, to be soon relieved by massage, and the patient returned to his school. A short time afterward

a new type of headaches appeared which were distinctly periodic and in part yielded to quinine, but which did not absolutely disappear until a re-examination of the eyes and the use of glasses for a trifling astigmatism.

Interstitial neuritis was found in the tissue of one scar by Dr. W. F. Whitney. There was considerable cell infiltration around the perineurium, as in the other cases.

These three cases were reported chiefly from the pathological point of view, and with illustrations of sections under the microscope, by Dr. Warren, at last year's meeting of the American Surgical Association.

CASE IV. Miss —, aged nineteen years, seen by me in February, 1891.

Family history good, except for recent alcoholism in one of the parents.

At the age of eleven years she struck her head violently against a spike, making a wound through the scalp which left an irregular, ragged cicatrix an inch long just to the right of the median line, and over the posterior portion of the parietal bone. Six years later the patient fell backward from a piazza eight feet high, striking the back of her head on a rock. She was unconscious for some time, and for several months there were pain and tenderness at the seat of the injury. There was no flesh wound.

Very troublesome headaches appeared a few years after the first injury, and were not increased after the second accident. They did not yield to treatment, and were so constant and severe that the patient had to give up school, and finally all mental work. The disability increased, and there had been for a year before I saw her a dull mental state, occasional mild melancholia, cataleptiform attacks and imperative conceptions, with a generally debilitated physical condition.

The patient was well developed; not well nourished; the internal organs and the eyes were free from disease or defect.

After trying medical treatment for four months without much benefit, except to make the physical state one of apparent health, I advised excision of the cicatricial tissue, which was done by Dr. Post, June, 1891. The result was entirely satisfactory in dispelling the headaches and all the morbid nervous and mental symptoms.

CASE V. W., aged thirteen years, was first seen by me in 1884. There was a neurotic tendency in the family, which his parents had tried to counteract by country life and sensible habits of living. The boy was physically strong, well formed, and with the external appearance of physical health.

Somewhere about 1880 to 1882 he had received three severe blows on the head, the precise dates of which could not be learned, in play with other boys. From two there was no indication as to the site of the injury. The third, from the corner edge of a hoe, left a ragged scar a little over an inch long over the upper and superior portion of the right parietal bone. I could not ascertain just when his headaches appeared, as the precise time had been forgotten, but it was some months after the injuries; and when I saw the patient they had become entirely disabling, so that the boy was obliged to give up the common occupations and amusements of his age. He was irritable to the last degree, with very little initiative or interest or power of self-control, timid and apprehensive. He

had frequent attacks of loss of consciousness, no one of which I ever saw, but which I supposed to be petit mal. A description of his various nervous and mental morbid symptoms, including a very curious type of topophobia, for the next six years, occupy many pages of my note-books.

Treatment for seven years under the most favorable conditions, the greater part of which was in the country under judicious direction, and away from home, was only disappointing in its results. Although there was some gain, the patient was a young man of twenty years, quite unable to take his part in the world in anything but the simplest vegetative life.

The cicatrized tissue was excised by Dr. Post, June, 1891. The headaches ceased at once, and all the other neurasthenic and mental symptoms almost as soon. The young man entered a large business house, in which he worked hard and has done well.

CASE VI. Miss —, seen in 1882, on account of frequent and severe epileptic convulsions. She was nineteen years of age, well developed, talented, accomplished, with a well-trained mind.

The family history was excellent.

Ten years before, when she was nine years old, she fell backward from a high swing and struck the back of her head violently on the ground. A few weeks later she began to have attacks of petit mal, which, as time went on, became more frequent, and in a few years there were also typical epileptic seizures, which occurred mostly at night or before breakfast in the morning. She had been under the care of the leading specialists in Boston and New York, and had been treated by Dr. Brown-Séquard. None of the treatment did any good, and some made her worse. After exhausting, as she supposed, the regular pharmacopœia, she was taking a proprietary medicine, which, on chemical examination, proved to be chiefly bromides; and while fully bromidized, she had more severe and more frequent attacks of epilepsy than ever before.

She had had for many years — none of the family could say how many — a persistent nagging headache, which had at last made her excessively irritable and difficult to get on with, although she was naturally most amiable.

Nothing abnormal was detected on physical examination. To bodily symmetry there was added a highly-trained, well-developed mind. No cicatrix was found, only a slight local tenderness on hard pressure.

The attacks of petit mal were often from twenty to thirty in twenty-four hours, and the grand mal once in a few weeks. After nine years of treatment the patient was, to all appearances, in a condition of blooming physical health. Very few people knew of her frequent attacks of petit mal, which were mostly in the morning, and of true epilepsy once in two to four months. The headache, chiefly in the back part of the head, persisted, and the patient had become more irritable and self-willed, more difficult to live with, in spite of greatly improved general health.

This patient, by the way, is the only one in my experience who has taken borax for a long period of years with greater benefit than from any other medicine.

The sensitive area, about as large as a silver half-dollar, remained just to the right of the median line and above the occipital protuberance where she struck when she fell, and where a marked unevenness could be felt on the outside of the skull.

It was thought that the conditions might be similar to what was found in the first case reported, and such proved to be the fact. The operation of trephining was done by Dr. Bradford, assisted by Dr. Monks and Dr. Brackett, in September, 1891. There was no distinct indication for opening the dura, and that was not done. The bone removed was quite irregular in thickness, but was, unfortunately, lost on the way to the pathologist.

As a result of the operation, the headaches quite disappeared, the attacks of both kinds have greatly diminished in frequency, and the irritability and impaired self-control are things of the past. The young lady's parents say that life with her is now a constant pleasure, and she herself takes her full part in social life, believing that, as she rather overstates the results, she has had a new life given her.

Observations might be made, and inferences could be drawn, and pathological theories and physiological speculations are possible on these cases, that would be interesting and perhaps instructive. But I have not had time to make them short, and you have not the time for me to make them long.

The symptoms described were evidently reflex and secondary for the most part. So far as they were direct, they were due to more or less extensive alterations in the nerve and to the existence of pressure.

TUMORS OF THE BREAST.

J. COLLINS WARREN, M.D.,
Professor of Surgery in Harvard University.

THE following cases are selected for the purpose of illustrating certain points in the diagnosis and treatment of tumors of the breast, and are presented as a contribution to the clinical study of disease of this organ which may prove of interest to the general practitioner.

They emphasize the importance of an early diagnosis and the necessity for the most radical type of surgical operation in cases of malignant disease. In spite of the greatly increased severity of the operation the percentage of mortality is constantly diminishing, owing to the improved technique, not exceeding at present 2%, and convalescence is rapid. There is little doubt also that the percentage of cases of permanent cure of cancer is steadily increasing under the present system of treatment.

MEDULLARY CANCER OF THE BREAST. — REMOVAL OF THE PECTORAL MUSCLES.

S. E., forty-five years old, having good general health, first noticed a lump in the right breast while bathing, on August 1, 1892. There was no pain or tenderness at that time. The breast was examined by Dr. Helen Morton on December 6, 1892, when a tumor of glandular outline was noticed in the right breast and below the nipple. There was no pain. The patient had, however, had some pain like that of writer's cramp in the right arm for two or three years. Menstruation had been more copious for the last two years, the intervals being shorter; the last one being only two weeks long.

The family history of the patient was good, there being but one suspicious case of malignant disease in the family, an aunt having died at about seventy years of

age with some abdominal disease thought to be cancer, though no autopsy was made.

I first saw the patient on December 27th, and on examination found a tumor in the outer hemisphere and considerable enlargement of the axillary glands.

The operation was performed on January 1, 1893. It consisted in amputation of the breast and a free dissection of the axilla, together with the removal of the greater portion of the pectoralis major muscle, and the whole of the pectoralis minor muscle. The wound was closed throughout by interrupted sutures, and healed by first intention except at one point, where a small abscess formed around a catgut ligature. The patient left St. Margaret's Hospital for her home two weeks after the operation, and the abscess healed soon after.

The following is the microscopical report of the specimen made by Dr. W. F. Whitney:

"The tumor of the breast of S. E. (St. Margaret's, January 1, 1892), was a soft medullary nodule, close to the nipple and lying deep in the breast tissue, its lower surface against the fascia, through which, however, it could not be seen to have broken.

"Microscopic examination showed it to be made up of large masses of very large epithelial cells, separated by a little fibrous tissue stroma. The axillary glands were large, but without any distinct nodules of new growth. The microscope showed, even in the smallest, a few scattered large epithelial cells mixed in with those of the glands proper.

"The diagnosis is medullary cancer, with secondary infection of the lymph-glands of the axilla."

The malignant character of the growth in this case, and the involvement of the glands of the axilla necessitating a careful dissection as high as the clavicle, rendered the prognosis extremely unfavorable, and a statement to that effect was made at the time. The patient, however, recovered her health and strength entirely after the operation, was able to visit the World's Fair and enjoy herself the following summer; and the report in answer to frequent inquiries from myself is that there has been no return of the disease up to the present time (May, 1894). The favorable result of the operation in this case would seem to be due in some measure to its radical nature. The necessity of such an operation was forced upon me at the time by the extensive infection of the breast, and the result has been a most encouraging one for cases of this class.

CANCER OF THE BREAST ORIGINATING FROM A CHRONIC MAMMARY TUMOR.

Mrs. F., fifty-one years old, was examined by me in June, 1893. Her father lived to be eighty-nine years of age, and died of cancer in the neighborhood of the eye. Her brother also suffered from a suspicious growth in the eyebrow, which was removed by me several years ago, and has never returned.

Before the patient's marriage, at the age of thirty, she had noticed a small lump in the lower, outer quadrant of the left breast, which had been regarded as a chronic mammary tumor. This had given her no trouble, although she had since passed through several confinements. No change was noticed in the tumor until about February, 1893, when it began to enlarge, and for two weeks before my examination it had involved the skin above it. At the time when I saw it there was a red lump involving the gland, slightly tender and communicating with a nodule in the right lower quadrant of the left breast. Glandular enlargement was felt in the axilla. The patient's general health had been good.

The operation was performed on June 12th, and a careful dissection of the axilla was made, with the removal of the breast, together with the fascia of the pectoralis major muscle. The muscles were, however, undisturbed. The wound was closed throughout by interrupted sutures, no drainage-tube being used, and it healed by first intention, the patient leaving St. Margaret's Hospital on June 30th.

"The specimen from the case of Mrs. F. showed a prominent nodule involving the skin, of a dark-reddish color, about the size of a small peach. Section through this gave a grayish opaque surface, gradually merging into a more whitish translucent one, in which were numerous irregularly shaped fissure-like openings. This latter portion was quite sharply defined from the rest of the breast tissue.

"Microscopic examination showed the soft growth beneath the skin to be composed of solid masses of epithelial cells separated by relatively narrow bands of fibrous tissue. The rest of the tumor into which this gradually passed was made up of a fibrous-tissue basis in which were portions of gland tissue, some markedly dilated in an irregular manner by in-growths of the connective tissue.

"The axillary glands were enlarged, and presented the same character as the soft growth first described.

"The case is one of a chronic intra-canalicular papillary fibroma, in one part of which a medullary cancer has developed." (W. F. Whitney.)

The patient made a good recovery from the effects of the operation, and was able to visit Chicago during the summer; but in the course of the autumn a cough developed, and the patient's strength slowly and gradually failed. Emaciation set in, and finally an examination about January, 1894, showed the presence of a small nodule in the outer portion of the cicatrix, and a marked dulness over the upper portion of the left lung. From this time on, the patient failed more rapidly, and died in March, 1894.

The origin of cancer from a benign tumor of this nature is undoubtedly rare. The fact, however, that malignant disease may develop from such a growth is a reason for operative interference, even in the mildest forms of this affection. In many cases of chronic mammary tumor appearing in young girls shortly after the period of puberty, I have advised non-interference, and have been able to follow the history of one or two such cases for a number of years, and have found that they have given no trouble whatever. After the experience in the above case, I should feel less disposed to give such advice in the future. Benign tumors of this nature may, however, take on a rapid growth early and assume a comparatively formidable size. Inasmuch as under these circumstances they may develop into a sarcoma attaining sometimes great size, and assuming a very malignant type, it is important that they should be removed without delay, as was done in the two following cases:

ADENO-FIBROMA OF THE BREAST.

Miss H., nineteen years of age, noticed a growth in the right breast in the upper and outer quadrant, in August, 1893. The tumor grew slowly at first, but, during the three months previous to my seeing it, had increased in size more rapidly. There is no history of any such tumors ever having been observed in any member of her family. The case was seen by me first in April, 1893. On examination, a nodular, well-defined growth, about the size of a small orange, was observed in the locality above mentioned. It was freely movable under the skin, but seemed firmly attached to the gland tissue. There was, however, a well-defined outline to the growth. There was no enlargement of the axillary gland.

The operation was performed during the same month, the tumor being dissected from its attachment to the mammary gland without difficulty; and the wound healed by first intention. An examination of the growth, by Dr. W. F. Whitney, showed the tumor to be an intra-canalicular papillary fibroma. Two or three small glands removed from the axilla were found to be simply hyperplastic. In response to a recent inquiry, the patient states that there has been no return of the growth.

The second case of this affection is the following:

Miss J., twenty-two years of age, consulted me in June, 1893, for a tumor of three years' duration in the right breast, in the upper and outer quadrant. The patient was a tall and slender person, but in good general health. There was no family history of any such growth. The case was in all respects similar to the one just reported, and microscopical examination showed the growth to be of the same nature. The wound healed by first intention, and the patient made a rapid recovery from the operation. In the early fall she was married. During the course of the winter she suffered from an attack of the "grip," which was followed by symptoms of pulmonary consumption, from which she died about the first of April, 1894. There had been no return of the tumor, and her breast had given her no trouble or inconvenience of any kind since the operation.

MEDULLARY CANCER OF THE BREAST. — OPERATION, INCLUDING REMOVAL OF THE PECTORAL MUSCLES.

M. F. M., fifty-two years of age, consulted me in March, 1894, for a growth in the upper hemisphere of the breast, which she thought had been growing for about three months. On close questioning, however, the patient remembered that she had occasionally felt a lump during the past year or so, which had subsequently disappeared. There was no history of any cancer in the family. Her general health was good, but she had not been strong, and had suffered from neuralgia in the arm, for which she had been under the treatment of Dr. J. J. Putnam for some time. The breast had given her some discomfort on arranging her dress, early in the autumn, and the presence of a lump was first definitely noticed early in December.

The operation was performed on February 3, 1894. The infiltration of the breast and axillary gland was found to be so extensive that it was thought desirable to remove the greater portion of the pectorales, major and minor. After the removal of these muscles, a nest of these glands forming a nodule the size of a pea was found just beneath the edge of the clavicle and beyond the apex of the axilla. The following is the report of Dr. W. F. Whitney:

"The specimen from the case of Mrs. M., received on March 3d, consisted of the breast and contents of the axilla.

"On the breast was a nodule the size of an English walnut situated just outside of the nipple, which was not retracted. The section surface of the growth was in general of a uniform grayish, slightly opaque aspect, with numerous yellow opaque dots and lines; the periphery passed into the adjacent fatty and fibrous tissue by an irregularly, slightly-retracting outline.

"Microscopic examination showed the growth to be made of solid masses of relatively large, irregularly-shaped cells, many of them extremely fatty degenerated. Between the masses was a fine vascularized stroma of connective tissue rich in round cells.

"The lymphatic glands from the axilla were enlarged from the size of a pea to that of a cherry, and were infiltrated with a new growth similar in gross appearance and microscopical structure to that of the breast.

"There was a wide margin of sound tissue about the tumor, and no evidence of disease was found in the muscle removed.

"The diagnosis is medullary cancer, with secondary growth in the lymph glands."

The nature of the growth and its extension close to the boundary line of the axillary space make the prognosis of this case (in spite of the radical nature of the operation) an unfavorable one. If there be a long period of immunity or a cure in this case, the fact that glands of considerable size were traced to the edge of the clavicle, would become a point of interest to the surgeon, as indicating that although the disease had made considerable progress up to this point, it need not necessarily have involved the lymphatic region beyond.

In making a diagnosis in the case of a growth in the breast, it is important to remember the earliest symptoms which enabled us to determine the presence of cancer. One of the most important of these — and perhaps the most frequent period in this part of the world — is the age which has been mentioned in the cases above quoted. The most frequent period commonly ascribed to cancer, is between forty and fifty years, but in my experience the most prolific years are from fifty to fifty-five. One point of value is the seat of the disease, which in cancer is more frequent in the upper hemisphere and in the outer hemisphere, the upper and outer quadrant being, therefore, the most frequent of all localities. The retraction of the nipple does not appear to be of much value as a symptom in the early stages of the disease, a time when an accurate diagnosis is of the greatest importance.

(To be continued.)

Clinical Department.

SURGICAL CASES.

REPORTED BY C. L. SCUDDER, M.D.

THE following operations were done by the Surgeons of the Staff on duty at the Massachusetts General Hospital on Tuesday, June 12, 1894, before the members of the Massachusetts Medical Society at the Annual Meeting. The operations were performed in Ward E, the abdominal and cerebral ward of the hospital, and in the public operating theatre.

CASE I. A man with fecal fistula. Operation by Dr. M. H. Richardson for closure of the fistula; end-to-end suture of the bowel; gauze drainage. Recovery.

The patient was a man thirty-one years old. Two years ago history of obscure abdominal trouble, which in October, 1893, was relieved by operation, with the immediate establishment of a fecal fistula. The fistula has been open to both feces and gas, although the rectum has been functionally active. The sinus leading to the bowel was dissected out; all cicatricial tissue removed from about the bowel; the intestine divided, and the ends united by an interrupted Lambert suture. Throughout the operation there was very great hemorrhage from the vessels in the cicatricial tissue about the fistula and the very large mesenteric veins. After suturing, a bit of gauze drainage was left projecting from the abdominal wound reaching to the wound in the intestine.

CASE II. Male. Recurrent sarcoma of the thigh. Amputation in the upper third of the thigh. Recovery.

The patient, aged thirty-two, entered the hospital in April, with a history of an injury ten weeks previously

to the left knee-joint. The region of the knee was greatly swollen and extremely sensitive.

An amputation was done by Dr. M. H. Richardson in the lower third of the thigh April 21, 1894.

Examination of the specimen demonstrated that it was a spindle-celled sarcoma. To-day the patient having recovered from the previous operation, and there being some recurrence in the stump, a reamputation was done in the upper third of the thigh. The bone was found healthy, but there was a general oozing from the stump, so that the permanent dressing was not applied until later in the day, primary dressing being a packing with gauze.

CASE III. Woman. Perinephritic abscess. Drainage. Recovery.

The patient, a woman thirty-one years old in July, 1893, had the following symptoms: frequent micturition and foul urine. Five months ago a swelling appeared in the right iliac fossa, accompanied with great loss of flesh and strength.

Examination finds in the lower half of the abdomen, on the right side, extending well into the right loin, a tumor. Fluctuation is obtainable from the right iliac region backward into the loin through the tumor.

Operation by Dr. M. H. Richardson. Incision from the tip of the last rib to the crest of the ilium obliquely towards the iliac crest. An abscess cavity was opened, from which a large amount of foul, thick, greenish pus was removed. A counter-opening was made in the right groin, and the cavity was well douched and drained by tube and gauze.

CASE IV. Woman. Epithelial growth of the leg. Amputation at junction of the middle and lower third of the thigh. Recovery.

The patient, a woman fifty years old, had had all her life ulcers of the leg, which had at times entirely healed. At present there is an ulcer in the middle third of the leg, with raised edges, and a base extending deeply to the bone. Microscopical examination by Dr. Whitney proved the ulcers to be malignant.

Operation by Dr. M. H. Richardson. Amputation of the thigh by antero-posterior flaps, about three and a half inches above the joint.

CASE V. Double ovariectomy.

The patient, thirty-five years old, and married, has one child five years old. Has been married twelve years, and during the past ten years has had some pain in the left side, together with a constant dragging feeling in the pelvis; leucorrhœa for years; has had recently chills and fever.

Examination finds a woman well-nourished. Vaginal examination finds the cervix and uterus in the middle line. The uterus is slightly retroverted; the left ovary is enlarged; both ovaries are prolapsed and held fixed by adhesions. The uterus is normal in size.

Operation in Trendelenberg position by Dr. F. B. Harrington. Incision in the linea alba. Uterus found retroverted; both ovaries prolapsed. Both ovaries removed; broad ligaments tied off with silk. Uterus was freed from adhesions, and brought up into the abdominal wound, and two silk sutures passed from the fundus of the uterus through the peritoneum and fascia of the interior abdominal wall. Abdominal wound closed.

CASE VI. Boy. Stone in the bladder. Litholapaxy. Recovery.

The patient, aged three years, was well until eight months ago, when he began to complain of pain in

both groins. Pain is intermittent—worse with micturition and upon running about—sharp in character. The child was treated by Christian scientists for four months without improvement! Pain is increasing in severity and frequency; micturition is frequent; and urine is now passed involuntarily. The child has a long prepuce.

Operation by Dr. F. B. Harrington. A stone was detected by sounding the bladder, and it was crushed by a small-sized lithotrite.

CASE VII. Old pelvic abscess. Abdominal section, with removal of the abscess wall by dissection through an abdominal incision.

Patient, a woman thirty-eight years old, came to the hospital with a pelvic abscess May 17, 1894. This abscess was opened anteriorly through the abdominal wall and through the vagina. Drainage by tube through the vaginal opening; this drainage appeared to be insufficient. It was thought wise to reopen the abdominal wound, and to dissect out, if possible, the sac of the abscess. The incision opened the abscess cavity, which was washed out clean, and the edges sutured together, thus preventing the abdominal cavity's infection by the foul abscess; and the section was carried around on either side of the abscess wall until a greater part of the wall was removed. Both Fallopian tubes were found enlarged and full of pus. Both tubes were freed from adhesions and removed. The cavity remaining was drained by iodoform gauze and a glass tube. Patient was in poor condition at end of operation, but has recovered well with no rise of temperature.

Dr. C. B. Porter showed a case of extreme interest and importance:

A fracture of the surgical neck of the humerus, complicated by dislocation of the head beneath the coracoid process of the scapula. The operation for reduction of the dislocated head of the humerus was done fifteen days after the accident.

The shoulder-joint was approached through a U-shaped incision through the deltoid muscle. The head of the bone was found out of the glenoid cavity. A drill-hole in the anterior surface of the head of the humerus was made allowing a blunt steel hook to be inserted into the bone. Traction was made by the hook outward, aided by pressure of the thumb, this reduced the head of the humerus into the glenoid cavity. The wound was closed in the soft parts, a sterile dressing applied, and the arm held fixed by a plaster-of-Paris dressing around the chest and shoulder. In five weeks the apparatus was removed in the day-time, and worn a short time longer at night only. Union was firm in five weeks.

Eight months after the operation: The motion in the dislocated shoulder is about perfect; the arm, the patient reports, is as useful as it was before the operation.

Dr. J. W. Eliot operated upon an acute appendicitis of four days' duration.

The patient had worked the day before the operation, but had much abdominal pain. The temperature was 99°, the pulse was 170. The abdominal wall was rigid, and there was pain in the right iliac fossa upon pressure. By an oblique inguinal incision the gangrenous appendix was found and removed. Pus was found free in the abdominal cavity. A counter-opening was made in the median line. Drainage with tube and gauze was made through both incisions.

Reports of Societies.

ASSOCIATION OF AMERICAN PHYSICIANS.

NINTH ANNUAL MEETING, WASHINGTON, D. C., MAY 29, 30, 31 AND JUNE 1, 1894.

(Continued from No. 25, p. 622.)

SECOND DAY. — WEDNESDAY.

DR. THEOBALD SMITH, of Washington, read a paper entitled

MODIFICATION, TEMPORARY AND PERMANENT, OF THE PHYSIOLOGICAL CHARACTER OF BACTERIA IN MIXED CULTURES.

An accidental contamination of a culture of the hog cholera bacillus with *Proteus vulgaris*, both probably inoculated together from the original material, gave rise to a remarkably rapid attenuation of the pathogenic bacteria. The symbiotic growth had lasted about three months before it was discovered. The attenuation showed itself when rabbits were inoculated into the abdomen. A prolonged disease associated with the eruption of pseudo-tubercles took the place of the usual inoculation disease. Subsequent trials with mixed cultures of *P. vulgaris* and hog cholera bacilli yielded the same result. The cultures of the former after repurification failed to destroy rabbits after subcutaneous inoculation.

An unexpected outcome of these observations was the return to a higher level of virulence of the hog cholera bacilli in pure agar cultures in every case. This return did not come at once after *Proteus* had been removed, but appeared in two cases nine months after the culture had been purified and grown on agar continuously.

Another result of these mixed culture experiments was the appearance of a series of varieties of the *Proteus* culture, all descended from one colony originally. Two of these corresponded closely with Hauser's *P. mirabilis* and *P. zeukeri*.

These marked changes in mixed cultures are suggestive when taken into consideration with the life processes of bacteria in the depths of the soil, especially in polluted soil in which the bacterial flora may be presumed to be most abundant and active. The possibility of an ectogenic development of the non-toxic species which act as true disease germs is made plausible and deserves further attention.

The method of mixed cultures may prove useful in obtaining different degrees of virulence of the same organism, so essential in the study of the relation between the host and the parasite, or, in other words, immunity.

DR. G. M. STERNBERG said that a few years ago bacteriologists were disposed to look upon cultures which showed small differences as being of different species. We now know that the colon bacillus, the typhoid bacillus and other organisms undergo various modifications. Liquefying organisms may fail to liquefy; phosphorescent bacteria may after a time fail to produce phosphorescence, and the pigment bacteria may fail to produce their pigment. Starting with pure cultures from the same source, we can get a large number of varieties. It is still to be decided whether any of these varieties do have permanent characters and fail to return to the original type.

Referring to the researches of Dr. Martin, reported

by Dr. Ernst, Dr. Sternberg spoke of the pathogenic power of a pseudo-tetanus bacillus which had been cultivated in the soil where the tetanus bacillus had previously been cultivated, and after being propagated through successive tubes, still killed animals with all the symptoms of tetanus. This fact corresponds with the results obtained by Dr. Martin in his inoculations with a particular bacillus obtained from the vaccine lymph. After several generations he still produced a typical vaccine vesicle. Whether his bacillus would continue to do so indefinitely is a matter to be determined by further experiment.

DR. WM. H. WELCH said it was well to bear in mind that nearly all of the artificial modifications produced by the action of different agencies on bacterial cultures are changes in function, and not morphological changes, and that the present tendency among biologists is to eliminate, so far as possible, in the classification of species, physiological properties. In these observations there is nothing that necessitates our supposing that these changes justify the recognition of anything more than races and varieties, and not of separate species.

Dr. Welch agreed with Dr. Smith as to the remarkable tenacity of the hog-cholera bacillus in its pathogenic properties. This is contrary to the statements of Selauder, and of Metchnikoff and others who have worked with the hog-cholera bacillus. Selauder claimed to increase the virulence of the hog-cholera bacillus so that it became a germ almost identical with that of ordinary rabbit septicæmia that would kill in twelve to eighteen hours. His work has been gone over repeatedly here, but without the same results. It is quite evident that these foreign observers are working with some different organism.

As to the lesions in the intestines of rabbits which Dr. Smith attributed to the attenuated bacillus, these same lesions have been found occasionally after inoculations with the ordinary hog-cholera bacillus.

The results obtained by Dr. Smith are very suggestive that the conclusions which we draw from experimenting with pure cultures are not exactly applicable to the real conditions as they exist in nature, where the different micro-organisms are associated in various ways.

DR. THEOBALD SMITH said that he had studied the typhoid-like lesions produced by hog-cholera, and had come to the conclusion that they can only be produced in two ways: either by an attenuation of the germ, or by an increase of the resistance of the animal.

DR. MEADE BOLTON, of Baltimore, then read a paper entitled

THE EFFECT OF VARIOUS METALS ON THE GROWTH OF PATHOGENIC BACTERIA.

Some metals seem to leave no influence upon the growth of the bacteria, while others have a more or less marked inhibitory action, as shown by a broader or narrower clear zone around the pieces of metal on plates otherwise crowded with colonies of bacteria.

Just outside the clear zone, whether this is broad or narrow, there is nearly, in every case, a zone of intensified growth where the colonies are thicker than on other parts of the plate.

In the few tests as yet made for this purpose, there was entire absence of living bacteria in the clear zones. Inoculations from the clear zones remained sterile.

In some cases there are three zones around the

metals, namely: a clear zone immediately surrounding the metal, a zone of intensified growth, and a second narrower zone where growth was inhibited.

It has been possible to detect in the medium, by chemical reagents, the presence of traces of those metals that exert inhibitory power.

The solution of the metals in the nutrient medium takes place independently of the growth of bacteria, as it is possible to detect the presence of the metals in sterile media in which they have been placed, after they have lain for a few days, at any rate. A discoloration of the medium surrounding the metal often makes a special test unnecessary.

Some metals have a much more powerful inhibitory action than others, as is shown by the broader clear zone. There is also some difference in the different bacteria with one and the same metal.

Some of the metals that have been tested were absolutely pure; others were commercial metals, marked chemically pure, and a few were either impure or alloys.

DR. W. H. WELCH said he was very familiar with the investigations of Dr. Bolton. The most mysterious thing about them is the clear zone outside of the intensified zone. The first clear zone immediately around the metal is unmistakably due to a solution of the metal in the form of oxide or salt. The most probable explanation of the intensified zone is that there is a minimum amount of metal there which is favorable to the growth of the bacteria, whereas the larger amount in the clear zone is a poison to the bacteria, and prevents their growth.

DR. W. GILMAN THOMPSON, of New York, read a paper entitled

NOTES ON THE OBSERVATION OF MALARIAL ORGANISMS IN CONNECTION WITH ENTERIC FEVER.

The possibility of typhoid and malarial fever manifesting their symptoms at one time in the same individual has afforded a fertile subject for debate for many years, with the result that the belief in the simultaneous action of the two infections has been generally losing advocates. The theory originally advanced by Woodward, that a "typho-malarial" fever exists as a specific and independent disease, has been abandoned by competent clinicians and by Woodward himself, although it is occasionally revived in the South and Southwest, in discussions upon the continued fevers of the South. The belief is almost universal that typhoid fever, as observed in New York, is uncomplicated by malarial infection, and that quinine, except as a tonic in convalescence, is worse than useless in its treatment. For this reason, the cases of the author seen in New York last summer and autumn are of unusual interest.

CASE I. The patient, J. McN., male, forty-three years of age, was admitted to the Presbyterian Hospital, August 18, 1893. He had continued fever which lasted for seven weeks, during which time he developed the following symptoms: A genuine typhoid eruption, there being some forty distinct rose spots on the abdomen and chest, which appeared in successive crops; hæmorrhages from the bowels, tympanites, bronchial catarrh, slight albuminuria with granular casts, semi-stupor and delirium, subsultus, great prostration and emaciation, and the facies of the typhoid condition. On the thirteenth day of the illness there was a severe chill, lasting about three-quarters of an

hour, and so violent that the patient shook the bed. It was accompanied by a rise of temperature to 106.6° F., but there was no sweating. During the third week two other chills occurred of equal violence. The malarial plasmodium was found in exceptionally large numbers invading the red blood-corpuscles and also independent of them. The hypodermatic administration of quinine reduced the temperature very markedly. No more chills occurred after the beginning of the fourth week, but the use of quinine was continued by the mouth, and the bathing, previously interrupted by the hæmorrhages, was resumed. The patient made a good recovery, and after fifty-five days in the hospital was discharged cured.

CASE II. The patient, J. J., an Irish laborer, thirty years old, had a typical case of typhoid fever, and was treated by the cold tub-bathing without medicine, receiving in all thirty baths. The temperature became normal on the thirty-first day, and remained below 99.4° F. for several days, and on the thirty-seventh day suddenly rose to 106° F., and was accompanied by profuse perspiration. There were chills and high fever on the two successive days at the same hour, and malarial organisms in abundance were found in the blood. From the continued giving of quinine the patient had no more chills or fever and in a few days was discharged cured.

CASE III. This case was very similar to the preceding one. The patient, after making a good recovery from typhoid fever, was about to be discharged as cured on the forty-first day, when he had a severe chill followed by fever and sweating. The chill was repeated the next afternoon at about the same time, also with increased temperature. Quinine was promptly given and the blood was not examined until the patient had received twenty grains. No malarial organisms were found, but abundant malarial pigment granules were contained in the blood-cells. Under the continued use of quinine, the patient recovered three days later.

While it is unwise to accept the term "typho-malarial" fever as indicating a third form of disease, which is neither typhoid fever nor malarial fever, it cannot be denied that the two latter diseases may co-exist.

DR. WM. M. OSLER, of Baltimore, thought the first case of Dr. Thompson's one of unusual interest, and he knew of no instances in the literature in which the two diseases had been so accurately and carefully described running concurrently. It would, however, be a great mistake to suppose that chills in typhoid fever always indicate malaria, since it is well recognized that they are by no means uncommon, and due to various causes. In the past year at the Johns Hopkins Hospital there have been several instances of typhoid fever with heavy chills in which the malarial parasites were not present. Dr. Osler exhibited a chart of the only case in which a patient was admitted to the hospital with a double infection of malaria and typhoid fever. He entered the hospital October 16th with tertian intermittent fever, the organisms being found in his blood. He was given quinine, and the temperature from the 18th to the 22d remained normal or subnormal. On the night of the 22d the temperature began to rise and did not fall to normal till the sixth week, during which time the patient had a very severe attack of typhoid with not a single feature pointing to any malarial influence. Dr. Osler also related an interesting case in which malaria and pneumonia were concurrent. Qui-

nine caused the parasites to disappear from the blood, but had no influence upon the temperature. These are the only two instances in a series of nearly 300 cases of malaria and 309 cases of typhoid, and with blood examined in all, in which malaria has occurred with another infection.

DR. F. P. KINNICUT, of New York, said that Dr. Thompson's first case was certainly a distinct double infection. We should, however, be guarded in our conclusions in regard to the frequency of these double infections until we have further observations. It is very possible to mistake a remittent fever for a typhoid, and as an illustration of this Dr. Kinnicut detailed the case of a patient in St. Luke's Hospital where this error had occurred. The practical lesson to be deduced from these cases is that the blood should be examined in every case of fever coming into the hospital wards.

DR. G. L. PEABODY, of New York, called attention to the fact that there are other chills occurring in typhoid fever which are of more importance than malarial chills. He had twice seen severe chills late in typhoid fever which were pyæmic in character, as proved by autopsy. He had seen severe chills followed by rise of temperature in typhoid, which did not affect the subsequent course of the disease, the patients getting well without quinine. It is important that the idea should not be given that typhoid and malaria is a frequent combination. That is a fallacy that prevails largely in the country districts of New York, and in some places every case of typhoid fever is treated as "typho-malarial" fever.

DR. E. G. JANEWAY, of New York, said that when a chill comes on in the course of typhoid fever, it is often not necessary to suppose that it is due to the intercurrent of other diseases, for it is due in many cases to treatment by the modern antipyretics. Drop the antipyretics, and the chills disappear.

That the two diseases are at times combined, is proven by the occurrence of both typhoid lesions and pigmentation at autopsy. Dr. Janeway reported a case showing these characteristics. Although malaria and typhoid sometimes coexist, it is not advisable to give the name "typho-malarial" fever to this combination; it should be called typhoid fever with malarial coexistence. Physicians who give the name "typho-malarial" to it, assure the family that it is not typhoid fever, and thus take away the preventive measures for typhoid fever, and the disease has spread in consequence.

DR. G. M. STERNBERG said that Dr. Thompson's first case was a clear case of mixed infection, which, in so pronounced a form, is rather a rare thing. The other cases showed the development of malarial fever during convalescence from typhoid, which is not a very rare occurrence in malarial countries. The cases presented by Dr. Thompson differ from those commonly diagnosed as "typho-malarial" in the Southern States and in other sections of the country. These cases are usually of the comparatively mild character, and do not present distinct malarial paroxysms. The temperature is often quite irregular during the first week, and remittent in character. This leads the doctor to make a diagnosis of malarial fever and to prescribe quinine. In the course of the second week the difference between the morning and evening temperature is not so marked, and he says that the fever has assumed a typhoid type. It has really been typhoid from the

outset. The war statistics show that the mortality from the fever diagnosed as typhoid, was very much in excess of that from the form denominated "typho-malarial" fever. If the typho-malarial was a mixed infection, it presents the anomaly of being less fatal than typhoid fever, in other words, the complication modified the severity of the specific fever. It is possible that there is a widely prevalent endemic fever which is specifically distinct from typhoid. If so, it is equally distinct from the malarial fevers, as quinine has no effect in terminating its course. In any case, the name "typho-malarial" is a mistaken one, and can only lead to confusion of ideas.

DR. J. C. WILSON, of Philadelphia, objected to the use of the term "typho-malarial." This term, so catching, and apparently so proper at the time it was coined, has done much harm and has stood in the way of advancement in the knowledge of fevers. Dr. Thompson's opportune presentation of these cases reopens the whole subject in a most fortunate way. His paper shows how much clearer and how much more definite the work of the medical profession is becoming with our newer and more exact methods of investigation.

DR. J. H. MUSSER, of Philadelphia, reported a case of mixed infection or rather of repeated infection. The child, nine years of age, had in the spring of 1893 an attack of intermittent malarial fever, and in the same year had a second attack which yielded to antiperiodic treatment. In December, the child had scarlatina. Four days after the temperature became normal, measles developed in the child. This was followed by otitis. During the course of the otitis, intermittent fever developed which promptly responded to the administration of quinine.

DR. H. M. LYMAN said that he had seen cases in which typhoid fever ran its normal course, terminating apparently, in convalescence; and then there were successive chills, with rise of temperature following. These chills were usually quotidian, but not at any certain hour of the day and not yielding to quinine, being also accompanied by slight jaundice. These cases have been explained by the French observers as due to the migration of the typhoid bacilli and other pathogenic germs from the intestines into the biliary passages, producing angio-cholitis, which is accompanied by chills and a certain amount of jaundice, not yielding to quinine but being far more benefited by local measures addressed to the liver. These cases must be carefully differentiated from the pyæmic cases, some of which are notable and easily recognized before their conclusion.

DR. W. T. COUNCILMAN said that there did not seem to be any special opposition to the growth of other organisms in the body due to the presence of the bacillus of typhoid. He reported in this connection a case interesting from the number of mixed infections. It was a case of typhoid fever which, while in the hospital, was accidentally exposed to diphtheria. The patient died in the third week of typhoid fever. Throat lesions were seen during life. There were marked typhoid lesions in the intestines; there was a typical diphtheritic process in the throat with false membrane. There was an acute endocarditis and a septic embolus in the spleen. There were typhoid bacilli in the spleen and mesentery glands; diphtheria bacilli in pure cultures, in the pharynx and lungs; streptococci in the bronchial and tracheal glands and

on the heart valves and in the septic embolus in the spleen. There was also a colon infection in the mesenteric glands, in the liver, and in the lungs along with the diphtheria bacillus.

DR. F. C. SHATTUCK, of Boston, said that some of the inexplicable chills which occurred during convalescence from typhoid fever might be due to phlebitis in the internal and inaccessible veins. The chills and subsequent pyrexia may be very similar to those accompanying phlebitis in superficial veins. The importance of a routine blood-examination is apparent. Phlebitis would be accompanied by leucocytosis.

DR. J. E. REEVES, of Chattanooga, Tenn., said that this fever, which has been described as a mixed fever, is a source of constant confusion to the physicians of the South. The clinical history of the fever called "typho-malarial," is not that of pure typhoid fever, and he thought it possible that there may be a species of fever intermediate between malarial and typhoid fever. In the so-called typho-malarial fever there is no diarrhoea, no epistaxis; there is a fitful rise and fall of temperature, and the course of the disease throughout is different from that of typhoid. The first attack makes the subject more permissible to a second and repeated attacks of the same disease. In typhoid, after recovery, the patient fattens up; in typho-malarial fever, the patient is debilitated, has a sallow appearance and probably does not recover his health for six months.

DR. GEORGE DOCK, of Ann Arbor, thought that the cases reported went but a short way in showing the existence of double infection in any proper sense. In Dr. Thompson's first case, the temperature chart did not show that there was any malarial element in the symptomatology before the chills occurred. In Dr. Osler's case the malarial infection seemed to have no influence at all on the course of typhoid. Dr. Kibyonn, of the Marine-Hospital Service, in 1890, reported patients who had typhoid fever and in whom he also found the malarial organisms. The so-called typho-malarial disease is often asserted to be milder than typhoid alone. From the cases reported to-day this is not shown to be the case. While in Texas, Dr. Dock had made autopsies in six cases, diagnosed as typho-malarial by experienced men, and in all cases the lesions were those of typhoid. He therefore concluded that fatal cases having a supposed malarial aspect, were not uncommon.

Such observations as those of Dr. Thompson ought to be repeated on every case of typhoid, especially in those parts of the country where the term "typho-malarial" is used.

DR. W. G. THOMPSON, said that the object of his paper was to make a contribution to the natural history of the malarial organism, rather than to discuss the wide subject of chills in enteric fever. The cases reported by Dr. Osler, taken in connection with his own, proved that the malarial organism may be present throughout the period of infection of typhoid fever. Just how far the malarial germ influences the action of the typhoid germ is a question which still remains undecided.

Two practical points may be deduced from this discussion. The first is the value of routine examination of the blood for malarial organisms in cases of enteric fever that are at all irregular; the second is, that we should determine the value of quinine in those cases where malarial organisms are present.

DR. THOMAS M. ROTCH, of Boston, read a paper entitled

SOME OF THE CHEMICAL AND BACTERIOLOGICAL CHARACTERISTICS OF MILK.¹

This paper gives the results of some investigations in cow's milk, as to its behavior with different breeds, and something about its bacteria; also some remarks on the ash of human milk.

DR. F. FORCHHEIMER, of Cincinnati, said that the work of Dr. Rotch is laudable, if only in the direction of telling us what is normal milk. The normal reaction of milk is undoubtedly alkaline. He had long ago given up the idea of correcting the reaction by adding alkalies, because that is only adding another element to already bad milk. A great number of troubles in infants arises from impure milk, and just as the surgeon protects his patients from sepsis, so it is the duty of the physician to protect infants from milk sepsis. Any one who has taken the trouble to centrifugate milk and examine impurities, will come to the conclusion that the best samples of milk in cities are extremely impure and very dangerous. Any one who has ever seen a centrifugate of ten to fifteen gallons of milk, knows that it almost acts as an inhibition upon the desire to drink milk in the future.

DR. THEOBALD SMITH said that the milk might be directly infected from the udder with disease germs other than tuberculosis. In a sample of milk, milked into a sterile bottle with ordinarily clean hands, he had gotten pure cultures of the staphylococcus pyogenes aureus. Referring to the centrifugalizing of milk, he said that the deposits, so far as the morphological elements were concerned, were made up largely of polynuclear leucocytes. In one case where the leucocytes were exceptionally abundant, the milk was found to contain tubercle bacilli; possibly there may be a relation between leucocytosis in milk and tuberculosis.

DR. T. M. ROTCH said that a practical result of the bacteriological examinations was, that where you cannot provide otherwise for properly sterilized milk, you can get practically sterile milk if you take the last half of the milking.

(To be continued.)

AMERICAN CLIMATOLOGICAL ASSOCIATION.

ELEVENTH ANNUAL MEETING, WASHINGTON, D. C., MAY 29, 30, 31 AND JUNE 1, 1894.

(Concluded from No. 25, p. 629.)

THIRD DAY. — THURSDAY.

On Thursday, in the absence of the President, DR. ISAAC HULL PLATT presided.

DR. LEONARD WEBER, of New York, read a paper on

SOME PATHOLOGICAL CONDITIONS OF THE HEART AND THEIR RELATION TO DIABETIC COMA.

He said that among the sixty cases of diabetes mellitus which he had treated in the course of his practice, he had seen a number die in coma. It is true that the majority of these were the well-known forms of diabetic coma brought about by acid intoxication of the blood, as it is supposed, by acetone and, especially, diacetic acid, but in addition also through the poisonous effects of ptomaines produced by the

¹ To be published in full in the Journal.

putrefactive processes so frequently occurring in the alimentary canal of diabetic patients; but quite a number go into collapse through deficient cardiac action, by disease of the heart developing in the course of diabetes, as already pointed out by Frerichs. In these cases there are generally no turbulent symptoms, but syncope followed by cardiac death. They might properly be named collapse-coma, as distinguished from the more frequent forms by blood-poisoning. The causes of neuro-muscular disease of the heart in diabetes are manifold. We have, in the first place, the wear and tear of the heart by a chronic disease producing functional weakness and predisposing it to dilatation and atrophy; fatty overgrowth, and later fatty degeneration in the diabetes of fat persons; the poisonous effects of acetone and diacetic acid upon cardiac nerve and muscle, and in addition those of ptomaines resulting from intestinal putrefactive processes. And arterial sclerosis and chronic nephritis, which are quite often associated with diabetes, also have a baneful influence upon the heart.

In the management of diabetes he believes it to be good practice to allow the patient a certain daily amount of carbohydrates as soon as the disease has been gotten under control, and has found this amount to be about three ounces. An absolute meat-diet cannot be maintained very long on account of disturbing digestion and placing the patient in danger of coma.

Every case of diabetes is to be investigated and studied by itself, and the treatment and management adapted to individual requirements. In addition to carefully regulated diet and mode of life, Dr. Weber has prescribed salicylate and bicarbonate of soda (gr. xv each) before meals, or Carlsbad water instead. Where the alkaline treatment did no good, or did not agree with the patient, he has ordered opium in small doses with benefit. In every case he saw good service from the use of massage judiciously applied, and the frequent use of baths. It is by the latter two remedies that the heart is kept fairly strong and active in this disease, which is as yet not curable but manageable.

DR. ROBERT H. BABCOCK, of Chicago, gave

A REPORT OF CASES OF CHRONIC HEART DISEASE TREATED BY THE SCHOTT METHOD OF BATHS AND GYMNASTICS.

The aim of the report was to direct attention to the value of baths and light exercises in cardiac therapeutics, by which it is believed patients suffering with organic heart disease of chronic nature may be more promptly and lastingly improved than by drugs. A statement of the rationale and application of this system was given. As to the baths: "The improvement in the rate and quality of the pulse is an index of the degree of benefit derived by the patient. If not counteracted by exercise, this effect on the pulse will persist for an hour or two subsequently. Changes for the better in the size of the area of cardiac dulness and in the sounds may be noted likewise. This was demonstrated repeatedly last year both on myself by a competent Russian physician, and by myself on others. Careful percussion immediately before and after a bath of eighteen to twenty minutes' duration, showed a demonstrable retraction of the deep limits of cardiac dulness and the heart sounds were improved in strength, the second pulmonary being less accentuated, the second aortic stronger—in short, the abnormal

difference between the two sounds before, being appreciably less marked after, the bath. Murmurs that are almost inaudible before become intensified; and, conversely, some loud bruits are lessened in intensity. In short, so far as can be determined by physical examination, these baths appear to lessen the rapidity and increase the force of the heart's contractions, thereby occasioning a better filling of the great arterial system with corresponding depletion of the engorged veins."

The exercises supplement and reinforce the balneologic treatment.

In a detailed report of 19 cases, 13 showed more or less improvement.

Contra-indications: "There can be no doubt of the danger of this form of treatment in degenerative changes of the blood-vessels and myocardium, such as aneurism and advanced arterio-sclerosis, acute softening and great fatty degeneration of the heart."

A NEW AND DISTINGUISHING SIGN OF LATENT ANEURISM OF THE AORTA,

by DR. W. C. GLASGOW, St. Louis.

The sign to which Dr. Glasgow referred, is the presence of a systolic sound, or thud, in the brachial artery, synchronous with the systole of the heart. This sound is sometimes accompanied by an arterial murmur. When this sound can be heard, and aortic regurgitation can be excluded, Dr. Glasgow claimed that a positive diagnosis of aneurism can be made, even in the absence of all other signs or symptoms. Dr. Glasgow reported five cases of aneurism in which this arm-sign could be heard. He also exhibited a patient from one of the Washington hospitals who showed this sign.

OZONE IN PHTHISIS, WITH ESPECIAL REFERENCE TO THE PNEUMATIC CABINET,

was the subject of a paper by DR. CHARLES E. QUIMBY, of New York.

FOURTH DAY.—FRIDAY.

THE COMPARATIVE RARITY OF PHTHISIS IN THE HIGHLANDS OF PENNSYLVANIA AND THE ADJACENT COUNTIES OF NEW YORK,

by DR. GUY HINSDALE, of Philadelphia, was the first paper read on Friday (DR. R. G. CURTIN in the chair).

Attention was called in this paper to the low mortality from consumption in a district falling partly within New York and partly within Pennsylvania, embracing an area of 12,000 square miles. Throughout this region, there is, according to the best available information, a population of over 1,000 persons living to each annual death from phthisis. The maritime district of New York, including West Chester County and Long Island, has a population of only 400 for every annual death from phthisis, while the seven counties of the southern tier, namely, Chautauqua, Cattaraugus, Alleghany, Steuben, Chemung, Tioga and Broome, have an average of 1,091 persons living to each annual death from phthisis. The Highlands of Pennsylvania particularly referred to, embrace the counties of McKean, Potter, Forest, Clarion, Elk, Cameron, Union and Sullivan. This entire region has an elevation of from 1,200 to somewhat over 2,000 feet; it is characterized by extensive forests, a dryer air and lower temperature than prevails at the seaboard or lake shore; and by reason of its distance from the storm

tracks of the St. Lawrence Valley and the changing temperature of the seaboard, it is eminently suited for the consumptive. In Pennsylvania, Kane, in McKean County, is very favorably situated, and has acquired considerable reputation as a resort in phthisis and hay-fever. Pneumonia, pleurisy and diphtheria are rare in this locality. The country surrounding Kane is an elevated table-land of 2,000 feet elevation; the water-courses are quite small, and fogs which are common in the deep valleys are not observed in this high plateau or "Big Level," as it is called.

SOME METEOROLOGICAL DATA OF COLORADO.

DR. SAMUEL A. FISK, of Denver, reported as a member of a committee of the Association appointed to collect meteorological data of the resorts of this country. Dr. Fisk exhibited tables giving a comparative study of the elevation, relative and absolute humidity, precipitation, velocity of wind, etc., of eighteen different stations scattered all over the United States. These tables were used mainly to illustrate the Colorado climate. He claimed for Denver (or the region for which it stands) the advantages of elevation, atmospheric dryness, a small annual precipitation, a cool climate, a prevailing mild wind of only moderate velocity, and an open sky.

HON. MARK W. HARRINGTON, chief of the Weather Bureau, read an exceedingly interesting paper on

SENSIBLE TEMPERATURES,

and exhibited charts in illustration.

In introducing his paper, Professor Harrington said, "The subject is so new that I am obliged to invent some terms to describe it." By "sensible" temperature, he explained, is meant that which is felt at the surface of the skin, especially where the skin is exposed as on the face and hands. To change a definite quantity of water from the liquid to the vapor state requires the utilization of a definite quantity of that form of energy which we call heat. On evaporation, this heat changes to other forms of energy; it is no longer sensible, and a sense of coolness results from its change. Thus is caused a reduction of temperature at the spot where the evaporation takes place; and while the evaporation continues, the surface from which it takes place is cooler than the general air-temperature.

The reduction of temperature caused by evaporation depends on the rapidity with which evaporation takes place, and this, in turn, on the amount of moisture already in the air. In general, when the air is saturated with moisture (that is, when the shade-temperature and dew-point are the same), there is no evaporation, and the reduction is zero. When the air is supersaturated, condensation, the reverse of evaporation, takes place, heat is released, and instead of a reduction we have an addition to the temperature. But when the air is not saturated, a reduction of temperature takes place.

The amount of this reduction will be greatest where the air is driest, least, where the air is moist. In Washington, Philadelphia, or San Francisco, the moisture is abundant, evaporation is relatively small, and hot weather feels hot. On the other hand, at Denver, Santa Fé or Prescott, the moisture is generally scanty, especially in hot weather, and the reduction is great. The most extreme case easily accessible is that of Furnace Creek, Death Valley, Cal. During the ob-

servations taken there in the summer of 1891, on five days the maximum temperature reached 122°; the temperatures of evaporation from 74° to 77°. The temperature felt by a person favorably situated was from 45° to 48° lower than that shown by the thermometer in the shade, and was almost cool for a summer afternoon.

It appears that in arid regions, the reduction may make hot weather not only endurable but even agreeable and refreshing.

So far it has been only a question of temperatures in the shade. Temperatures in the sun are always higher, and may be very much higher. On a hot summer afternoon, a temperature of 130° in the direct sun's rays is not rare in any latitude of the United States. Sometimes this temperature reaches 140°, and occasionally it is even higher. The conditions for sensible temperatures already stated do not apply in such cases — in part, it may be because of the failure of sufficient perspiration to give free evaporation; in part, because of the special effects which strong and direct insolation has on organic structures.

To obtain the beneficial effects of the reduction of temperature by evaporation, the shade must be sought, and the direct sun's rays avoided. The effects may be heightened by a natural or artificial breeze or wind; and for parts of the body covered by clothing they may be obtained by adapting the clothing to the free passage of air and moisture.

DR. JUDSON DALAND, Philadelphia, gave a detailed report of three cases of

BERI-BERI,

with examination of the blood. The greatest interest in these cases surrounds the question of etiology. Beri-beri has been observed in Japan, portions of Africa, and in the East and West Indies, and, as has been shown by Scheube and Baelz, it is an endemic peripheral multiple neuritis. Muira believed it to be due to fish, especially decomposed fish, while others attribute it to rice. These cases tend to bear out Muira's theory. The food of these men was almost exclusively fish and rice. Some of the fish was dried; much was spoiled; the quantity was insufficient. The main facts, as given by Dr. Daland, seem to point conclusively to poisoning by some substance in rice or decomposing fish, probably of the nature of misccarin.

These three cases recovered, as did eight others, sailors in the Brazilian navy, reported by Dr. Gihon.

Unfortunately, the time of the meeting did not allow for the reading in full of the paper of DR. DALY on

SOME PRACTICAL OBSERVATIONS ON SO CALLED MALARIA,

and that of DR. W. C. GLASGOW on

PHYSICAL SIGNS OF CELLULAR ŒDEMA OF THE LUNG CONSIDERED IN THEIR RELATION TO THE PATHOLOGICAL CHANGES.

A BIT OF MEDICAL CORRESPONDENCE. — A correspondent of the *Northwestern Lancet* sends the following letter received from a Dakota patient:

May 6th, 1894.

Dear Sir. I will write and tell You how he is he is just the same and his stomick bloth up and is so hard that he thing that it is gunt buts he is sick over his hole body and it sits up on under his brist but he is gat good opening in frant and behind.

Recent Literature.

An American Text-Book of Gynecology, Medical and Surgical. For Practitioners and Students. By HENRY T. BYFORD, M.D., J. M. BALDY, M.D., EDWIN B. CRAGIN, M.D., J. H. ETHERIDGE, M.D., WILLIAM GOODELL, M.D., HOWARD A. KELLY, M.D., FLORIAN KRUG, M.D., E. E. MONTGOMERY, M.D., WILLIAM R. PRYOR, M.D., GEORGE M. TUTTLE, M.D. Edited by J. M. BALDY, M.D., with 360 illustrations in text, and 87 colored and half-tone plates. Philadelphia: W. B. Saunders. 1894.

This is the most notable contribution to gynecological literature that has appeared since the publication of the "American System of Gynecology" in 1887. The high professional standing of the authors and the thorough manner in which they have utilized what has stood the test of time in this branch of medicine, and have given us the latest ideas on the various subjects treated, make it the most complete exponent of gynecology which we have. How long it will hold this position, in view of the rapid strides which are being made especially in this department is another question; until that time it will be looked to as an authoritative statement. Like a system of surgery published by the same firm, though of composite authorship, its various chapters are unsigned and the authors are as a body responsible for the views advanced. While this may have its advantages, yet where there is an editor-in-chief who can see that every part is adequately treated, and conflicting methods are not advocated, we think it is better for each author to accept the responsibility of what he has written. The average reader, especially of a subject where there can honestly be differences of opinion, naturally wishes to know who has made this or that statement, and such knowledge may add or detract from its value.

As a whole, the work has been well done as was to be expected, especial attention has been paid to the rules for and methods of antisepsis, to full descriptions of the technique of operations, including many new ones, and to the modern views of pelvic pathology. But no subject seems to have been neglected though the different parts vary in merit. Sometimes it seems as if the sense of proportionate value had been lost, but this is not strange when the natural bias of many of the writers is taken into consideration. Thus as between operative and non-operative methods of treatment, the former are sometimes, as it seems to us, given undue prominence, and this leads us to say that it is in no sense a text-book or primarily adapted for the student. It is too advanced and technical. But the gynecologist and surgeon and the general practitioner who has any desire to practise diseases of women will find it of practical value.

As we have read it through, there have naturally been statements with which we were not wholly in accord. Some few points have seemed worthy of mention. In Fig. 2 of the frontispiece the vulva is drawn much too high. The opening of the anus would more nearly represent its true position. The chapter on the "technique of gynecological operations" is excellent, though just what is gained by an illustration of a "patient being etherized," or of "washing away permanganate of potash with oxalic-acid solution" we fail to see.

In the chapter on the "examination of the female pelvic organs" too much space is devoted to the uterine elevator. Byford's is the best, but they are both dangerous and useless.

A separate chapter is devoted to "genital tuberculosis," a subject which has been neglected heretofore. It is thoroughly treated, beginning with lupus and following up the whole genital tract. As was to be anticipated, the author's treatment of the subject of inflammatory diseases of the uterus is thoroughly in accord with modern pathological views. The uterus is looked upon as the source of the trouble and as a result of this, they recommend that curettage of the uterus is indicated in every case of acute tubal or peritoneal inflammation where the source of infection has been in the uterus.

The chapter on "distortions and malpositions" is in general very good. We think the authors condemn too strongly the use of stem pessaries in the treatment of dysmenorrhœa associated with ante flexion, and are unwise in advocating the use of a repositior to replace the retro-displaced uterus. If Schücking's operation for a backward displaced uterus is "mentioned merely to condemn it," it is surely unnecessary to illustrate it with two cuts. The chapters on "malignant diseases of the female genitalia," and on "uterine neoplasms," are among the best in the book, and are very valuable to the operator.

In the matter of illustrations and plates the book surpasses anything we have seen. If we made any criticism we would say that some of them are unnecessary, and that except where it is essential to illustrate the point desired, absolutely nude figures are not in good taste. The book is well gotten up, and the letterpress admirable.

Minor Surgery and Bandaging. Including the Treatment of Fractures and Dislocations, Tracheotomy, Intubation of the Larynx, Ligation of Arteries and Amputations. By HENRY R. WHARTON, M.D., Demonstrator and Lecturer on Surgical Diseases of Children in the University of Pennsylvania, Surgeon to the Presbyterian Hospital, the Methodist-Episcopal Hospital and the Children's Hospital, Consulting Surgeon to the Presbyterian Orphanage. Second edition, thoroughly revised and enlarged, with four hundred and sixteen illustrations. Philadelphia: Lea Brothers & Co. 1893.

This work has quickly reached its second edition, and the author has revised the aseptic and antiseptic method of wound treatment, bringing them up to date; a number of new illustrations have been added. The book is divided into six parts. The first is on bandaging, the second on minor surgery, the third on fractures, the fourth on dislocations, the fifth on ligation of arteries, and the sixth on amputations.

The part on bandaging is illustrated by some beautiful half-tones, which add greatly to the text. A little more attention to detail in the description of some of the operations described would enhance the value of the book. Some of the illustrations are without value, except in so far as they stimulate the imagination. The book, as a whole, though, is one of the best minor surgeries that we possess.

On the authority of the *Hamburger Freisinnige Zeitung*, there were in Prussia last year, 1,200 individuals who died from delirium tremens, and 500 who committed suicide through intemperance.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, JUNE 28, 1894.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

 283 WASHINGTON STREET, BOSTON, MASS.

ZOLA AND LOURDES.

ZOLA's new novel, "Lourdes" is said to have been received with furor in Paris. It has been running as a serial through two of the leading daily papers. Though the book is ranked as fiction, the author has evidently pictured the scene in a realistic and on the whole, truthful aspect. The story of the miraculous appearance of the Virgin to Bernadette, a shepherd girl in 1858, and the erection of a great temple and sanitarium at Lourdes over the grotto, the scene of the apparitions; the innumerable pilgrimages of the sick to the spot; and the wonderful tales of sudden cures are familiar to all. The subject, moreover, has been recently reviewed in striking colors in two numbers of the *Revue des deux Mondes*, by Emile Pouillon, who insists on the reality of alleged miraculous cures.

Zola's tale opens with the description of a crowded train carrying sick pilgrims from Paris to Lourdes. There are patients there who for years have been bed-ridden; some are in the last stages of consumption; some have frightful lupus sores; some chronic eczematous eruptions; one passenger is at the point of death; one woman is taking her dying baby to be cured at the miraculous grotto; some are paralyzed. Just as the train leaves a certain station, a young girl gets on the car. She tells the story of the miraculous cure accorded to her diseased foot by simply dipping it in the water at Lourdes.

A vivid picture is given of the confusion when the invalids are landed at Lourdes. Hundreds of them are hurriedly conveyed in carriages and litters through the mud and dark to the big hospital until the procession shall be formed.

The hospital is greatly overcrowded. The sisters do their work heroically. At 8 A. M. the procession to the grotto is formed. The long line of invalids afflicted with every conceivable disease makes a horrible contrast to the beauty of the landscape. A priest

mounts the stone pulpit and asks the vast congregation to pray for a great miracle, as the body of the man who died on the train is to be immersed in the pool in hopes that life will be restored. The dead man is brought in and immersed amid vociferous supplications. No miracle occurs, and the corpse is taken away. The pool is thronged with sick persons, who eagerly await their turn. The supplications of the bystanders are of an urgent, imploring, sometimes almost of a scolding nature. Cures are demanded, that the honor of the grotto may be maintained, the good name of the importuned vindicated, that unbelievers may be convinced and converted.

So many are bathed in the pool that the water soon becomes filthy beyond description. The water in the pool is only changed twice a day, as the supply is somewhat scanty. No one better than Zola could describe the nastiness of the water, so seldom changed, in which so many persons suffering from cancerous and tubercular affections, purulent sores, ophthalmus, and offensive cutaneous diseases were bathed. "What a home for microbes," exclaims one of Zola's characters; "the present mania for antiseptic precautions receives a fearful blow from such a spectacle! How does it not happen that one nasty disease does not kill all the invalids?"

Zola, in a chapter lately published, describes a visit to the Bureau of Certifications, from which it would seem that there is a good deal lacking in the thoroughness of the methods of verification. The testimony of often unknown and obscure physicians was taken as to the condition of patients when they came for treatment; they were not subjected to a preliminary examination by a competent commission, and when any announced themselves as cured, there was always room for scepticism as to whether they had come to Lourdes with any serious malady, not amenable to cure by some strong psychical influence.

As to the percentage of "cures" effected at Lourdes, Zola estimates it as not more than 1.0 per cent., that is, nine out of every ten coming to Lourdes with faith and great expectations go away unrelieved; cases that expert physicians call clearly incurable are not benefited. As for the miracles occurring at the grotto, he is puzzled, and feels that probably a great mistake has been made somewhere. We conclude by giving a brief citation from the fourth chapter:

"Pierre began now to comprehend what this all meant — all that was taking place at Lourdes — this extraordinary spectacle at which the world had assisted for years, amid the devoted adoration of some and the mocking laughter of others. Certainly, the whole matter was very badly understood — almost ignored; but a hidden force moved it on — first the suggestion, then the perturbation of anticipation, the fascination of the journey, the prayers and the hymns, a growing exaltation and finally the healing breath, the unknown power that separated itself from the masses in a marked crisis of faith. He even fancied it rather stupid not to believe in these frauds. The facts themselves were very great, but at the same time far more simple. It was not necessary for the fathers of the grotto to condescend to lie — they must only needs add to the confusion to utilize the universal ignorance. They might even confess that all was done in good faith — the unknown doctors who gave the certificates, the comforted invalids who fancied themselves

cured and the enthusiastic witnesses who vowed they had seen. After all this it was evidently impossible to prove whether there had or had not been a miracle. From that moment did not the miracle become an actual fact to the larger number for all those who suffered and for those who had need for hope?"

REVISION IN THE AMERICAN MEDICAL ASSOCIATION.

WE call the especial attention of our readers who are interested in the evolution of the American Medical Association to the clear statements in the excellent letter on page 657 of this issue (from our special San Francisco correspondent). One finds therein not only a capital account of this individual meeting, but also a suggestive explanation of the forces at work to effect a modification in the government of the Association. An unavoidable delay gives our readers this letter later than we had hoped, but it is none the less readable on that account, and one sees more accurately after the smoke of the action has cleared away.

MEDICAL NOTES.

THE ROYAL SOCIETY OF EDINBURGH MEDAL. — The Royal Society of Edinburgh has awarded one of its medals to Prof. T. R. Fraser of Edinburgh University, for his work on strophanthus.

THE DECLINE OF THE MALE INTELLECT. — Again the senior wrangleship at Cambridge, England, has been obtained by a young woman, who is reported to have had a long lead over her male competitors. Her name is Johnson.

A MEDICAL CENTENARIAN. — Dr. Salmon, of Cambridge, South Wales, is the oldest physician in England. He was one hundred and four years old in May. He has a patient in the same town who is one hundred and five years old.

BOLD ADVERTISING. — The following advertisement appears in the *Münchener Medicinische Wochenschrift* of June 5th:

"TO THE PUBLIC. — I hereby take it upon me to make the welcome announcement to physicians that I have acquired the sole right of manufacturing the ANTICONCEPTION WADDING TAMPONS, according to the formula of Dr. —. See his pamphlet, "The Means to Prevent Conception," p. 29, published by — & —, price 1 mark 50 pf. I have them chemically prepared in different-sized packages. With respect and pleasure, —, Apothecary and Chemist.

"TAKE NOTICE. — Chemically prepared Anticonception Wadding Tampons. See page 29, etc."

Comment is unnecessary!

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — During the week ending at noon, June 27, 1894, there were reported to the Board of Health of Boston, the following numbers of cases of acute infectious disease: diphtheria 44, scarlet fever 35, measles 26, typhoid fever 15.

OPERATIONS AT THE BOSTON CITY HOSPITAL. — During the visit of the members of the Massachusetts

Medical Society to the Boston City Hospital at the recent meeting of the Society, the following operations were performed: an external urethrotomy, an appendicitis, two hysterectomies and a complete removal of the breast and glands of the axilla.

HONORARY DEGREE. — Dr. D. W. Cheever, Emeritus Professor of Surgery in the Harvard Medical School, received the degree of LL.D. from Harvard College at Commencement, June 27th.

HARVARD MEDICAL ALUMNI ASSOCIATION. — The Harvard Medical Alumni Association held its annual meeting and annual dinner, in Boston, on Tuesday, June 26th, at 12 and 1 o'clock. The usual routine business was transacted at the meeting. At the dinner, at which presided most felicitously Dr. James R. Chadwick, Dr. W. W. Keen, of Philadelphia, Dr. Wm. Osler, of the Johns Hopkins University, Dr. W. M. Polk, of New York, and Dr. J. S. Billings, U. S. A., made speeches. A full report of the occasion, which was one of much interest, will be given later.

HARVARD DENTAL ALUMNI ASSOCIATION. — The Harvard Dental Alumni Association held its twenty-third annual meeting and its annual dinner at the Hotel Thorndike, Boston, Monday evening, June 25th. Dr. Virgil C. Pond, President of the Association, presided; and after the dinner speeches were made by Bishop Lawrence, of Massachusetts, Mr. Thomas, Private Secretary of the Governor of the State, Dr. George B. Shattuck, of the Board of Overseers of Harvard College, and Mr. W. R. Thayer, Editor of the *Harvard Alumni Magazine*. The Association is in a flourishing condition.

THE ANNUAL ADDRESS IN MEDICINE AT YALE UNIVERSITY. — The Annual Address in Medicine before the Medical Faculty of Yale University, was given by Dr. William T. Lusk, on Tuesday, June 26th. Dr. Lusk chose as his subject, "The Illustrious Boerhaave." Prof. William H. Carmalt gave a reception to Dr. Lusk in the evening of the same day.

TUFTS MEDICAL SCHOOL COMMENCEMENT. — At the commencement exercises of Tufts College held on June 20th, the degree of Doctor of Medicine was conferred upon the first class to graduate from the medical school of the college. Seventeen persons were given degrees. An honorary degree of LL.D. was conferred upon J. S. White, of Brooklyn, Dean of the Long Island Hospital Medical School.

THE MASSACHUSETTS INFANT ASYLUM. — The twenty-seventh annual report of the Massachusetts Infant Asylum, shows a most successful year's work. Of 88 children in the hospital but five died, two of bronchitis in the hospital, and three who were out boarding — one of bronchitis, one of enteritis, and one of convulsions of unknown origin. During the twenty-seven years of its existence the hospital has cared for nearly 3,700 children, with a total mortality of only 468, or less than 18 per cent.

PROTESTS AGAINST THE CONTINUANCE OF TWO HOSPITALS. — The Committee on Health of the Board

of Aldermen of Boston, gave a hearing last week to the remonstrants against the licensing of the Baptist Hospital on Bellevue Street, Longwood, and of the Free Consumptives' Home on Quincy Street, Dorchester. The hospital having withdrawn its petition for a license for a lying-in department, no especial permit is required for the carrying on of a general hospital. The Board, however, has statutory power to prohibit hospitals in any particular portion of the city; and it is this restrictive power which the remonstrants desire the Board to exercise, on the ground that both hospitals are situated on residential streets to the disadvantage of property owners.

NEW YORK.

THE TENEMENT-HOUSE POPULATION.—Dr. Roger S. Tracy, Deputy Registrar of Vital Statistics, has just completed the semi-annual census of the tenement-house population of New York, and his report was presented at a meeting of the Board of Health held June 19th. It shows that the total tenement-house population is 1,832,773, and that the total number of tenement-houses is 89,138. Of this number there are 2,346 rear houses, and the population of the latter amounts to 56,130. In the ward which contains the largest tenement-house population (the twelfth) there are 7,702 tenement-houses, with a population of 252,381; and in the ward which contains the smallest (the second), there are 8 tenement-houses, with a population of 175. The total number of children under five years of age residing in tenement-houses in the city, is 180,359.

SMALL-POX AND CHICKEN-POX.—A short time since some cases of eruptive disease occurring at Stapleton, Staten Island, were pronounced by the local health officer to be chicken-pox. Some of the other Staten Island physicians believed these cases to be really small-pox, and with the consent of the health officer, Dr. A. H. Doty, Chief of the Bureau of Contagious Diseases, and other experts from New York, were asked to examine the cases. They unhesitatingly expressed the opinion that the disease was small-pox, and the health officer, although not convinced, promised to take all possible precautions in the way of quarantine and disinfection. The matter having been brought to the attention of the State Board of Health, representatives of that body visited Stapleton on June 20th, and reported that the cases were undoubtedly small-pox, and on the day following, at the request of the State Board, Dr. Bryant, of the New York City Health Department, was sent to Stapleton to take charge of the disinfection of the premises where the cases had occurred, and to direct the vaccination of all persons who had been exposed to the disease.

TREPHINING FOR HEADACHE.—At a meeting of the New York County Medical Association held June 18th, Dr. J. Marshall Hawkes presented a patient, a young man, whom he had trephined for persistent localized headache. In Starr's recent work on "Brain Surgery," Dr. Hawkes said it was stated that this op-

eration had been performed but twice for the purpose in question, once in London, and once in New York, by Dr. Robert F. Weir. From early boyhood this patient had suffered intolerably from frontal headache, and though he had consulted a large number of physicians, every remedy that had been tried had utterly failed to give him relief. Thinking that the trouble might possibly be due to eye-strain, Dr. Hawkes first sent him to Dr. H. Knapp, but the latter found that there was no difficulty of this kind. On making an examination of the head, the only abnormality that could be detected was a slight indentation of the bone in the right frontal region. As a last resource, Dr. Hawkes determined to trephine at this spot, and on June 30, 1892, a button of bone, about two-thirds of an inch was removed under strict antiseptic precautions. It was found that in the location named there was a depression of the inner table of the cranial bone, making pressure upon the brain substance, and the button removed was exhibited to the Association. From the time of the operation there had been complete relief from the headache, and as two years had now elapsed, the cure could be pronounced permanent.

Miscellany.

THE FIRST DISPENSARY.

In an account of the development of the Hospital Sunday Fund, the *Lancet* relates the story of the establishment of the first dispensary. "In 1696, an instrument was signed by the President of the Royal College of Physicians, most of the Elects, Senior Fellows and Candidates, declaring that 'no method hath been taken to furnish the poor with medicine for their cure at low and reasonable rates,' and subscribing sums of money to be 'expended in preparing and delivering medicines to the poor at their intrinsic value.' Notwithstanding 'the vigorous opposition of a few men who thought it their interest to defeat so laudable a design,' a dispensary was erected in Warwick Lane 'being an apartment in the College set up for the relief of the Sick Poor,' and managed for many years with integrity and disinterestedness. It was of this that Dr. Garth wrote:

"There stands a dome majestic to the sight
And sumptuous arches bear its oval height;
A Golden Globe placed high with artful skill
Seems to the distant sight a Gilded Pill."

JAPANESE GIRLS IN BOXES.

THE beauty of Japanese girls is proverbial, and their attractiveness led recently to an attempt to smuggle some of them out of their country to become the slaves of their purchasers.

According to the report of the officers of the Northern Pacific steamer *Tacoma*, just as that vessel left Yokohama on a late trip, a Japanese man came on board with four large boxes, which he said he wished put in the steerage as his luggage. Just as the first box was about to be lowered a rapping and faint cry was heard from one of them, and on opening it a young Japanese girl was found doubled up inside. Each of

other boxes was found to contain a similar Danæ, but all of these three were unconscious. After several of them were resuscitated, but the third was moribund when discovered and soon died.

On police investigation the responsible agent was not found, but the Japanese woman who had enticed the girls to her house and drugged them was discovered. It is said she has a husband in Portland, Oregon, to whom the girls were consigned.

It had been planned that the steerage passenger would open the boxes after the vessel left the Japanese waters and release the girls, paying any fare which might be required. Three air-holes had been bored in each of the boxes, but these had become almost closed by the bodies of the girls, which were crowded into the coffin-like confines in a cruel manner. Each box was two feet three inches in length, and about eighteen inches in depth and breadth. In each of the boxes was a piece of bread.

Correspondence.

[From our Special Correspondent.]

LETTER FROM SAN FRANCISCO. THE MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

ATTENDANCE.—WORK IN GENERAL SESSIONS AND IN SECTIONS.—CHANGES IN OFFICERS.—CENTRALIZATION.—REVISION OF THE CONSTITUTION. THE CODE.—ENTERTAINMENTS AND HOSPITALITIES.

SAN FRANCISCO, June 11, 1894.

THE forty-fifth annual meeting of the American Medical Association has been voted a scientific and a social success. In point of attendance it has exceeded many former meetings held in populous eastern centres, nearly 600 members having been registered in attendance. The greater number of the sections were well organized, those failing to make a good showing being usually in a similar position. Even the section on Oral and Dental Surgery, that had been the despair of its energetic officers, was well attended and had ample material for its consideration. The section on Surgery had been assigned quarters in Memorial Hall which would accommodate 300 persons, but even this was found too small at times, and this interesting section, which had much more material than it could dispose of, was shifted to the hall in which the general sessions were held. The section on Medicine and that on Obstetrics and Diseases of Women were always well attended. In fact, throughout the meeting a genuine and lively interest was taken in the scientific work, which was excellent in character.

Of all the western cities none can surpass San Francisco in the facilities she presents for the entertainment or for the reception of a large gathering, such as the American Medical Association. Her hotel accommodation is of the best, and of that which is strictly first-class there is always plenty to be had. The position which this city has long held as the metropolis of the Pacific Coast has created a demand for all that goes to make up a large city in a more populous region. Her halls are numerous and commodious, and of amusements and points of interest to the visitor there is no lack. The only thing therefore required to make the meeting a success were an ample attendance and efficient preliminary work on the part of the committee of arrangements. The visitors came, and the committee certainly did its work in a most thorough manner.

Twenty-three years is a long time in the life of a man or of an organization. To paraphrase the statement of the Governor of Carolina, "It is a long time between meetings." During this interval the membership derived from

the former meeting had died off or dropped out, only a few of the "old guard" remaining, supplemented by additions mainly by application. When, therefore, the Association decided to go to California the chairman of the committee realized that he had a large contract on his hands; and after some consultation with his committee he started East on an educational tour. When fully informed as to the machinery of the meeting, it was next necessary to map out all the detail work and to instruct every one in his particular task. When these facts have been taken into consideration, the committee must certainly be congratulated on the very successful results of its labors. The attendance was good, and indeed more than the most sanguine anticipated, amounting in all to something like 1,200; but it is now certain that more prosperous times would have largely increased these figures.

The phenomenal weather was also an unfavorable factor. At the last moment many who intended to go were afraid to start. Some already under way failed to reach San Francisco in time for the meeting. To crown these uncertainties, it was announced at headquarters that the Association train, with the President and many of the officers, was "stalled" in Colorado, unable to proceed and with some reason to fear that it could not return. This train was ultimately rescued; and the belated travellers, after two days delay, reached California by the southern instead of the northern route. The railroads made the best of the situation, the California company giving the train the right of way in its territory and getting it in five hours ahead of schedule time. "All's well that ends well," and most of the travellers were on hand for the opening of the meeting.

The Palace Hotel, the largest in the city and centrally located, had been selected as headquarters. The registration bureau was located in one of the large halls of the hotel, and in an adjoining hall was the ladies' headquarters, a feature that contributed in no little degree to the pleasure of visitors. Previous to the meeting a ladies' committee had been appointed, whose duty it was to look after visiting ladies and provide for their entertainment. During the entire session members of this committee were on duty at headquarters, and all were made to feel at home. The registration bureau, though hard pressed at times, did effective work and did not break down. It was, during the busy hours, often a little behind; but no flagrant mistakes were made, which is somewhat creditable where all were new to the work. Here, as in every other department, the local committees may be said to have been swamped. The most sanguine had not calculated on so large an attendance, and the friends and relatives accompanying the members were an agreeable though unexpected surprise. While supplies of all kinds had been, as was supposed, liberally provided, fresh requisitions were demanded; and it was even necessary to reprint the entire programme, to provide for new arrivals.

A majority of the visitors found quarters at the Palace, and here also rooms were provided for the committees. The general sessions, all the section meetings and the exhibition were housed in the Odd Fellows' Building. The whole building had been engaged, and was ample for the purposes of the Association. On the ground floor, which was lighted by electricity, a very fair exhibition attracted the attention of the members during their leisure moments in the day. Immediately above was the main hall in which the general sessions were held, and here also the section on Surgery was compelled to seek better accommodations. This had been very tastefully decorated by the local committee, greatly enhancing the effect of the fine hall and materially improving its acoustic properties. Exclusive of committee-rooms there were twelve halls, so that every section was enabled to meet under the same roof. This seemed to give general satisfaction, and while uncommon in the past, should be adopted in every city offering equal facilities. The main hall was well filled at every general session, members and spectators alike anticipating interesting debates.

Dr. Hibberd as a presiding officer earned a well-deserved

popularity. His decisions were prompt; his rulings on debatable points, if a trifle arbitrary and at times not strictly parliamentary, were always well received. His unfailing good humor and ready wit invariably carried the large audience with him, and enabled him to quickly discomfit any opposition that might be manifested. Even in the midst of the heated debates on Constitution and Code, his unfailing good humor disarmed the contending factions, and more than anything else contributed to lessen asperities and to promote harmony throughout the entire meeting. His address, a really presidential message, was broad and comprehensive in character, and was well received. In it he outlined the neutral position he proposed to occupy on the question of revision, at the same time pointing out the feasibility of speedily terminating controversy. His recommendations were heartily concurred in by the Association.

Many will regret the resignation of Dr. R. J. Dunglison, who has for seventeen years been Treasurer of the Association. It is said he resigned to anticipate a movement to oust him that was rather prominent at Milwaukee. It was also hinted that he had not come to California, not desiring to be present at his own funeral. It was further rumored, and had even been published, that Dr. W. B. Atkinson's official demise had been discussed; but the ceremony failed to materialize, and the venerable Secretary has entered upon his thirty-first year of office. It appears that all this is part of a policy of centralization that would place the executive officers of the Association in Chicago. This, no doubt, would facilitate the conduct of the *Journal*, but might be regarded with suspicion by a large number of the Association, which fact it would be well to bear in mind.

As a feature of the meeting of 1894 the general addresses were a failure. That in Medicine, by Dr. Hughes, as a literary composition might be commended; but it was abstruse and theoretical, and above all unpardonably long. When will the readers of papers learn that the average audience can only be held attentive by profoundly interesting topics, briefly stated! The remaining addresses in Surgery and in State Medicine were not read, the authors being absent, and the papers also being out of reach. It is true that more interest will attach to an address when delivered by the author, but in his unavoidable absence there is no reason why the meeting should be deprived of so important a paper, which can be read by the Secretary or by a reader of the author's selection. As it happened, the business of the sessions so fully occupied the time that the remaining addresses could only have been read by prolonging the sessions.

The sensational feature of the meeting, and one on which interest concentrated to the exclusion of all else, was the question of revision. The reports of the committees on Constitution had virtually been before the country for twelve months. A proposed Constitution and By-Laws had been submitted at Milwaukee, and it was well known that certain changes were to be made in the Code. At both meetings when these reports were considered, the hall was filled to its utmost capacity, a number of ladies and a fair representation from the medical students being present in the galleries.

Whatever may be said to the contrary, it is quite plain that the revisers of the Constitution have in mind a concentration of power in the hands of a few, with every indication that this control would be self-perpetuating. Without for an instant impugning their motives, it must be plain to any thinking man that such a result will inevitably be reached. The president is an outspoken revisionist; but it is difficult to realize the soundness of his argument, that from the mode of its election, the business committee must be representative. It is quite true that it is representative of the profession, in the sense that its components are representative men or leaders in the profession. It is also true that by virtue of that fact they are leaders in different branches, or specialists, and equally true that there never will be a general practitioner amongst their number and that he would find no place there. The business committee

has charge of the scientific work of the meetings, it fulfils its function admirably, but it should not be embarrassed by outside matters. These are the weak points of the proposed Constitution, and they found no favor with the Western men.

It was sought to remedy this defect by two propositions: First, that there should be added to the business committee for the purposes of nomination, a representative from each State and Territory. This, while making a very unwieldy committee, would leave things just where they were, as the voting power by numerical superiority would still rest with the business committee. The second proposition would in a few years decide the whole matter in favor of the revisionists. This is to enable every man who has attended twice as a delegate to have the right to vote in future. The inevitable result of this would be to provide a greatly increasing majority of the voters in the Eastern and Central States, and to leave the West hopelessly out in the cold. It is therefore hardly to be wondered that neither change found much favor with the Western men who were averse to committing suicide on the question of representation. Whatever may be the defects of the Constitution proposed by the minority, it was certainly more in consonance with the feelings of the Pacific Coast States, and it is beyond question that it could have been adopted at this meeting. The management of the subject was, however, bad; the supporters of the minority were unaware of their strength or feared to trust themselves, and the tactics of the opposition were certainly superior. As a result, the matter has been deferred for two years, to come up anew, when decisive action would have given the Association the benefit of a trial of the new Constitution.

On the question of a change in the Code, opinions were even more radically divided. The supporters of a new Code in the great West, and particularly on the Pacific Coast, are few in number. The great mass of the profession desire no change, and are perfectly satisfied with the Code as it is. It can hardly be regarded as a matter of sentiment, but rather as being due to a clearer conception of the honesty and fairness as well as of the ethics of the Code. That no change could be effected at the San Francisco meeting was a foregone conclusion, when the Medical Society of the State of California expressed itself as opposed to any change and instructed its delegates to so record their votes. Several of the local societies had also recorded their vote as opposed to change, and those which had not taken formal action were none the less opposed to iconoclastic measures.

Whatever misconception may exist in the Eastern States on the question of consultations, there is certainly none in the Far West. An irregular practitioner or sectarian physician is recognized as such, his honesty and conscientious practice duly respected, or his dishonest methods properly appreciated. Hence there is no association, except by a very few black sheep, nor has the leaven of commercial greed penetrated very deeply. Outside the question of consultation, there is no point except that concerning the holding of patents by physicians on which there could be much controversy. While there are many who feel that a physician should be allowed, if he so desire, to obtain a patent, the majority certainly believe that the present course is the most respectable and professional.

There was an expression of general satisfaction and hearty good-will to do right when the vote on revision of the Code was taken. It was perfectly within the power of the supporters of the Code to have carried the adoption of the minority report by a large majority; but here, as in the case of the Constitution, affairs were mismanaged, and at times many of the delegates did not know how they were voting. There is, however, a temporary cessation in hostilities, and every one parted in very good humor.

In the matter of entertainments California's hospitality cannot be said to have been at fault. The medical societies, the medical schools, private individuals, and, in fact, the whole profession seemed most fully to appreciate the visit of the Association. In several cities in which the Association has been entertained in recent years it has been cus-

ary to solicit contributions from citizens towards an rtainment fund. In this manner large sums have been ed. It was early determined that such methods would be pursued in California, and the decision was reached imit subscriptions to medical societies and members of profession. In spite of hard times a liberal response made, and the committee found itself with ample funds hand. During the short period of four days, with only evenings for pleasure, it was necessary to apportion the ie so as to allow all that were desirous of entertaining, an opportunity to do so.

The ladies were not forgotten, special features being ranged for their amusement during the hours devoted to identic work. Of these the most enjoyable were: a ive through Golden Gate Park, returning by the Presidio id Ocean Beach, and a "tea" at the residence of Mrs. R. . McLean, that showed the visitors a charming home in ie most attractive residence section of the city. On Fri- ay, June 8th, Mr. Adolph Sutro, whose daughter Mrs. G. V. Merritt is a physician, entertained some 300 ladies at inch. Refreshments were served in a large pavilion which will be part of the baths) below Sutro Heights and lose to the famous Cliff House, which Mr. Sutro is estab- lishing on a stupendous scale.

The general entertainments were as follows: commencing with an informal instrumental concert at the Palace Hotel on Monday evening, the San Francisco County Medical Society opened the festivities on Tuesday with a reception at Pioneer Hall. The whole building, including the State Mining Bureau, was open to the visitors and many relics of early days were to be seen. On Wednesday evening Cooper Medical College kept open house at the college building, corner of Webster and Sacramento Streets. The Lane Hospital adjoining, now almost completed, had been temporarily lighted for this occasion, and the several hundred people inspected everything, from auditorium below to dissecting-room on the fourth floor. On the same evening Dr. W. F. McNutt gave a reception at his residence, 1805 California Street. On Thursday afternoon and during the early evening, Dr. L. C. Lane gave a reception at his residence, corner of Clay and Buchanan Streets. Later in the evening the Association, as a "committee of the whole," visited the Mid-Winter Fair. The evening was fortunately very pleasant, there being very little wind, and the Court of Honor was thronged with the Association, members being found at every turn. This was a special occasion; and after sufficient time had been allowed for a thorough inspection, every one repaired to Festival Hall, where refreshments were served and some short speeches were made by the Director-General M. H. De Young, Dr. R. Beverley Cole and others, not omitting Dr. H. O. Marcy. On Friday evening the Medical Department of the University of California gave a very elegant reception at the Hopkins Art Institute on Nob Hill. This palatial mansion, originally built by Mark Hopkins, one of the famous four who planned and constructed the Central Pacific Railroad, is now, through the munificence of Mr. Edwin F. Searles, of Great Barrington, Mass., the property of the University of California.

Saturday had been reserved for the entertainment by the medical profession of the State of California. This took the form of an excursion on the bay; and at 9 A. M. the steamer *Newark* started with over 1,200 persons on board. All points of interest in the lower bay were visited, then passing the quarantine station, the steamer headed for Mare Island, where about two hours were spent ashore visiting the U. S. Navy Yard and inspecting the hospital and the coast-defence vessel *Monterey*, which with other war-ships was anchored off the yard. The homeward trip was made without incident, though the water was not as smooth as it should be at this time of year.

On all sides are heard words of commendation for Dr. R. H. Plummer and the local committees, whose management has been very successful. On the other hand, Californians are unanimous in expressing the hope that the Association will not wait twenty-three years before it revisits the western shores of its territory.

METEOROLOGICAL RECORD.

For the week ending June 16th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Date.	Baro- meter	Thermom- eter.			Relative humidity.		Direction of wind.		Velocity of wind.		Weath'r.		Rainfall in inches.
